The majority of the Arachnida feed upon insects, which they seize alive, or upon which they fix themselves, and from which they suck the juices. Others live as parasites upon the bodies of vertebrated animals. There are some, however, which are only found in flour, cheese, and upon various vegetables. These last, which mostly belong to the tracheary order, exhibit an affinity to Insects not only in their structure but in their metamorphosis; for they undergo great changes after they come out of the egg, an additional pair of legs being often developed; whilst in the others nothing else than a moult or casting of the skin occurs.

Order I.—Trachearia.

The Trachearia, being the most nearly allied to Insects, are naturally the first to be considered. This order contains several remarkable forms, of which the one best known is that of ACARIDÆ, or Mites, the majority of the species of which, however, are very minute, or almost microscopical. They are very extensively distributed; some being wanderers under stones, leaves, the bark of trees, in the ground, or upon articles of food; whilst others subsist as parasites upon

Acarus Domesticus magnified. (Mite.)

the skin and in the flesh of different animals, often greatly weakening them by their excessive multiplication. There are some species which infest insects, especially the carrion beetles. Some of this tribe much resemble spiders in form and habits.

Besides the *Acari*, which form the principal part of this order, there is a curious group, which has received the name of *Pseudo-Scorpions*, owing to their possession of a pair of large claws terminating in forceps, which, like those of the true scorpions, are formed by an excessive development of the organs which in insects are termed palpi. There is also a very curious family, which some naturalists have separated into a distinct order, the *Pycnogonides*; these are distinguished by the absence of all special respiratory organs, and in their aquatic habits bear a strong resemblance to Crustacea. They are found amongst marine plants, and under stones on the beach. Their motions are remarkably slow; and they are said to live chiefly upon the animals of Bivalve Mollusca.

Order II.—Pulmonaria.

In this order, the respiration is performed by means of air-sacs contained on the under side of the body, and opening externally by stigmata; sometimes these apertures are eight in number, four on each side, but sometimes four, or even only two. This diminution appears to indicate a gradual elevation in the character of the apparatus; leading us from the diffused condition in which it exists in Insects, to the more concentrated form it presents in higher animals. The Scorpions possess eight breathing-pores; and thus approach nearer to the Tracheary Arachnida than do the Spiders. They offer themselves next, therefore, to our consideration.

The family of PEDIPALPI is distinguished from that of Araneidæ principally by the great development of the palpi, which form extended arms, terminated by a pincer or claw. The entire body is clothed with a hard skin. In the *Scorpions*, which constitute the principal part of this family, the abdomen is very much prolonged, forming a sort of tail, which is terminated by a sting furnished with a venomous secretion. The wound of

Scorpio Occitanus.

this sting, although very painful, does not seem to be ordinarily dangerous. A small species inhabits this country; but it is between the tropics that the Scorpions attain their greatest development. They usually live on the ground, hiding themselves under stones or other bodies, among ruins, where such exist, and dark and cool places generally, even the interior of houses. They run quickly, and curve the tail over the back. They can turn it as an arm of offence or defence.

Besides the Scorpions, there is included in this family the tribe of *Tarantula** Spiders, which seem intermediate in several respects to the Scorpions and true Spiders.

The other family of the pulmonary Arachnida consists only of the Spiders of various kinds, and is designated ARANEIDÆ. In these, the palpi are not developed to any thing like the same degree as in the Scorpion tribe; they rather resemble feet; but the jaws are armed with sharp and hooked fangs, and are perforated near their points, for the emission of a poisonous secretion provided for the destruction of their prey. Nearly all of them are provided with organs, situated at the hinder part of the body, for spinning a very delicate silken

* These are not the animals known in the south of Europe under the name of *Tarentula*, receiving their designation from the city of Tarentum; the latter are true Spiders.

thread ; but the use to which it is to be applied varies in different species. In some it forms webs in which are entangled the insects on which they feed ; in others, it is employed to make a delicate silken tube, which lines their habitation ; and in others, it is chiefly used for the fabrication of a sort of cocoon with which the eggs are surrounded. The instruments by which this thread is produced are little teat-like protuberances, termed *spinnerets*, of which four usually exist at the posterior extremity of the abdomen. Each of these, when highly magnified, is found to be perforated at its extremity by innumerable orifices of extreme minuteness, through which is forced out a glutinous fluid, secreted by glands within. This fluid soon hardens by exposure to the air ; and thus each thread, delicate as it may seem, is composed of several hundreds, of extreme minuteness, coiled together, so that it possesses great strength in proportion to its diameter.

The Spiders are all extremely voracious in their habits, feeding only upon prey which they have themselves killed. When they have got an insect between their claws, either by entrapping it in their web or by their stealthy mode of pursuit, they plunge their poisoned mandibles into its body, and the bite is usually soon fatal. Sometimes, however, the insect has strength enough to resist its enemy, and to prevent the infliction of the fatal wound ; and, as a prolonged struggle might be very injurious to the spider, on account of the softness of its body, it generally retires from the contest if not speedily successful. Where its prey has been entangled in its web, however, the spider still further encloses it by a silken thread, and then retires until the insect has lost its strength by ineffectual struggles, when it soon dispatches its victim.

The Mining-Spiders, found in the South of Europe, construct, in dry shelving situations exposed to the sun, subterranean cylindrical galleries, often two feet deep, and so tortuous, that the traces of them are lost. These they line with a silken tube, forming at its entrance a moveable lid, composed of silk and earth, attached to the silken lining by a sort of hinge ; and this is adapted, by its size, situation, and weight, to close the opening so precisely, as scarcely to allow its entrance to be distinguished from the neighbouring soil. When the spider enters its retreat, or passes out of it, the door shuts of itself. The *Mygale* spins a sort of cocoon round its eggs, enclosing a hundred or more ; they are hatched within it, and the young undergo their first changes before quitting it.

The *Clotho* is remarkable for the curious habitation which it constructs for its young. It spins a kind of circular cocoon or tent, which it attaches to the under side of stones or to crevices in rocks by seven or eight points, leaving festoons between these, the edges of which are free. At first this consists of only two folds, but others are gradually added ; and beneath them all a lining of peculiarly soft texture is constructed for the reception of the eggs. The young remain in this for some time after they are hatched, and are supplied by the parent with food. The *Argyroneta* forms a winter retreat for itself beneath the water. It spins an oval silken chamber, open at the bottom like a diving-bell, which it attaches by cords to water-plants. It then carries down successive bubbles of air beneath its body, by crawling down their stems ; and these bubbles it transfers to its bell until it has filled it. It then takes up its abode in this cell, where it remains for the winter, first closing the mouth of the bell. The *Epeira* are among the most remarkable for the strength of their webs ; some of the exotic species, which are remarkable

for the variety of their forms, colours, and habits, spinning nets which are sufficiently strong to catch small

Epeira Diadema.

birds, and even to annoy man when he happens to come in the way of many together.

CLASS VIII.—CRUSTACEA.

The animals composing this group may be regarded as representing in the sea the insects and spiders of the land. Indeed, they were associated with those classes by Linnæus, in his class of Insects. But they are separated from both by very important characters. Their chief distinction is in the breathing apparatus, which is adapted to aquatic and not to aerial respiration. Instead of the system of branching tubes which we find in Insects, or the lung-like cavities which are a more concentrated form of the same structure in the Arachnida, the Crustacea are furnished with fringes of gills like those of the Mollusca or Fishes, into which the blood is sent, as it were, out of the body, to meet the small quantity of air contained in the surrounding water. In the highest order of this class, the gills do not hang loosely from the body, but are enclosed in a cavity, having two orifices, through one of which a constant stream of water is introduced, which is ejected through the other by a curious mechanical contrivance. And in a few species of this order, there is a special provision for keeping the gills moist when the animal leaves the water, out of which it can live for a considerable period. The best-known of these are the Land-Crabs of the West Indian Islands.

It is not only by their aquatic respiration, however, that the Crustacea are distinguished, but also by the calcareous nature of their integument. The shell, as it is commonly termed, is a secretion from the surface of the true skin, just as are the shells of Mollusca from their mantle. There is this important difference, however, between the two, that, whilst the latter is merely adapted to enclose loosely and to protect the general mass of the body, so that the locomotive appendages, when put in action, must be made to project beyond it, these being themselves unsupported by any hard skeleton, the former accurately fits not only the trunk but the extremities also, and, as in the other Articulate, is composed of a number of rings, more or less regular in form, and accurately jointed together by an intervening membrane.

As no addition to the edges of these rings would increase their diameter, some other means must be provided for enabling the size of the shell to keep pace with the increasing bulk of the body. This is effected by the periodical *exuviation*, or throwing off of the old shell, and the formation of a new one. This change is preceded by evident illness on the part of the animal, which retires to its hiding-place at the time. The part of the shell enclosing the trunk splits usually at its under part, in such a manner as to allow the body to escape ; but the shell of the legs and claws remains entire, though the fleshy parts are entirely withdrawn from their interior. This is the more remarkable, as the bulk of the claw is much greater than the diameter of the joint through which it is thus made to pass ; and

Mygale Fodiens.

often the disproportion is extreme. When the shell has been thus thrown off, the animal is entirely unprotected, and it carefully conceals itself from its enemies. Its soft skin is soon covered, however, with a sort of mucous exudation, which contains a large quantity of calcareous matter, and speedily hardens. The re-formation of the shell is facilitated by a store of carbonate of lime previously laid up in the stomach, where it forms the concretions commonly known as *crab's-eyes*; these disappear at this period, being absorbed, and then excreted on the surface of the skin.

The power possessed by the Crustacea of repairing injuries, is very remarkable in beings of such high organisation. In the process of exuviation, it is not uncommon for a part of a claw to be lost; and this is speedily replaced by a new one. The second joint from the body is that at which the fracture most commonly occurs; and it is probably the only one from which the new growth can issue. For, if the claw be broken off below that point, the animal itself effects the removal of the upper portion, either simply casting it off by violent muscular contraction, or striking it against some hard body. The same is the case when the claw has been accidentally lost in some other way; and, accordingly, it is by no means uncommon to witness a great disproportion in the size of the two members, one being much smaller than natural, from its having been only recently produced.

The number of legs possessed by the Crustacea is greater than that of perfect insects, being never less than four pairs, besides the pair of claws which may be considered as metamorphosed legs. It is in the crab, lobster, crayfish, &c., that we find this small number; and these belong to the highest order, the Decapoda, or ten-footed Crustacea. In front of these are some curious organs termed feet-jaws, being intermediate in structure between these two kinds of appendages; in some of the lower Crustacea these become true legs. And from the posterior part of the body there hang down certain appendages, which are also true legs in the lower orders. In fact, the lowest Crustacea approach very closely to the Myriapoda in their general form and structure, differing chiefly in their aquatic mode of life; the segments of the body are nearly equal, and are each furnished with a pair of legs. On the other hand, among the Decapods we find an approximation to the form both of insects and spiders—the lobster representing the one, and the crab the other. In the lobster we have a regular division into *head, thorax, and abdomen*, as in insects; and it is to the thorax alone that the locomotive appendages are attached, as in the perfect state of the insect. There is no rudiment, however, of wings. As in the insect, we find that, where the force is concentrated in one part of the body, and the general movement is effected chiefly by the members, the segments of that part are consolidated; and, accordingly, the thorax of the lobster seems, until carefully examined, as if composed of a single piece. The segments of the abdomen, however, are moveable on each other; and their motions assist in progression, the flattened tail serving as a fin by which the water is struck. In the crab, the head, thorax, and abdomen, are all consolidated into one mass; but the division into segments is still evident on the under side.

As in all other Articulata, the eyes of the Crustacea are compound. Their external coating is thrown off with the shell; and this, when examined with the microscope, is seen to exhibit the division into minute lenses with beautiful distinctness. By its transparency the cast shell may be at once distinguished from one in which the animal has died. It is interesting to find this structure preserved in great perfection in a curious fossil tribe of this class, the *Triobolites*, the compound structure of whose eyes, mounted as they are upon short footstalks, is at once distinguishable with a magnifying glass, proving them to have been articulated animals, even if no other evidence existed to that effect.

Owing to the great varieties of structure which this class includes, its division into orders appears very

complex. Thirteen are established by M. Milne-Edwards, the characters of which will now be generally stated. As many of them, however, contain but a few species, of which little is known, a more detailed account will be given of those only which possess more universal interest.

The class Crustacea may be separated in the first instance into two divisions. In one of these, including the great bulk of the class, the mouth is furnished with organs specially destined for the prehension or division of the food. In the other, there are no special organs for the purpose, the bases of the neighbouring legs serving the purpose of jaws. This *second* division contains but one order, the XYPHOSURA, and this contains but one genus, the *Limulus*, or King-Crab, which will hereafter be noticed in detail. The *first* division is then separated into two groups—one, the MAXILLOSA, having the mouth furnished with jaws; the other, the EDENTATA, having the mouth prolonged in the shape of a sucker. These two groups are precisely analogous to those of Mandibulata and Haustellata among insects. The EDENTATA are divided into three orders, according to the form of the extremities:

ARANEIFORMES, in which the extremities are rod-like, long, and adapted for walking.

SYMPHONOSTOMATA, in which the extremities are not adapted for walking, are partly formed into plates, and partly adapted for prehension.

LERNEIFORMES, in which the extremities are but little developed, and the body presents great variety of form. Most of these are parasitic upon other animals, especially fishes, to which they cling by means of hooks in which their rudimentary extremities terminate.

The MAXILLOSA, containing by far the larger proportion, as well as the most highly organised forms of the class, are again distributed into four sections. 1. PODOPTHALMIA, in which the eyes are mounted upon footstalks, and are moveable. These have almost always branchiæ, properly so called; their feet are partly ambulatory, partly prehensile; and the thorax is covered with a *carapace* or shield (like the upper shell of the turtles), which is formed by the great development of one of the rings, overlapping the rest. 2. EDRIOPHTHALMIA, in which the eyes are *sessile*, or not mounted on a pedicle. The branchiæ are not separate organs, being united with the extremities; these are almost always seven on each side, and adapted for walking. There is no carapace. 3. BRANCHIOPODA, in which there are no gills, but the anterior pairs of legs are flattened into plates, which are subservient to respiration. 4. ENTOMOSTRACA, in which there are no branchiæ, or any apparent organs to supply their place. The eyes are sessile, and commonly united into a single mass. These groups are again subdivided into nine orders, as follows:—

1. The Podophtthalmia consist of the DECAPODA, in which there are five pairs of thoracic extremities, and which have the gills enclosed in a special respiratory cavity; and the STOMAPODA, which have six or eight pairs of thoracic extremities and external branchiæ.

2. The Edriophtthalmia contain three orders—the AMPHIPODA, in which the thoracic members are subservient to respiration, and the abdomen well developed, and furnished with six pairs of limbs; the LÆMODIPODA, in which the abdomen is not developed; and the ISOPODA, in which the abdomen is well developed, and its members, which are similar in form to the rest, subservient to respiration. It is this order which most resembles the Myriapoda.

3. The Branchiopoda contain two orders—of which one, the CLADOCERA, has a carapace in the form of a bivalve shell, with five pairs of thoracic members; whilst in the other, the PHYLLOPODA, there is no carapace, and the extremities, which are formed for swimming, are more numerous, varying from eight to twenty-two.

4. The Entomostraca are also divided into two orders; the COPEPODA, which have the body divided into distinct rings, but without carapace, and the appendages to the mouth in considerable numbers; and the OSTRAPODA,

in which the body is without annular divisions, and entirely enclosed under a large shield having the form of a bivalve shell, the extremities being in very small number. In some members of this division we find a very close approximation to the higher Rotifera.

Order I.—Decapoda.

It is in this order that we find the highest general organisation, the largest size, and the most varied habits; it is the one most useful to man, and most interesting to the naturalist. The lobsters, crabs, crayfish, prawns, shrimps—in fact, nearly all the species that are ever used as food—belong to it. Their growth is slow, but they ordinarily live a long time. Their habits are mostly aquatic; but none of them are killed at once by being withdrawn from the water; and some of them pass the greatest part of their lives in air. They are naturally voracious and carnivorous; the first pair of legs is usually transformed into a pair of powerful claws, by which they seize their food, and convey it to the mouth. This order contains three families; the BRACHYOURA, or short-tailed Decapods, to which the name of *Crabs* is commonly given; the MACROURA, or long-tailed, such as the Lobster, Cray-Fish, &c.; and the ANOMOURA, in which the abdomen is prolonged, but destitute of a shell, so that the tail is soft, and which inhabit the shells of Mollusca, in which they seek protection.

As illustrations of the structure and habits of the BRACHYOURA, the common *Crabs* will suffice; but a peculiar tribe, that of the *Land-Crabs*, should be specially mentioned. These often live at a considerable distance from the sea, and even burrow under ground. Their gills are kept moist by a kind of spongy structure in the interior of the cavity which encloses them; and from this a sufficient amount of fluid is secreted, to prevent them from being dried up. Some species, though living on land, are confined to damp situations. Others, however, ordinarily inhabit elevated regions, and migrate towards the sea once a-year to deposit their spawn.

The MACROURA are distinguished, not only by the length of their tail, but by having it expanded at the extremity into a pair of fin-like processes, which afford valuable assistance in swimming. This family is a very extensive one, and contains the largest species of the whole class.

The Decapods of the family ANOMOURA are commonly known by the name of Hermit-Crabs, from their remarkable habit of seeking protection in the empty shells of molluscs. The shells they seem to prefer for this purpose are those belonging to the family Trochoidea. The abdomen or tail is inserted into the upper part of the cavity, of which, after a time, it assumes the perfect form, so that when withdrawn it presents all the markings of it. The thorax and head occupy the lower part of the spire; and the mouth is closed by one of the claws, which is usually larger than the other, and serves as an operculum when the animal is withdrawn. When they outgrow the habitations they have selected, they quit them and go in search of others; and they try one shell after another, by slipping the tail into it, until they have found one whose size and form suit them.

Order II.—Stomatopoda.

This is a much less extensive order; and the species it contains are entirely marine, and mostly confined to tropical climates; on which account comparatively little is known of them. Some of them have powerful claws,

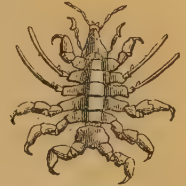

which they use for seizing their prey in the same manner as the Orthoptera among insects; so that these have received the name of Sea Mantes. The accompanying figure shows one of the most characteristic forms of the order, which is abundant in the Mediterranean. The gills are there seen to be affixed, in separate tufts, to the abdominal appendages.

Order III.—Amphipoda.

This is an extensive order, in regard both to the number of species contained in it, and the amount of individuals which are sometimes seen collected together. The greater number of them are marine, but some are found in brooks and reservoirs; all, however, are more or less aquatic in their habits. They are of small size, and swim and leap with agility. The best-known British species is the *Sand-hopper*, which burrows in the sand, and which, unlike the greater part of the order, seldom enters the water.

Order IV.—Lamodipoda.

Of this small order, one of the most interesting and characteristic species is the *Cyamus*, commonly called the Whale-Louse, from its infesting the Cetacea as a parasite. Sometimes these creatures are so abundant on the surface of whales, that the individuals they infest may be recognised at a distance by the white colour these parasites impart to them.

Cyamus Balanarum.

Order V.—Isopoda.

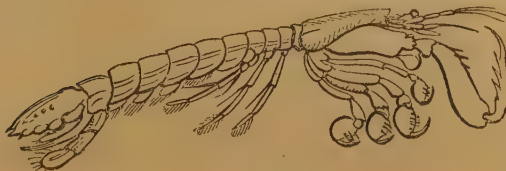

These Crustacea not only resemble Myriapoda in external form, but in many parts of their internal structure. The greater number live in water, but many species, such as the common Wood-Louse, are inhabitants of the land. Having no special apparatus, however, for keeping the respiratory surface moist, they can only exist in damp places. The *Oniscus*, or Wood-Louse, frequents dark and concealed places, such as cellars, caves, chinks in walls, or hollows under stones. It feeds upon decaying vegetable and animal matter, and only comes forth from its retreat in damp weather. It has the power of rolling itself completely into a ball.

Order VI.—Cladocera.

The Crustacea composing this and the three following orders are of very small size, so that the details of their structure can only be examined with the microscope. They mostly inhabit fresh waters, and are in almost constant motion. A characteristic example of this order is the common *Daphnia Pulex*, or Water-Flea, which may be found during the summer in almost every pond, and is recognised by its very rapid and sudden movements, resembling the leaps of the animal after which it is named. These are principally executed by a pair of large branched antennæ, which serve as oars.

Order VII.—Phyllopoda.

To this order, which is characterised by the prolonged form of the body, and the flattening of the extremities which adapts them for swimming, belongs a large number of species, whose movements are generally very regular and equable. The *Branchipus*, one of the most

Squilla Mantis.

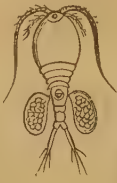

Branchipus Stagnalis.

characteristic examples, is found, often in great numbers, in small puddles, and most abundantly after heavy rain. The eggs are capable of being dried up without injury, and are hatched soon after being moistened.

Order VIII.—Copepoda.

The animals of this and the next order are commonly termed *monoculous*, from the two eyes being united into one mass. In their general habits they agree with the former. The *Cyclops* is an interesting species, very common in the ponds and ditches of this country. The female has an oval sac on each side of the tail, in which the eggs are carried. She is able to produce ten broods in the course of three months, and as these are speedily able to reproduce themselves, it has been calculated that in a year, 4,442,189,120 young may be the progeny of one individual. The majority of the animals of this order swim with the back downwards, darting about with great agility, and moving backwards or forwards with equal ease. In the absence of animal matter, on which they usually feed, they attack vegetable substances.

Order IX.—Ostrapoda.

In habit and general character, the animals of this order, of which the common *Cypris* of our ponds is an example, closely resemble those of the last, but their bodies are enveloped in a sort of bivalve shell. They swim, like the *Daphnia*, by means of the prolonged antennæ, which spread at their extremities into tufts of filaments.

The animals of the division EDENTATA are nearly all parasitic. In their general organisation they are the most imperfect of all Crustacea, some of them approaching the higher Entozoa, whilst others have a resemblance to the lowest Arachnida. The various species of these orders, which need not be more minutely particularised, infest, more or less, almost all marine animals.

There now only remains the remarkable order *Xyphosura*, separated from all the rest by the absence of any special organs for conveying food into the mouth. It receives its name from the sword-like prolongation of the carapace, which is used as a weapon by the natives of the regions in which the animals exist. The *Limuli*, or King-Crabs as they are commonly termed, are peculiar to the East Indies (abounding in the neighbourhood of the Molluccas) and the coast of America. They sometimes attain the length of two feet. Their legs are very short, not extending beyond the margin of the shell. The anterior ones seem to assist in conveying food to the mouth; and the posterior are modified for respiration.

Near the *Limuli* should probably be placed the remarkable group of *Trilobites*, which are at present only

Limulus Polyphemus.

Asaphus Expansus.

Same rolled up.

known in a fossil state, but which were very abundant in former epochs of the earth's history. There can be no doubt, from the character of the animals with whose remains it is found, that the Trilobite was an inhabitant

of the water; and as its integument was evidently hard and articulated, it must have been a Crustaceous animal.

CLASS IX.—MYRIAPODA.

The class Myriapoda is the lowest in which we meet with articulated members, or distinct jointed legs, as well as with an articulated body. These are intermediate in their conformation between the more highly organised legs of insects and the simple bristle-like appendages possessed by some of the Annelida; and this is exactly the place to which we should refer the animals of this class, from a regard to their general structure. For, on looking at the form of their bodies, we observe that they are distinguished by an uniformity in the character of the segments, nearly as great as that which prevails in the Annelida; so that an *Iulus* might almost be likened to an earthworm provided with a stiffened integument, and with slender legs: whilst, on the other hand, the adaptation of the respiratory organs to breathe air with regularity and energy, the increasing complexity of the apparatus of mastication, the possession of distinct eyes, and many other characters, indicate their affinity with Insects—in which class, indeed, some naturalists comprehend them.

Most persons are familiar with the common forms of this class—the *Centipedes* (hundred legs) and the *Millepedes* (thousand legs); and a minute description of them is therefore unnecessary. On examining any of these animals, the following points will be observed. The covering of the body is firm, and of a somewhat horny character, resembling that of many insects. The division into segments is very distinct; a flexible membrane being interposed between each pair of firm rings or plates. This is obviously required by the condensation of the skin; since, if it were otherwise, the body would not have the power of bending in any direction. The legs are covered by the same kind of integument, and are jointed in a similar manner; each terminates in a single claw or hook. No division of the body into distinct regions, like those which are so evident in the true Insects, can be observed; but, on the contrary, the segments are nearly equal along its whole length, and each is provided with one or two pairs of legs. The first segment, or head, is furnished with eyes formed upon the same general plan as those of insects; and also with a pair of long jointed antennæ, which are probably organs of touch. On the side or under surface of the animal may be seen a row of minute pores, a pair usually existing on each segment, which are the apertures for the admission of air to the respiratory organs. The different parts of the nervous system are repeated in a similar manner, a pair of ganglia being found in every division of the body.

The Myriapoda may be divided into two orders, the *IULIDÆ*, or *Millepedes*, and the *SCOLOPENDRIDÆ*, or *Centipedes*.

Order I.—Iulidæ.

The Iulidæ, consisting of animals bearing a general resemblance to the *Iulus*, or common Millepede, are the most nearly allied to the Annelida, both in external form and in the arrangement of the several organs. The *Iulus Terrestris*, or Gallyworm, is a species often found concealed under stones, or beneath the bark of decaying timber. Its body is long and cylindrical, and is composed of between forty and fifty hard rings, which, except at the head and tail, differ but little from one another. Each segment gives origin to two pairs of small legs, which arise close to the middle line along the under surface of the body. These are scarcely large or strong enough to support its weight, so that the animal moves but slowly, and seems rather to glide or crawl than to walk. When at rest, the body is rolled up in a spiral form, and

Iulus.

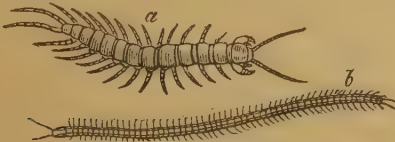

the feet, being concealed in the concavity of the spire, are protected from injury, whilst the firmness of the rings of the body enables them to resist considerable pressure.

The mouth of the *Iulidæ* is furnished with a pair of stout horny jaws, moving horizontally, and furnished with sharp toothed edges; and by means of these, they are enabled to divide with facility the portions of decaying vegetable matter upon which they usually feed. These animals are very harmless to man, not being possessed of any poisonous organs; and they may be regarded as positively benefiting him, by the removal of substances the decay of which would be noxious. The common *Iulus* of this country seldom much exceeds an inch in length, but there is a South American species (*I. maximus*) which attains the length of seven inches.

Order II.—Scolopendridæ.

The animals composing the order Scolopendridæ may be distinguished from the Iulidæ by the greater development of the legs, by the diminution in their number and in that of the segments, and by the flattened form of the body.

Of the carnivorous propensities of the Scolopendridæ, the structure of the mouth affords sufficient evidence. It is provided not only with a pair of horny jaws resembling those of insects, but with a pair of strong sharp claws, formed by an enlargement of the second pair of legs, which are perforated at the tip with a minute aperture through which a venomous fluid is probably instilled into the wounds made by them. Small insects seized in these claws are seen to die very speedily, and in warm countries the bite of the large species of Centipede is a source of great irritation to man, being reputed more injurious than that of the Scorpion, though it is seldom fatal. The application of ammonia is the most effectual remedy for the pain, as well as for the constitutional effects of the bite. The last pair of legs undergoes some modification in this order; being directed backwards, so as to form a kind of double tail; and not being used for walking except when the animal is moving backwards.

a, *Lithobius Forficatus*; b, *Geophilus Longicornis*.

The European species of this order seldom exceed two or three inches in length, but they present themselves by no means unfrequently. Like the Iulidæ, they frequent dark places, hiding themselves under stones, the bark of trees, in the ground, and especially in over-ripe fruit which is likely to attract insects. In tropical climates, however, they attain a much larger size, and abound still more. Centipedes of the length of fifteen inches have been brought to this country; and it is stated by Ulloa, that at Carthage they have been seen exceeding a yard in length and five inches in breadth; and that the bite of these is mortal. It is doubtful, however, whether this statement may be relied on.

CLASS X.—ANNELIDA.

The class of Annelida is the lowest in which the articulated structure is distinctly manifest. It is composed of animals having a worm-like body, without true jointed legs; and marked by transverse lines that divide it into a succession of rings or segments, which, except the first and last, differ little from each other but in size. Many of them are remarkable for the red colour of their blood; and, on account of this character, they have been regarded as approaching nearer to the vertebrated sub-kingdom than any other class of articulated animals. This is not universally observed,

however, for in some species the blood has a greenish tint, and in others it is nearly colourless, as in invertebrata in general. The body is usually soft and flexible, the rings being possessed of little firmness, and no internal skeleton of any description being present. It is not only flexible, but capable of great alteration in its dimensions, as may be seen in the common earth-worm or leech.

The greater part of this class are solely inhabitants of the water, and are provided with external appendages for exposing the blood to its influence, which are analogous in function to the gills of fishes, but which are often distributed over the whole surface, and are also concerned in locomotion. It may be regarded as the regular form of these animals to possess such appendages upon every segment. But not unfrequently the body is enclosed in a tube, and then the gill-tufts are collected in the neighbourhood of the head, where they may be protruded from its opening. The earth-worm and a few other species are adapted to live on land, and they have a series of air-sacs arranged along the interior of the body on each side, opening externally by a small orifice, of which a pair may be seen upon each segment.

The first segment, which may be termed the head, contains the mouth, sometimes provided with a formidable apparatus of jaws; and it is also generally furnished with eyes, and with variously shaped tentacula, which are apparently instruments of touch. The last segment is occasionally destitute of the appendages with which the rest are provided, and these are replaced by a sucker, which is of great assistance in locomotion.

The class is subdivided into orders by the differences in general conformation and habits exhibited by the tribes which compose it; and especially by the character and distribution of the respiratory organs. The first order, DORSIBRANCHIATA, includes those which have the branchial appendages or gill-tufts disposed regularly along the body, sometimes extending its entire length, and sometimes restricted to the segments about the middle. This order has been also denominated *Errantia*, from the active habits of the animals comprehended in it. In the next, TUBICOLA, we find worm-like animals inhabiting fixed and permanent residences like the Mollusca. Sometimes they are enclosed in shelly tubes, formed by an exudation from their own surface, and sometimes in casings constructed by the agglutination of foreign substances. The disposition of the gill-tufts around the head is the principal character which distinguishes the animals themselves from those of the first order. In the third order, TERRICOLA, the body is destitute of all external appendages, except some minute and almost imperceptible bristles; for the respiratory organs are here developed internally, the animals being formed to crawl upon the ground instead of swimming through the water. And in the last, SUCTORIA, the body is destitute even of these bristles, but is furnished with a sucker at each end of the body. The two latter groups were regarded by Cuvier as forming one order.

Order 1.—Dorsibranchiata.

Of the foregoing orders, the Dorsibranchiata appear, on the whole, to possess the most complex structure, as well as the most varied faculties, and they also exhibit the most characteristic forms of the class. The head is almost always distinct from the body, and furnished with highly-developed organs of sensation, as well as with complex instruments of mastication. These marine worms do not attain any considerable dimension upon our own coasts, rarely exceeding a few inches in length; but in tropical climates some species are found of comparatively gigantic proportions, having their bodies composed of 400 or 500 segments, and occasionally measuring four feet from one end to the other. Their general form will be seen in the accompanying figure, which represents the *Syllis Monilaris*; and the enlarged view of one of the lateral appendages will show the parts of which it consists. In the centre there is a tuft of delicate bristles, which may be regarded as the chief

Syllis Monilaris, with an enlarged representation of one of its appendages.

organ of respiration, the blood being sent into them to be exposed to the air contained in the water ; above and below there are separate bristles, much more elongated, of which the lower one has a jointed character ; these are instruments of locomotion, and may be regarded as rudimentary legs. The arrangement of these parts differs much, however, in the various tribes of this order.

Among the more interesting forms of this order may be mentioned the family NEREIDÆ, or Sea-Centipedes, of which many species inhabit our own coasts, but much larger ones are found in tropical seas. They have no venomous power, but are extremely voracious ; and are often furnished with a complex apparatus for seizing their prey and reducing it to fragments.

The *Aphrodita* is an animal well known on our coasts under the name of *Sea-Mouse* ; numbers are often cast up by a gale of wind. The body is flattened, and shorter and broader than that of other Annelida. The back is covered by two longitudinal ranges of broad membranous scales, under which the gills lie concealed. The most common species of *Sea-Mouse* are about six or eight inches long, and two or three broad. A great part of the body is covered by bristles of brilliant lustre, and of colours which vary with the light ; so that the animal is scarcely surpassed in beauty of colouring by any other. The *Arenicola piscatorum*, known to fishermen by the name of *Lob-worm*, is another species common on our coasts, and is eagerly sought as a bait. It burrows, like the earth-worm, in the sand ; and the place of its excavations may be known by the little heaps which it casts up. The branchial tufts are confined to the centre of the body, where they form on each side a series of bunches, which are remarkable, during the life of the creature, for their beautiful red colour, derived from the crimson blood which circulates copiously through them.

Order II.—Tubicolæ.

Comparatively little is known of the structure of the animals of the order Tubicolæ, which never attain to such great dimensions, and do not offer to the naturalist the same facilities for examination. The structure of the casings which they form, however, has been fully investigated. One of the commonest of these is the shelly tube exuded by the *Serpula*. This is formed of calcareous matter resembling that of the shells of Mollusca, and apparently secreted from the surface of the body in a similar manner. These tubes, which are often very greatly contorted in form, are generally found encrusting the surface of stones or other bodies which have been immersed for any length of time at the bottom of the sea ; they are closed at one end, which *Serpula Contortuplicata*, taken out of its tube, is open.

The animal forming this shell has its branchial filaments all assembled round the head, where they form a pair of most elegant fan-like appendages, which usually possess very brilliant colours. At the base of each tuft is a fleshy filament ; and one of these, on the right or left side indifferently, is always prolonged and dilated at its extremity into a flat disk, which fits to the mouth of

the shell, and serves to close it when the animal is withdrawn into the tube.

The *Sabella* is an animal very much resembling the *Serpula* ; but it constructs its tube by agglutinating particles of clay or fine sand. The *Terebella* forms a similar tube, by cementing together minute shells and fragments of larger ones, together with particles of sand, gravel, &c. ; and some species live in aggregate groups, so that the clustering together of their tubes forms solid masses, which may go on increasing to a considerable size. In none of these cases is the shell or tube to be regarded as part of the animal ; it is merely its habitation. The Annelide forms no muscular attachment to it, and its body can be easily drawn forth from its interior.

Order III.—Terricolæ.

The order Terricola includes very few genera, of which the *Lumbricus*, or common *Earth-worm*, is the chief. They live in general beneath the surface of the ground, either perforating the dry soil, or burying themselves in mud, where many of them lead a semi-aquatic life. When the *Earth-worm* is boring, it insinuates its pointed head between the particles of earth, amongst which it penetrates like a wedge ; and in this position, the anterior part of the body is fixed by spines or bristles curved backwards, which prevent it from slipping. The hinder parts are then drawn forwards by a longitudinal contraction of the whole animal—a movement which the spines do not oppose. This swells out the anterior segments, and forcibly dilates the passage into which the head had been already thrust. The spines upon the hinder rings then take a firm hold upon the side of the hole thus formed, and prevent any backward movement ; the head is again forced forward ; and, by a repetition of the process, the animal easily makes its way through substances which it would at first have seemed impossible for it to penetrate.

The burrowing of *Earth-worms* is a process exceedingly useful to the gardener and the agriculturist ; and these animals are far more beneficial to man in this way than injurious by devouring the vegetables set in the soil. They give a kind of under-tillage to the land, performing the same below ground that the spade does above for the garden, and the plough for arable land, and loosening the earth so as to render it permeable to air and water. It has lately been shown that they will even add to the depth of the soil, and create mould where none existed before. This they do principally by the exercise of their digestive process. They take a large quantity of the soil through which they burrow into their intestinal canal ; from this they extract the greater part of the decaying vegetable matter it may contain, and reject the rest in a finely divided state, forming what are known as worm-casts. By the accumulation of these, a field which was manured with marl has been covered in the course of eighty years with a bed of earth averaging thirteen inches in thickness.

It is commonly supposed that the *Earth-worm* may be multiplied by the division of its body into two pieces, of which each will continue to live. This does not appear to be the case. If it be divided across the middle when in motion, each will continue to move for a time ; but only the piece which bears the head will be found alive after a few hours. This forms a new tail, and soon shows little sign of the injury. But if the division be made near the head, the body will remain alive, and will renew the head ; and the head with its few attached segments will die. The *Naidæ*, however, have a much greater amount of reproductive power ; for they may be cut into many pieces, of which each will become a perfect animal ; and it is stated that a separation takes place spontaneously, but to a much greater extent.

Order IV.—Suctorii.

The order Suctorii contains the common Leech and its allies, which are all animals of aquatic habits, but

not all agreeing in its blood-seeking propensities. Most of the tribe, however, live at the expense of some other animal.

The structure of the mouth of the leech is very interesting. It is situated in the middle of the cavity of the anterior sucker; and three little cartilaginous

Leech, with the anterior sucker and teeth enlarged.

bodies, usually called *teeth*, but more properly *jaws*, are seen to be disposed around it, in such a manner that the three edges form three radii of a circle. Each of these has two rows of very minute teeth at its edge; so that it resembles a small semicircular saw. It is imbedded at its base in a bed of muscle, by the action of which it is worked in such a manner as to cut into the skin—a sawing movement being given to each piece separately. It is in this manner that the tri-radiate form of the leech-bite is occasioned; each ray being produced by a separate little saw. The lacerated character of the wound is very favourable to the flow of blood, which is further promoted by the vacuum created by the sucker. The greater number of the *Leech* tribe are inhabitants of fresh water; some, however, are only found in the sea; and there is one terrestrial species, a native of Ceylon, which appears to be more voracious than any other, and to be one of the greatest pests of that fine island.

CLASS XL.—CIRRHOPODA.

The animals composing this class have so many characters in common with the Mollusca, that they have been generally regarded as belonging to that sub-kingdom. The body and its appendages are themselves quite soft; and the skin has the loose spongy muscular character which corresponds with the *mantle* of Molluscs. From its surface is secreted a shell, composed of several pieces, but not differing in general aspect from multivalve shells belonging to that division. Further, the shells are either themselves firmly united at their base to some solid masses, or they are attached by a foot-stalk; so that the conditions in which the animals exist closely resemble those to which we observe the Mollusca peculiarly adapted.

On the other hand, when we examine the animal itself, we find that it is perfectly symmetrical in its form—a character nowhere existing among the Mollusca which are enclosed in shells. Its body is prolonged, and exhibits a tendency to division into segments; and from each of these there arises a pair of appendages on each side, which possess something of a jointed structure. These *cirri*, as they are termed, are long tapering arms, fringed with cilia, or little hair-like filaments; and they have gills at their base. Further, the mouth is furnished with lateral jaws, which no Mollusca possess; and the nervous system consists of a double cord, with a pair of ganglia in each segment of the body, precisely as in the other Articulata. The most interesting proof, however, that the Cirrhopoda belong to this division, is derived from the history of their development. On their liberation from the egg, they present a form much more analogous to that of the lower Crustacea than to that of the adult animal, which they only acquire after a series of metamorphoses. They are furnished with antennæ and eyes, and move freely through the water; but when they become fixed they lose also these organs of sense. The shell is not formed of simple layers, like that of the Mollusca, but is traversed by a

complex series of canals, through which nourishment is conveyed to it.

The Cirrhopoda are divided into two principal groups—the *pedunculated* and the *sessile*. The latter, of which the common *Balanus* or *Acorn-shell* is an example, have the base of the shell fixed immediately to rocks. In the former, such as the well-known *Barnacle*, the shell is attached by a peduncle or footstalk, which consists of a tube of leathery consistence, and is often of considerable length. In both groups, the animals, not being able to go in search of food, obtain it through the currents produced by the action of their cilia.

The shell of the common *Barnacle* consists of five pieces, of which two are large valves, somewhat resembling those of a mussel; two smaller pieces are jointed to these near the point; and one unites the valves along the back edge. These cover the whole of the mantle. Barnacles are abundant in all seas, and fix themselves, in preference, to wood; so that a piece of timber which has been for a short time floating in the ocean is almost sure to be partly covered with them; and ships' bottoms, if not protected by copper, are rendered so foul as greatly to impede their sailing.

Group of Anatifæ, attached to a ship's bottom.

The *Balanus*, or *Acorn-shell*, has more of a globular shape, with a narrow mouth, and is composed of a certain number (varying in the different species) of plates, of a triangular form, so disposed, that an addition to the edges of each shall preserve the general proportions of the shell, whilst increasing its cavity in all its dimensions in accordance with the growth of the animal. In this arrangement we recognise the same plan as that adopted in the shell of the echinus. The animal closely resembles the barnacle. The mouth of the shell is guarded by an *operculum*, consisting of two or more valves, which close it more or less completely. The rocks, piers, &c., on many parts of the coast, are covered with these animals; and small species of them also attach themselves to shells of various kinds.

CLASS XII.—ROTIFERA.

The class Rotifera is one composed entirely of animalcules which can only be distinctly seen with the microscope; and it takes its name from the wheel-like organs with which most of them are provided, whence they are commonly known as *Wheel-Animalcules*. It is only within a very recent period that the complex structure of these beings has been understood, and that they have been separated from the animalcules of simpler organisation. It is on account of the prolonged

form of their bodies, the position of the mouth and eyes at one extremity, the occasional marking of transverse lines indicating a division into segments, and most of all by the character of the nervous system, when that can be detected, that the Rotifera are ranked in the articulated sub-kingdom. Unquestionably, they bear more general analogy to that than to any other; but they must not be considered as characteristic specimens of it.

The structure of the common wheel-animalcule, *Rotifer vulgaris*—which may be found in many collections of stagnant water, especially such as have been long and freely exposed to the atmosphere—will afford a good illustration of that of the class. The body exhibits a prolonged form when fully extended; but, as the integument is very elastic, it may be drawn up into a circle or made to assume a great variety of shapes. At one end it is furnished with a pair of projections, which are surmounted by circular fringes of cilia. It is by the vibration of these cilia that the currents are produced in the water around, which give an appearance as of the continual revolution of wheels. Between the wheels a sort of head extends forwards, on which a couple of red spots may be observed, which are believed to be eyes. The mouth is situated at the base of this central projection. At the opposite end the body is prolonged into a sort of tail, furnished with three prongs; and by this the animal fixes itself when working its wheels for obtaining food.

The delicate membrane which covers the body has two series of muscular fibres disposed within it; one set running longitudinally from end to end; the other transversely, so as to form rings around the body. By the contraction of the former the body is shortened; by that of the latter its diameter is decreased, and it is consequently lengthened. This is the same kind of apparatus as that by which the form of the leech and worm tribe is altered. The transparency of the integument allows the contained organs to be distinctly seen; and these are perceived to have regular membranous walls of their own, and to be altogether distinct from the general substance of the body. The most curious of these is the gizzard, or set of jaws (as it may perhaps be termed) in which the food is ground down before it is transmitted to the true stomach. This is placed in the fore part of the body, and principally consists of a hard framework in two pieces, each of which bears two teeth. The two frames are moved by powerful muscles, and worked in such a manner that the teeth are made to interlock and to separate alternately, so as to tear all the food which is transmitted into the stomach. From the stomach there passes backwards a long straight intestine, which terminates near the posterior part of the body.

These animalcules feed chiefly upon others of smaller size and simpler character. The currents set in motion by the cilia are very powerful, and draw in whatever small bodies are within their scope; and the animal seems to select from these what is adapted to afford it nutrition. Sometimes it folds in its wheels, and moves along a solid surface by the suckers with which its head and tail are furnished, in the same manner as a leech; and sometimes it remains altogether inert for a considerable period. One of the most remarkable points in its history is its power of being revived by the application of moisture, after having been entirely dried up. This experiment, however, does not always succeed.

The Wheel-Animalcules are propagated by eggs, the development of which within the body of the parent may be very distinctly seen, on account of the transparency of the latter. These eggs are large and not very numerous, seldom more than four; but they rapidly arrive at maturity, and are soon capable of producing others. It has been calculated that, from a single individual, more than a million may be produced in ten days. In some of this class, the eggs are borne for some time on the outside of the body, attached to its posterior part, as in the *Cyclops* and other minute Crustacea, to which the general structure of the higher species of

Rotifera shows them to be nearly allied. Other species connect this class with the higher Polypifera.

CLASS XIII.—ENTOZOA.

This class derives its name from the peculiar condition in which the animals composing it exist, most of them being inhabitants, during their whole lives, of the bodies of other animals, generally those of higher organisation, from the juices of which they derive their nourishment. Many of them possess a distinct worm-like form, the body being much prolonged, and exhibiting a division into segments, and the mouth being situated at one extremity. These, therefore, evidently belong to the Articulated series. There are others which, in the absence of all distinct organs, and also in the circularity of their form, seem to approximate more to the Radiata. Some species, formerly located in this class, are now known to be low kinds of Crustacea.

A division of the Entozoa into two sections has been proposed, founded upon the general peculiarities of their structure, which it may be useful here to adopt. In the first and highest of these, there is a distinct intestinal tube, with an orifice at each end; and traces of a nervous and muscular system, more or less developed, may be detected. This division evidently approximates to the Annelida. It includes, among many other species, the *Filaria*, or Guinea-Worm, which burrows in the flesh of man and other animals in warm climates; if undisturbed, it will often continue its operations for a considerable time without much uneasiness; but, if disturbed, it sometimes occasions the most excruciating pain. When it shows itself externally, it is extracted very slowly, for fear of breaking it, in which case the remainder would retreat, and continue to exist; it grows to the length of several yards. The *Ascaris lumbricoides*, or Round Worm of the intestines, also belongs to this group. It infests not only man but many of the lower animals, and often occasions severe disease and even death. It derives its second or specific name from its resemblance to the earth-worm. The short active Thread-worms, sometimes infesting the lower part of the intestine, are another species of the same genus.

In the lower division of the class, there is no distinct alimentary canal; the cavities for the reception of food, as well as those for other purposes, being, as it were, channelled out of the soft, almost homogeneous, tissues of the body. Some of these still preserve the worm-like form. Such are the so-called eels in vinegar; and the curious little parasites which have been recently discovered to infest the muscles of man. To this group also belongs the *Tænia Solium*, or Tape-Worm, in which we find a remarkable repetition of organs. The body is distinctly divided into joints or segments, which sometimes amount to several hundred, the whole animal occasionally attaining the length of ten feet. These segments are all connected by the nutritive canal, which runs from one end to the other; but the reproductive apparatus is repeated in each division. The head is small, and possesses four mouths, surrounded by a double circle of small hooks. Its existence is essential to the life of the body, the latter dying if it be broken off; but if some of the joints remain attached to the head, it continues to grow and form new ones. In this repetition of parts, we see a tendency towards the type of the Polypifera.

One of the most simple of all the Entozoa is the common *Hydatid*, or Acephalocyst (headless bag), which seems to consist of nothing but a globular membranous bag filled with a limpid colourless fluid. It exhibits no motion or indication of sensation, when stimuli of any kind are applied to it; and it is often difficult to distinguish it from the tissues in which it is found. Its power of reproduction, however, by the formation of *gemmæ*, or buds between its layers, shows it to be entitled to the rank of an independent being; the young Hydatids are thrown off internally or externally according to the species.

Amongst the animals associated with this group, though not conforming with it in their residence, is the *Planaria*, a very interesting genus, of which some species inhabit fresh water and others are marine. The body is flat, and three or four times as long as broad. Within its soft tissue are channelled out not only a complex digestive cavity, but also a system of vessels which absorb fluid from its walls and convey it through the system, and a reproductive apparatus. The stomach opens, not by a mouth at one end, but by a sort of sucker projecting from the middle of the body; and through this the *Planaria* imbibes the juices of various aquatic animals which it attacks, mastering even active little worms by twisting its body round them. The most curious part of their economy consists in their power of reproducing parts that have been lost, and of repairing injuries, which seems almost as great as that of the *Hydra* among Polypes. They may be divided into three parts, of which the former shall contain the two minute spots which are believed to be eyes, the middle one the sucker, and the posterior one the reproductive apparatus; and in a short time, each part will develop itself into a new individual, perfect in all its parts. It may be partially split longitudinally from either extremity, so that two heads or two tails will be formed, uniting at the middle point, but each being complete in itself.

SUB-KINGDOM—MOLLUSCA.

The range of animal forms comprehended in this division of the Animal Kingdom is so great, that it would be difficult to include them by any definition applicable to them all. The highest class approaches Fishes in many points of its organisation; whilst in the lowest we not only lose sight of some of the characteristic peculiarities of the group, but we find a near approximation to the higher Polypifera. In all the Mollusca, the body itself is of soft consistence, as its name imports, and is enclosed in a soft elastic skin, lined with muscular fibres, which is termed the *mantle*. This skin, in many instances, is not applied closely to the body, but forms a membranous bag, having apertures (which are sometimes prolonged into tubes) for the entrance and egress of water; and through these the respiratory organs, which are situated within the cavity, are regularly supplied with the pure fluid necessary for aerating their blood; and the mouth, when it is not capable of being projected beyond this cavity, is supplied with food by the same stream.

The Mollusca possess in general a very complicated digestive and circulating apparatus; but the organs of sensation and voluntary motion are comparatively undeveloped. The great bulk of their bodies is made up of the stomach and intestines, the liver and other glands connected with the alimentary canal, the respiratory apparatus, and the ovary for the production of germs (which is usually very large); and the muscular system, which in the *Articulata* forms so large a proportion of the whole structure, is here frequently reduced to a few scattered fibres, and in but few instances attains any complexity and power. A considerable number of Mollusca are formed for an existence as completely stationary as that of the *Zoophytes*, and are dependent for their nourishment on the supplies of food casually brought within their reach by the waves and currents of the ocean. A few, however, have powers of locomotion which enable them to search actively for it themselves; but the greater number wander sluggishly, like the snail, from place to place, devouring with voracity such supplies as they meet with, and being capable of fasting for long intervals when none come in their way.

It is from the surface of the mantle that the calcareous matter is exuded which forms the shell, in those species which possess such a protection; its particles are held together by a sort of glue, which exists in much larger

proportion in some species than in others. In very hard and brittle shells, if the calcareous matter be removed by the action of an acid, the animal matter that remains appears in the form of separate flakes. But in many other shells thus treated, the animal portion retains its form after the removal of the lime; and there are a few in which the (so-called) shell consists only of a substance like horn, without any intermixture of calcareous particles. Such a substance appears to be formed by the young animal before the true shell is secreted; and it is also the first that appears when the animal is repairing the effects of an injury to the old one. It is this that constitutes what is commonly termed the *epidermis* of shells—a covering possessed in their natural state by all that are not enveloped in a fold of the mantle, but which is commonly removed when the shell is preserved, as it impairs the beauty of the exterior. The shell is most solid and massive in those species which lead an inactive life; and is usually light and thin, or altogether deficient, in those whose powers of locomotion are greater. Its thickness often varies greatly amongst different individuals of the same species, according to the roughness or tranquillity of the waters they inhabit.

As the shells of Mollusca are the parts of their structure by which they were best known, it was natural that the first attempts at classification should be founded on their peculiarities. Accordingly, Linnaeus arranged them into *Univalves*, *Bivalves*, and *Multivalves*, according to the number of pieces of which the shell is composed; and this classification, from its simplicity and the apparent facility of its application, has been very generally adopted. But, as will hereafter be seen, it is only within certain narrow limits that the character of the animal can be known by the structure of its shell; and, by the Linnæan classification, animals are brought together which are widely separated, and others are placed in distinct classes which are closely allied. Again, such a classification is totally inapplicable to the very numerous shell-less Mollusca, some of which approach so closely to those bearing shells (as, for example, the *Slug* to the *Snail*), that scarcely any essential difference exists. It is obvious, then, that although the characters derived from the shell may often be valuable in enabling us to recognise the remains of particular animals, classification must not be founded on them, but on the general conformation of the animals by which they are produced.

Following this principle, the Mollusca may be divided, first, into those having a *head*—that is, a prominent part of the body on which the mouth is situated, with organs of sense in its neighbourhood—and those which are *acephalous*, or headless. Among the former we perceive three very distinct types of structure.

The *CEPHALOPODA*, or *Cuttle-Fish* tribe, have feet or tentacula arranged in a circular manner around the head. In this group we find the nearest approximation to the *Vertebrata*.

The *PTEROPODA* constitute a small but interesting class, characterised by the possession of a pair of wing-like expansions of the mantle, and by the great symmetry of their bodies. These expansions serve as fins, by which they swim through the water with great velocity.

The *GASTEROPODA* are the most extensive group of the whole. The two former are confined entirely to the sea; amongst these we find species adapted to live in fresh water, and even on land. They have but one muscular expansion or foot, and this proceeds from the under surface of the body, as may be well seen in the *Snail*.

In each of these orders we observe a considerable variation in regard to the relative size and even the existence of a shell; for whilst there are some species in all of them which are entirely destitute of this protection (such being called *naked Molluscs*), there are others which possess it in a slight degree, having it generally concealed in a fold of the mantle, whilst in others it completely envelops the body, when they

desire to withdraw themselves under its protection. In the different species of Snail and Slug, all agreeing closely in general structure, every variety of this kind may be seen.

In the headless Molluscs, on the other hand, we find two very distinct groups; in the first of which the shell is constantly present, whilst in the second it is as invariably absent. The general structure of the latter is much inferior to that of the shell-bearing class, and it approaches more nearly in several of its characters to the Polypifera.

The highest class of Acephalous Molluscs is named CONCHIFERA, from the constant occurrence of a shell, which is nearly always formed of two pieces, or *bivalve*.

The lowest is denominated TUNICATA, the shell being replaced, as it were, by a leathery or cartilaginous envelope or tunic, which encloses the whole body.

CLASS XIV.—CEPHALOPODA.

The class of Cephalopoda, which is so named from the arrangement of the feet or locomotive organs around the head, must be regarded as the highest among the Mollusca in respect to the complexity of its organisation, and it is the one which approaches most nearly to Vertebrated animals. In the general form of their bodies, and in their adaptation to rapid motion through the water, many species bear a considerable resemblance to Fishes, and are, indeed, commonly reputed as such. The name of the class expresses the character which distinguishes it from all others. On the head, which is furnished with eyes resembling those of higher animals, and also with organs of hearing, and perhaps also of smell, are disposed in a circular manner the curious appendages, which have received the names of *feet* or *arms*, and to which either term may be justly given, as they are organs of prehension as well as of locomotion. These are usually eight or ten in number; but in the true *Nautilus* they are much more numerous, amounting to nearly a hundred.

The mouth, which is situated in the centre of the circle of arms, is provided with a pair of firm horny mandibles or jaws, of which one is sharply pointed, and overlaps the other when closed, so that the whole very much resembles the bill of a parrot. This beak encloses a large fleshy tongue, roughened with horny prickles; and the oesophagus leads to a muscular stomach, which much resembles the gizzard of birds. All the Cephalopoda are aquatic, and consequently breathe by gills. These are disposed symmetrically on the two sides, and are covered in by the mantle. This envelope includes the whole body, but there is an opening in it which gives passage to the head. Through this opening the water enters to the gills, and it is expelled through a tubular prolongation of the mantle termed the *funnel*, which also serves as the excretory canal for other fluids.

Most of the Cephalopoda possess something analogous to the shells of other Mollusca, although it often exists in a form and position which might almost prevent its being recognised as such. The only species at present known in which the body of the animal is enclosed within it, as in the shells of Gasteropoda, are the *Nautilus* and the *Argonauta* (Paper-Nautilus). In the former of these the shell is spiral, and is divided by transverse partitions into chambers, in the last or outermost of which the animal lives; and, when it wishes to enlarge its shell, it prolongs the mouth of it, which widens as it is prolonged, and throws a new partition across the bottom. The shell of the *Argonauta* has no such chambers, and the animal, when hiding within it, occupies the whole of its cavity. In the common *Sepia* (Cuttle-Fish), on the other hand, the shell is reduced to the form of an oval plate, commonly known as the *cuttle-fish bone*, from which pounce is derived, that may be picked up on almost every shore; and this is enclosed within a fold of the mantle, and lies upon the back of the animal. In some of the more slender and flexible species even this is nearly wanting; all that

remains of a shell in the *Loligo* (Squid) being a narrow horny plate, somewhat resembling a feather in shape, whence it is termed the *pen*.

The arms of all the Cephalopoda are covered with very curiously constructed suckers, by which they are enabled to take firm hold of any thing to which they are applied. These act by excluding the air, and thus producing a vacuum, exactly upon the principle of the boy's leather sucker. In this manner they are enabled to master animals which it would have been supposed entirely out of the power of their soft unprotected bodies to combat successfully. They are generally agile as well as voracious; and prey upon almost all other classes of marine animals. Their especial articles of food, however, are Fishes and Crustacea; and they are probably the only animals which are able to restrain the inordinate multiplication of the larger members of the latter class. The firm armour of the crab or lobster, and its powerful claws, are no protection to it against these soft-limbed cuttle-fish, which wind their arms round their bodies, and, fixing every part by means of their suckers, tear apart the divisions of the shell by means of their hard parrot-like bills. So firmly do these suckers adhere, that, while the muscular fibres remain contracted, it is easier to tear away the substance of the limb than to release it from its attachment.

The Cephalopoda which are unprotected by an external shell are furnished with a curious means of escaping from their enemies. This is the secretion of a dark fluid, which, when emitted by the animal, tinges the water around to such a degree that it can escape in the cloud it has made. The fluid is usually stored up in a bag communicating with the funnel, through which it is ejected under the influence of alarm. This ink-bag, as it is termed, is collected from the species inhabiting the Indian seas; the ink forms a valuable pigment, known to the artist as *sepia*, the name of the animal which furnishes it.

The class of Cephalopoda may be subdivided into two orders. In the higher division, which approaches the nearest to vertebrate animals, the *branchiæ* or gills are two in number, and the order is termed DIBRANCHIATA; whilst in the one most closely allied to the Gasteropod Mollusca, the *branchiæ* are four in number, and the order is therefore termed TETRABRANCHIATA.

Order L.—Dibranchiata.

The Dibranchiate order includes all the best-known forms of the class. It is divided into two tribes, in one of which there are but eight arms, whilst in the other there are ten, of which, however, two are different from the rest. The first of these, termed OCTOPODA, may be considered as the highest in point of general organisation; the second, termed DECAPODA, presents many points of approach to the Tetrabranchiate order, both in the increased number of arms, and in the presence of an inner circle of short tentacula, as well as in several internal characters. The *Sepia*, or common Cuttle-Fish, is a characteristic example of the DECAPOD family. Some species of it abound in almost all seas. It has two long slender arms, which are furnished with suckers only at their extremities; and by these the animal is said to fix itself, as by anchors, when exposed to a rough sea or strong current. They are probably employed also in seizing prey, which is brought by them within the range of the others.

To this group we are probably to refer the *Spirula*, a little chambered shell, the animal of which is very imperfectly known; and a large number of fossil chambered shells, known as *Ammonites*, *Belemnites*, &c.; the animal of which was probably analogous to the *Sepia*, including the shell, like the bone of the cuttle-fish, within the body.

The OCTOPODS, which form the highest family of the Dibranchiata, have but eight arms, without tentacula; and they are destitute of lateral fins, so that they depend entirely upon the arms for their movement through the water. Accordingly, it is found that these are very

large and powerful, and that the body is proportionally short. The arms are generally united at their bases into a kind of circular fin, by the motion of which the animal can swim backwards with great energy. The common *Octopus*, or *Poulop*, of European shores, has the arms six times the length of the body, and each furnished with 120 pairs of suckers. It can leave the water, and creep over the beach; taking hold of the ground before it by the extension of its arms, and then dragging the body towards the point at which the suckers are attached.

A very interesting species of the Octopod group is the *Argonauta Argo*, commonly called the *Paper-Nautilus*, from the whiteness and delicacy of its shell. As the animal has little in common with the true *Nautilus*, it would be much better if the latter designation were entirely abandoned, and the term *Argonaut* substituted for it. The shell is not chambered, but possesses one spiral cavity, into which the animal can withdraw itself entirely; this, however, has no muscular attachment to it, whence it has been supposed by many naturalists that it was only a parasitic inhabitant, which had taken up its abode within it, and that the shell, from its resemblance to that of *Carinaria*, was formed by a Gasteropod mollusc allied to that genus. It has been lately proved, however, by the interesting experiments of Madame Power, that the shell increases regularly with the growth of the animal, which possesses the power of repairing it when injured; so that no doubt can exist that the Argonaut is the original constructor of it.

Of the eight arms of the Argonaut, six taper gradually towards the extremities; but two are expanded into wide membranous flaps. From very early times, this animal has been reputed to swim on the surface of the water, using its arms as oars, and spreading these ex-

to nearly a hundred; they are unprovided with suckers; and they are short and slender, resembling closely the tentacula of many Gasteropods.

The head of the *Nautilus* supports a large fleshy disc, upon which it is believed that the animal crawls upon the bottom or sides of the ocean, as a snail upon its foot. The animal frequents deep waters; and, though it is occasionally found at the surface, it sinks upon the least alarm, so that it has been very rarely captured, although the empty shell is so common. This power of rising and falling in the water appears in some degree connected with the structure of the shell, and with the mode in which its chambers communicate with the body by a membranous tube which passes through all the partitions, and is called the *siphuncle*. But of the mode in which this operates no very satisfactory account has yet been given.*

A large number of fossil shells, analogous to that of the *Nautilus*, and hence called *nautilites*, are found in various strata, from the oldest limestones and sandstones of the Silurian system, to those covering the chalk.

CLASS XV.—PTEROPODA.

The Pteropoda are a small but remarkable class of Mollusca, distinguished by the adaptation of their structure for active locomotion in water only. Their general organisation is higher than that of the Gasteropods; and they are particularly distinguished by the possession of a pair of fin-like organs, which are attached to the anterior part of the body, and are evidently adapted for propelling it rapidly through the water. The body is uniformly symmetrical; that is, its two sides precisely correspond—a condition obviously favourable for rapid movement. It is from the wing-like character of these lateral appendages that the name of the class is derived.

The dimensions of the animals composing this class are uniformly small; but the number of individuals which associate together in shoals is often enormous, so that the sea appears literally alive with them. Some of them are possessed of a shell, whilst others are unprovided with such a protection. Wherever it exists it is very light and delicate; and it seldom covers more than the posterior part of the body. In one beautiful little Mollusc, the *Cymbulia*, it is of a slipper form, the wings or fins issuing from the large opening. The head is usually prominent, possessing eyes and sensitive tentacula; and the interior organisation is of very complex nature.

One of the best-known genera of this group is the *Clio*, which abounds both in the arctic and antarctic seas, and is a very important article of food to the whale. The aspect of this animal will convey a good general idea of that of the whole class. The *Clio* is itself eminently carnivorous, and in its whole organisation is fitted to seize and prey upon the yet more minute inhabitants of the deep.

The *Clio Borealis* is well known to the whale-fishers and others as *whale's food*; this species swarms in the

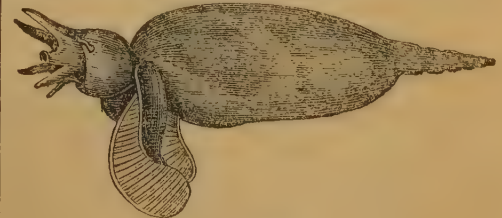

Shell of Argonaut, with animal in the reputed position.

panded membranes as sails to the wind. But it is now known, by accurate observation of the living animal, that this is altogether a fiction (though an interesting one); and that the expanded arms are spread over the sides of the shell, meeting along its keel or edge, and almost completely enclosing it. It is by these, indeed, rather than by the surface of the body itself, that the calcareous secretion is poured out for the enlargement or separation of the shell. By the action of the arms, the Argonaut swims backwards in the same manner as other Octopi; and it can also creep along the bottom of the sea.

Order II.—Tetrabranchiata.

From the remains preserved in a fossil state, the Tetrabranchiata appear to have formerly abounded in our seas; but the only living representative of them is the *Pearly Nautilus* (*N. Pompilius*). In the animal which forms and inhabits the well-known chambered shell found on most tropical shores, we observe many differences from the usual type of organisation in the Cephalopods. The arms are very numerous, amounting

Clio Borealis.

arctic seas, and when the weather is calm, these little animals may be seen floating in myriads upon the sur-

* See Dr Buckland's *Bridgewater Treatise* for an attempt at explanation. This is deficient in its application to all those cases in which the siphuncle is a shelly not a membranous tube, as in the *Spirula*, *Ammonite*, &c

face. According to Cuvier, the sea is sometimes so glutted with them, that the whales cannot open their mouths without engulfing thousands of these small molluscs. An analogous species, the *C. Australis*, appears equally abundant in the polar regions of the southern hemisphere.

CLASS XVI.—GASTEROPODA.

It is in the animals of this class that we find the characters of the Mollusca most prominently displayed, namely, the high development of the nutritive apparatus, with very feeble powers of locomotion. In all the more perfect forms, which are usually carnivorous, a distinct and prominent head exists, furnished not only with *tentacula*, or feelers, but also with eyes, and with what appear to be rudiments of organs of smell and hearing. In this part, we usually perceive that *symmetry* or correspondence between the two halves, which has been spoken of as characterising the animal organs in general; whilst in the posterior part of the body, which is made up of the organs of vegetative life, this symmetry is seldom to be discerned. They have the power of crawling from one place to another, by means of the expanded muscular disc or foot with which they are furnished; and as this foot proceeds from the belly or under surface of the animal, the class receives the name given to it. The mode in which it is used may be well seen by placing a snail or slug on a piece of glass, and looking at it from the under side. Many of those which inhabit the water can swim with considerable rapidity; but this power is chiefly possessed by those species which have no shell, or but a very slight one, and can bend their bodies in any direction.

The general character of the shelly structure, where it exists, is the same as in the *Conchifera*. It is in general composed of one piece, and called a *univalve*; in some instances, however, it is a *multivalve*; and in many species there is a small *operculum* or lid to the mouth of the shell, which may in some degree be regarded in the light of a second valve. The body is attached to the interior of the shell by muscles which can withdraw it or project it at the will of the animal; and the operculum can be drawn down upon the mouth with considerable force. It is the habit of some species, (as the *Limpet* and *Haliotis*), to attach themselves, by the expanded surface of the foot, to rocks, &c.; these are able to draw the shell closely down upon the rock, with great muscular power, just as the *Conchifera* draw together their valves; a short interval existing, however, when the animal is not alarmed, for the admission of water or air to the cavity of the shell. A very slight irritation will cause the animal to draw the shell close down on the rock, from which it is then very difficult to detach it.

The shell is formed, as in other Mollusca, by an exudation from the mantle; and is enlarged at intervals, in accordance with the increasing size of the animal. In some, the addition of an entire new interior layer, projecting beyond the old one, is made at every such period, as in the *Conchifera*; but in others the new matter is secreted only at the edge of the previous shell, and is joined on, as it were, to it; in these the line of addition is usually marked by a prominent rib on the exterior, but the interior is beautifully smoothed off.

The forms of the shell in this class vary extremely; but those which appear most widely separated may be shown to be connected by intermediate links. The open cone of the *Limpet* may be regarded as one of the simplest forms; in an allied genus, the *Pileopsis*, we find the point prolonged, and somewhat rolled upon itself; and by various links of this kind, we are brought to the regular spiral of the snail. From this we may return to the long straight form by the *Scalaria*, in which the coils of the spire touch each other only by their ribs; and by the *Vermetus* and *Magilus*, in which the commencement only of the shell possesses a spiral form, the remainder being prolonged into a straight tube. When the shell is spiral, and the point and mouth are

not in the same plane, a sort of central pillar is formed, like that round which a spiral staircase is constructed. This is called the *columella*; and it is usually grooved at its lower part, for the passage of water to the respiratory organs, which are placed within the shell.

The margin of the shell is not unfrequently fringed with spines, as in the *Murex*; these are formed, like similar appendages in the *Conchifera*, by prolongations of the mantle; and the dissimilar number of them in different specimens has caused the establishment of many species, which, now that the habits of the animal are better known, prove to be but different forms of the same. For it has been ascertained that the animal has not only the power of forming new spines, but of removing old ones, especially such as would interfere with the continued growth of the shell. The edge of the mantle is applied against their bases, and a kind of absorption of shelly matter seems to take place—a notch being formed, which causes them to be easily broken off. Various analogous changes are produced by a similar action in other shells, the portions first formed being wholly or partially removed. Sometimes the walls of the older portion are thinned, for the purpose of lightening the shell; and in other cases the top of the cone is altogether removed, a groove having been formed around its interior, which renders it so weak as to be easily broken off: in these last cases, the animal previously withdraws itself from the part that is thus to be separated, and throws a new partition across, by which

Murex Tenuispina.

Young Shell.

Adult Shell.
Pteroceras Scorpio.

the top of the shell remains closed after the division. A shell thus deprived of its apex is said to be *decollated*.

It is not only by such removals that the form of univalve shells undergoes a great change. Sometimes additions are made to them, which completely alter their figure, so that two individuals of different ages would be scarcely supposed at first sight to belong to the same tribe. But in all these cases the form of the young shell may be traced in that of the adult. The preceding figures of the *Pteroceras* show this change in a moderate degree; in other genera it is much more remarkable. In another group of shells, of which the common *Cowry* is an example, a still more curious alteration takes place. In the young shell the edge is sharp, and the mouth or opening of considerable breadth. This state continues as long as the shell is increasing in size; but when it has arrived at adult age, the outer lip is thickened, and brought so near the other as to leave but a narrow chink between them. At the same time, a prolongation of the mantle on each side deposits a new layer of shelly matter on the outside of the previous one; and as the two prolongations meet along the back (the line of their junction being usually evident on the shell), this additional coat, which is very hard and *porcellanous* in its texture, encloses the whole previous shell.

Young Shell.

Adult Shell.

Cypræa Exanthema.

The *operculum* is principally confined to the aquatic Gasteropoda. It is sometimes of the same texture as the shell itself, and sometimes horny. It does not always close the entire mouth of the shell, but it is sometimes made to fit it, at all stages of growth, with the most beautiful accuracy. Some of the land species also possess an operculum; but in general they are destitute of it, and they form during hibernation a temporary closure to the mouth of the shell, by a viscid secretion, which hardens into a thin plate, and includes within it a bubble of air. Behind this, a second and even a third similar partition is occasionally found, as in the common snail.

The subdivision of this extensive class into orders, may be best effected by arranging the different tribes according to the character and position of the respiratory organs. The following are those adopted by Cuvier:—

1. **PULMONEA.** These are terrestrial species, adapted to breathe the air by means of a pulmonary sac or air-cavity, the orifice of which they can open or close at will. Many have no shell.

2. **NUDIBRANCHIATA.** These, as well as all the succeeding orders, are aquatic, being adapted to respire water by gills, like other Mollusca. The animals of this order have no shell, and they carry their branchiæ, which present various forms, on some part of the back.

3. **INFEROBRANCHIATA.** These are similar in many

respects to the preceding, but the branchiæ are situated under the margins of the mantle.

4. **TECTIBRANCHIATA.** In the greater part of the animals contained in this order, the branchiæ are situated upon the back or on the side, and are covered in by a fold of the mantle, and this fold usually includes a shell more or less developed.

5. **HETEROPODA.** This is a small order, characterised by the peculiar form of the foot, which is not spread out horizontally, but compressed vertically into a sort of fin. They carry their branchiæ, the tufts of which are generally protected by a shell, upon the back.

6. **PECTINIBRANCHIATA.** The animals of this order, to which belong all the spiral shells, except those of the Pulmonea, are so named from the comb-like form of their gills, which are usually situated in a cavity behind the head, corresponding with the respiratory sac of the Pulmonea. This is by far the most numerous order of the whole.

7. **TUBULIBRANCHIATA.** These have many affinities with the last order, but the shell is spiral only at its apex, where it is commonly fixed to (or rather enclosed by) other bodies, and is prolonged in the shape of a tube more or less regular.

8. **SCUTIBRANCHIATA.** In these, also, there is a considerable resemblance to the Pectinibranchiata in the form and position of the gills; but the shells are very open, scarcely in any degree spiral, and cover the body and gills like a shield; and they also differ essentially in their mode of reproduction.

9. **CYCLOBRANCHIATA.** These molluscs have their gills disposed in little tufts under the margins of the mantle, much as in the Inferobranchiata; but they have shells, which are spread out over the body, and differ from that order in their mode of reproduction.

Order I.—Pulmonea.

Although the greater part of the Molluscs of this order live on land, some are aquatic; but these, like the aquatic air-breathing Insects and Vertebrata, are obliged to come occasionally to the surface to breathe. They all feed chiefly upon vegetables, and many of them exclusively so; but some are extremely voracious, and will devour almost any organised matter that falls in their way. They are diffused through all climates, particular species being restricted to each. Those without a shell, commonly known as Slugs, constitute the family *LIMACINÆ*. In the common *Slugs*, as in most of the terrestrial species of this order, we observe a prominent head, with four tentacula, and at the end of the longer pair the eyes are situated. These tentacula can be drawn inwards, by a process resembling the inversion of the finger of a glove. On the back there is a kind of shield or disc formed by the mantle, which sometimes encloses a small shell. This shield covers the pulmonary sac, the opening of which is on its right side, and the head can be withdrawn beneath it. The *Testacella* is a kind of slug which has the disc of the mantle at the posterior extremity, and this always contains a small shell. This animal, which feeds largely on earth-worms, is abundant in the south of France, and has lately been introduced into the gardens of this country, where it is multiplying rapidly.

The *Snails* and their allies, constituting the family *HELICINÆ*, are closely allied to the Slugs in organisation; differing in but little else than the possession of a shell into which the body may be withdrawn. The common garden-snail of this country, and the *Helix pomatia*, or edible snail of France and Italy, are well-known examples of this family. More striking ones are to be found, however, in tropical climates; where some species of the genus *Bulimus* attain to great size, the eggs being as large as a pigeon's. In some species the direction of the coils of the shell is opposite to what it is in other spiral shells; such are said to be *reversed*. A European species of this genus is one most remarkable for the decollation of its shell. Another large snail of tropical climates, as the *Achatina*, which feeds on trees and shrubs, chiefly on the western coast of Africa, and in

the West Indies. Several of its species are distinguished by the beauty of their colours.

The aquatic Pulmonæa have only two tentacula. From the necessity of coming to the surface to breathe, they can only live in water of inconsiderable depth; and they chiefly inhabit ponds and shallow streams, or the banks of rivers. Some, however, live on the sea-shore. The *Planorbis*, the shell of which is quite flat, having all its coils upon the same level, is a very common genus in this country; as is also the *Lymnæa*, which feeds upon seeds, as well as the softer parts of plants, and the stomach of which has a very muscular gizzard.

Order II.—Nudibranchiata.

The animals of this order, which might be designated Sea-Slugs, are all marine; and being adapted to breathe water at any depths, and also, in many instances, to swim with facility, they are often found at a great distance from land. When they swim, it is usually in a reversed position, the foot being turned upwards; this is made concave by muscular action, so as to serve as a kind of boat, the buoyancy of which keeps the animal at the surface without effort. This order is a very numerous one, and some of its species attain a considerable size; but, from their habits, little is known of them.

Order III.—Inferobranchiata.

The few Molluscs contained in this order differ but little from the last, except in the position of their gills, and their incapability of swimming. They are, therefore, confined to the sea-shore; where they subsist, as do the Nudibranchiata, upon sea-weeds and other aquatic plants.

Order IV.—Tectibranchiata.

This order begins to show an approximation towards that disposition of the gills which characterises the great bulk of the class; the animals composing it are marine, and live chiefly on the shore or on floating sea-weeds. A very characteristic example of the order is the *Aplysia*, commonly termed Sea-Hare, which is abundant on many parts of the British coasts. Its vernacular name is probably derived from the peculiar form of the superior pair of tentacula, which are flattened and hollowed, like the ears of a quadruped. The head has a very distinct neck. The branchiæ consist of leaflets arranged in a complex form, and situated on the back, beneath a fold of the mantle, which also encloses a flat horny shell. The digestive apparatus is very complicated; consisting of a membranous crop like that of birds, a gizzard having cartilaginous walls, and a third stomach beset with sharp hooks in its interior. These animals feed on sea-weed. They are very sluggish in their movements; but have a peculiar means of defence, consisting of a deep purple liquid, which they can discharge from the edge of the mantle when alarmed, and by which the surrounding water is discoloured, so that they cannot be discerned.

Order V.—Heteropoda.

This is a very small order; but the animals contained in it differ remarkably from all other molluscs. At the edge of the vertical muscular plate, which has been mentioned as occupying the position of the foot in the other Gasteropoda, is a small conical sucker, by which the animal can attach itself, and which represents the expanded disc of other orders. The gills are placed on the back, and close behind them are the heart and liver, which seem, as it were, external to the body. In one of the few genera which the order contains, these parts are protected by a small shell, whilst in another there is none. The body, consisting of a semi-transparent gelatinous substance, enclosed in a muscular envelope, is elongated, and generally terminated by a compressed tail; this body can be distended with water. The animal swims in a reversed position, the fin-like foot being uppermost, and the shell depending below. They are limited to warm latitudes: one species

of the *Carinaria* inhabits the Mediterranean, and occasionally appears on particular coasts in large numbers; whilst others are peculiar to the tropics, where most of the allied genera also exist. The shell of the *Carinaria* is interesting, on account both of its extreme delicacy and fragility, and on account of the strong resemblance which that of the Argonaut or Paper-Nautilus bears to it.

Order VI.—Pectinibranchiata.

This order is not only by far the most numerous in the whole class, but contains the animals which may be regarded as its most characteristic examples. They have all two tentacula and two eyes, sometimes raised on stalks, as in the snail. The mouth is prolonged into a sort of proboscis; and the tongue is furnished with little hooks or recurved spines, which enable it to wear down the hardest bodies by slow and oft-repeated action. The cavity in which the gills are fixed occupies the last whorl of the shell; and in some of the order there is a tubular prolongation of the mantle, termed the *siphon*, for the purpose of conveying water into this cavity, so that the animal can breathe without leaving its shelter. By the presence or absence of this organ, and by the form of the shell, which here appears to bear a sufficiently constant relation with that of the animals, this large group may be arranged under the following families:—1. *TROCHOIDÆ*, in which there is no siphon, and which have the mouth closed by an operculum. Of this the common periwinkle is a characteristic example, though very small in proportion to tropical species. 2. *CAPULOIDÆ*, which have a wide open shell, very much like that of the limpets, without operculum or notch at the margin for the passage of a siphon. 3. *BUCCINOIDÆ*, which have a spiral shell, and a canal at the end of the columella for the passage of the siphon; this is sometimes extremely prolonged, as in the *Murex*; and the genera exhibiting this character are all carnivorous in their habits. To this family belong the animals forming the greatest number of marine univalve shells preserved in cabinets.

Order VII.—Tubulibranchiata.

The Molluscs of this order construct an irregularly tubular shell, which so much resembles that formed by certain Annelida, as to be scarcely distinguishable from it. They are very few in number.

Order VIII.—Scutibranchiata.

This order is also a small one, containing but two principal genera, which do not differ widely from the limpets, except in the disposition of the gills. The shells are very open, without an operculum, and the greater number are not in any degree spiral. In the *Haliotis*, the shell is slightly twisted; and from a faint resemblance it is thought to bear to the ear of a quadruped, it has been called the Sea-Ear. This animal, in its living state, is one of the most beautiful of Gasteropods, on account of the variety and richness of its colours. Its shell, when the surface is polished, possesses a pearly lustre, with resplendent metallic hues. It is consequently much sought for as an ornament.

Order IX.—Cyclobranchiata.

The general form of the *Limpets*, which principally compose this order, is well known; and the peculiarity in the position of their gills has already been mentioned. Closely allied to the limpets in general structure, but differing remarkably in the formation of the shell, are the *Chitons*, of which some small species inhabit our shores, but which attain to much greater size between the tropics. Their shell is composed of a number of plates arranged behind one another with great regularity, and connected by a very complex series of ligaments and muscles, which reminds the naturalist of those which unite and move the different segments in the articulated animals.

ZOOLOGY—(CONCLUDED).

CLASS XVII.—CONCHIFERA.

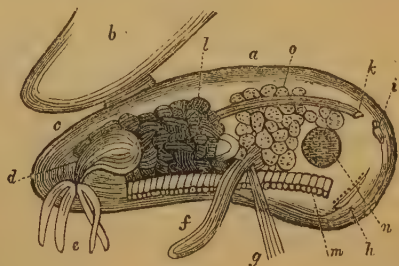

THIS class is nearly synonymous with that of *Bivalves* in the Linnæan arrangement, since all the animals which construct bivalve shells belong to it; but it also contains a few species whose shells are *multivalve*, and some others in which there appears at first sight an entire departure from the usual form. The molluscs belonging to this class are, in common with the *Tunicata*, destitute of a head; that is, the mouth is not situated upon a prominent part of the body, nor assisted in its choice of food by organs of special sensation in its neighbourhood, but the entrance to the stomach is buried between the folds of the mantle. Hence these two groups were associated by Cuvier into one class, to which he gave the name of *ACEPHALA*, or Headless Molluscs; but there is quite sufficient reason for separating them, on account of the superior organisation of the group at present under consideration.

The part of the structure of these animals which is best known, is the *shell*. This is composed of particles of lime, exuded from the surface of the mantle, in combination with a gluey secretion, by which they are united together. If one of the valves of a bivalve shell be examined, it will be seen to consist of a number of layers, of which the outer one is the smallest, each inner one projecting beyond the one which covers it. This is more evident in such shells as that of the oyster, in which the layers adhere loosely together, than in others in which they are more compact. The shelly matter is thrown out at intervals from the surface of the mantle; and as the animal enlarges at each interval, the new layer extends beyond the old one. In this manner, a constant relation is preserved between the size of the animal and that of its shell; and the addition of the newly-formed portions, not to the edge only, but to the interior of the whole previous shell, strengthens the latter in proportion to its increase in size.

The valves are connected together in various ways. In the first place, they are jointed by a *hinge*, which is in some instances so firm and complicated, that it holds them together when all the soft parts have been removed. This hinge is sometimes formed by the locking of a continuous ridge on one valve into a groove in the other, and sometimes by a number of little projections or *teeth*, which fit into corresponding hollows in the opposite valve. In the neighbourhood of the hinge (sometimes outside, sometimes inside, or both), is fixed the *ligament*, which is composed of an elastic animal substance; this answers the purpose of binding the valves together, and at the same time of keeping them a little apart, which may be regarded as their natural position. When the animal wishes to draw the valves closely together, it does so by means of the *adductor* muscle, which is fixed to the interior of both valves at some distance from the hinge, and of which the insertion can be easily traced by a somewhat rough depres-

sion of the interior surface of each valve. In some *Conchifera*, this muscle is single, and in others it is double, the two parts being even at opposite ends of the valve. Upon this character it has been proposed to found the primary division of the class into orders; but the classification thus formed is not a natural one, inasmuch as it brings together kinds which have little resemblance, and widely separates others which are closely allied.

In order to describe the general structure of the *Conchifera*, it will be advantageous to select some particular illustration; and the common *mussel* is well adapted to this purpose. On opening such a shell, it is seen that the two valves are lined by a membrane which corresponds with the tunic or *mantle* of the *Tunicata*. This is divided into two halves along a considerable part of the edge of the valves, but is united near the large end. In some *Conchifera*, as will be presently noticed, the two halves of the mantle are separated along their whole extent; whilst in others, as in the *Tunicata*, they are completely closed, with the exception of the two orifices for the ingress and egress of water, which are sometimes drawn out into long tubes. In the mussel, the water enters through a slit in the closed part of the mantle, and passes out by another in its neighbourhood; but the water thus introduced is principally for the supply of the gills, as the mouth, or entrance to the stomach, is placed at the small end of the shell, where the mantle is quite open, and can take in food from the surrounding water, which comes into free contact with it. The gills in all *Conchifera* consist of four riband-like fringes, fixed to the mantle along the edge of the shell most distant from the hinge. Near

Interior of Mussel: *a*, right valve; *b*, left valve; *c*, hinge; *d*, stomach; *e*, tentacula; *f*, foot; *g*, byssus; *h*, branchial orifice; *i*, vent; *k*, termination of intestine; *l*, liver; *m*, gills; *n*, adductor muscle; *o*, ovary.

the small end of the shell is seen the stomach, with the short tube leading to it, the orifice of which is furnished with four tentacula or feelers. To the right of this is seen the long and complicated intestinal tube, with the liver lying in separate masses amongst its folds. And

nearer the large end, the cavity of the shell is chiefly occupied by the ovum, in which the eggs are formed. Close to this is the powerful adductor muscle, by which the valves can be drawn together with considerable force. The intestinal tube is seen to terminate near the opening at the posterior (or right-hand) extremity of the shell, which discharges its contents, and serves for the exit of the respiratory current.

The foregoing description will apply, with slight variations, to the structure of almost all Conchifera; but we have now to notice two organs, which are absent in some, and in others more largely developed than in the present instance. From the lower part of the shell, passing out between the separate edges of the mantle, is seen the *foot*, a fleshy muscular organ, somewhat resembling the tongue of higher animals, and not containing any hard support, or being protected by any envelope. This foot, which is the only special locomotive organ possessed by the Mollusca of this class, serves a great variety of purposes, sometimes enabling the animal to leap with considerable agility along a hard surface, sometimes being used to bore into the sand or mud, and sometimes serving only to affix the animal to some firm support. From the base of this foot there proceeds, in the mussel, a band of hair-like filaments, forming what is called the *byssus*. These sometimes exist in great abundance, and serve, by being fixed by their extremities to the shore or bottom of the sea, to anchor the shell, and yet to allow the animal considerable freedom of motion within certain limits. Frequently the byssus is altogether absent.

The Conchifera have usually more power of locomotion than the Tunicata. Some of them, however, as the oyster, are attached to one spot during all but the earliest period of their lives. Others adhere by the byssus, or by the foot, by which they obtain a certain range; and others are free during the whole of their lives, swimming and leaping with considerable agility. In these movements some of them appear to be directed by powers of sight, and in these are perceived small red spots at the edges of the mantle, which are believed to be eyes. They do not appear to have much choice of food, nor are they provided with any other means of obtaining it than the ciliary action, which introduces constant currents of water into the mouth. In general they do not attain any great size, but they are on the whole larger than any Molluscs except the Cephalopoda; and a few species attain considerable dimensions—a *Pinna* having been known four feet long, and a *Tridacne* (Giant Clamp-shell) having been known to weigh 600 lbs. They are distributed over the whole globe, principally frequenting the shores or shallows. Each region has certain species peculiar or most abundant in it, and there are few which are not limited to one hemisphere. The temperate zone appears as favourable to the development and multiplication of some species as the torrid zone to others; but the largest kinds are only found in warm latitudes.

In the subdivision of this class into orders, the degree in which the two lobes of the mantle adhere along the margin of the shell, is the character chiefly rested on; the presence or absence of the foot, and of the byssus, also, are important characters; and along with these the structure of the hinge should be attended to. On these grounds, the five following orders are established by Cuvier:—1. OSTRACEÆ, the *Oyster* tribe, in which the two halves of the mantle are separated the whole way round, or the foot absent or very small: they are usually fixed by the shell to solid bodies. 2. MYTILACEÆ, the *Mussel* tribe, in which the mantle remains open in front (at the end where the mouth is situated) and closed behind, an aperture being left for the egress of the fluid. They have a foot strong enough to crawl by, and commonly affix themselves by a byssus. 3. CHAMACEÆ, or *Clamp-shells*; in these the mantle is closed, with the exception of three apertures, two of which are for the ingress and egress of water, and the third for the passage of the foot, which is here usually more powerful. 4. CARDIACEÆ, or *Cockle* tribe, in which

the mantle is not only closed, but extended at the respiratory apertures into tubes of greater or less length. The foot is very strong. 5. The INCLUSA, in which the mantle has only one opening for the passage of the foot; at the posterior end it is prolonged into tubes of great length, that can be extended far beyond the shell, as in the common *Solens* or *Razor-Shells*.

Order I.—Ostraceæ.

The Ostraceæ, of all these orders, exhibit the nearest approach to the Tunicata, both in the absence of the foot, the entirely fixed condition of the body, and in the low grade of their organisation in general. The shell itself is usually fixed by adhesion to other masses; in a few, the animal is attached by a byssus; and some species, which are unattached, have a slight power of changing their place, by suddenly closing their valves and squirting out the water that was between them. In the true *Oysters* there are no teeth in the hinge, which is held together by the ligament only. Several species exist, some of which are as abundant in tropical regions as the common Oyster of temperate seas is on the shores of Britain. Their continued abundance, notwithstanding the large quantities constantly being consumed, is less surprising when we reflect upon their astonishing fertility, as many as 1,200,000 eggs having been detected in a single individual. The *Pecten* have a hinge like that of the Oysters, but differ in having the surface of the valves raised up into ribs, and in having two angular projections, commonly termed *ears*, by the sides of the hinge. Many of them are very elegantly coloured, and they are the most active of the whole order, being entirely unattached, and swimming with greater quickness than would have been expected from their imperfect means of locomotion.

The foregoing tribes of Ostraceæ, and many more which might be enumerated, are distinguished by the presence of only one adductor muscle; in the remainder of the order, as in most other Bivalves, there exists a second. Among these may be first mentioned the *Etheria*, which is a sort of fresh-water oyster. The *Avicular*, which furnish the greater number of the pearls so highly prized as ornaments, are commonly called *Pearl Oysters*, from their general resemblance to the same tribe. The valves are extended into ears or wings, on each side of the hinge; and these are frequently very long on one side. The pearl is produced from the same substance as that which lines the shell, and which is commonly known as mother-of-pearl. It seems usually to result from some irritation of the mantle, which causes it to excrete an unusual quantity of pearly matter at one spot; and grains of sand, or other small particles, which, by getting between the membrane and the shell, seem to have caused such an irritation, are often found in the centres of pearls. Sometimes, again, pearls are found at points where the shell has been pierced by a boring animal; and it has been proposed to cause the formation of pearls by perforating the shell; but the pearls so produced seldom have that regularity in their form which is as important to their value as is their size. Pearls are also produced within many other shells. The *Pinna*, or Wing-shells, approach the *Mussels* in many respects; they are remarkable for the length and silky character of the byssus by which they attach themselves to rocks, and which is collected in the Mediterranean for the manufacture of gloves and other articles, for which it is well adapted by its strength and durability.

Order II.—Mytilaceæ.

The order Mytilaceæ is well represented by the common *Mussel*, which has been already described. The various species of this group are extensively diffused; and from their abundance in particular localities, and their palatability, they serve as important articles of food. Belonging to this order are some remarkable *boring* shells, which have the power of penetrating hard rocks, and making deep holes, which are enlarged as they advance, in accordance with the growth of the animals,

and which, therefore, they cannot quit. By what means they accomplish this is unknown. The flattened form of the shell is a sufficient proof that it is not by mechanical action, as in some of the boring shells of the order *Inclusa*. The *Anodon* is a fresh-water mussel, closely allied in general conformation to those inhabiting the sea, but differing remarkably in the absence of teeth in the hinge, whence the name of the genus is derived. The *Unio* is another fresh-water genus, having a more complicated hinge. It is remarkable for the pearly aspect of the lining of the valves, and for producing small pearls, sometimes in considerable abundance. These are not so pure in their colour, however, as those of the *Avicula*, and are but little esteemed. Some species of *Unio* are common in the lakes and rivers of Britain, but the greater number are peculiar to North America; many of these are remarkable for their size and colour. There are some marine *Mytilaceæ* allied to the *Unios*, one of which burrows in coral.

Order III.—*Camaceæ*.

The order *Camaceæ* includes but a comparatively small number of species, most of which are peculiar to tropical climates. The most remarkable is the *Tridacne gigas*, or Giant Clamp-shell, of the Indian Ocean. When young, this animal attaches itself to rocks by means of its tendinous foot, which serves as a sort of byssus; but when its shell becomes so massive that it is in no danger of injury, it detaches itself, and the groove of the shell is filled up. These animals, with their shells, sometimes attain the weight of many hundred pounds. Smaller specimens are often brought to this country; the valves being used to receive water from small fountains, &c.; and, on the continent, they are employed as reservoirs of holy water in the churches. The foot has a structure so tough, that, to separate the shell attached by it, it is necessary to chop it with a hatchet like a cable.

Order IV.—*Cardiaceæ*.

In the animals of the order *CARDIACEÆ*, or *Cockle* tribe, we usually find greater activity than in any others of the class. The foot now comes to be a very important organ, possessed of great muscular power, and capable of being applied to a variety of uses. Many of these animals bury themselves in sand or mud; and it is in these that we find the respiratory orifices prolonged into tubes. In the common *Cockle*, however, these tubes can scarcely be said to exist, the orifices not being prolonged beyond the shell. Its foot is very large, and can be bent nearly double in the middle; by doing this, and then suddenly straightening it, the animal is enabled to take considerable leaps. The hinge is very beautifully constructed; and the two valves lock closely together. The *Trigonia*, a very interesting genus, abundant in former ages of the globe, but now restricted to the shores of New Holland, seems allied to the cockle in the structure of its hinge and shell, in the size of its foot, and in its general organisation, although its mantle is divided into two lobes along the whole margin of the valves, as in the oyster. This is an instance of the impropriety of basing our classification on any single characters. There are other *Cardiaceæ* which obviously conduct towards the next order. Such is the *Tellina*, of which the valves, when closed together, gape at the posterior extremity; and through this passage there pass out two long tubes which terminate in the branchial orifices and funnel. These tubes have an elastic structure, and can be entirely drawn within the shell. These long tubes are seen also in the *Venus* and its allies, of which one species is remarkable for the long spines which guard its posterior end; and also in the *Mastra*, and the animals allied to it. In some cases the tubes are united along their whole length, and appear to be single; but they are always in reality double. All these animals are in the habit of burying themselves in sand or mud, or in stones; and the tubes serve to introduce fresh water from the entrance of their burrows.

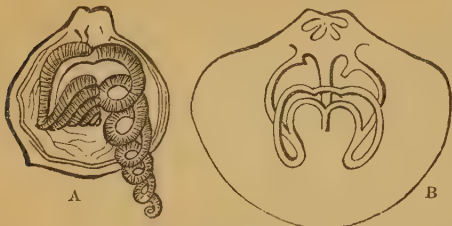

Order V.—*Inclusa*.

In the order *Inclusa* we usually find the valves, when joined together, presenting more or less of a cylindrical form, as in the common *Razor-shell*. A hollow is left at each end, and from one the foot is projected, through a passage in the mantle, whilst the other gives exit to the respiratory tubes, which are often prolonged to a great length. The animals live almost uniformly buried in sand or mud, in rocks or wood. The *Solen*, or *Razor-shell*, is a very characteristic example of the order, which contains, however, some forms that depart very widely from it. The foot, which can be projected from the lower end, is firm and pointed, and serves as an admirable boring instrument, by the use of which the animal can burrow in the sand with great rapidity, sinking very deep when alarmed. The *Mya* approaches, in the form of its shell, and in its general organisation, to the previous family; but some of its species also closely approximate the *Solens*. The *Pholas* is a very interesting genus, the animal of which nearly resembles that of the *Solen*, whilst the shell is formed of several pieces, and would thence be called a *multivalve*. There are two principal portions, and a variable number of accessory pieces. Some species of this genus bore in mud, others in rocks, and a few in wood. Their action seems purely mechanical. They fix themselves firmly by the powerful foot, and then make the shell revolve; the sharp edges of this commence the perforation, which is afterwards enlarged by the rasp-like action of the rough exterior; and though the shell must thus be constantly worn down, yet it is replaced by a new formation from the animal, so as never to be unfit for its purpose.

We now pass on to some very remarkable forms of this order, in which the bivalve character of the shell gradually disappears, being replaced by a new structure of which no examples have been yet seen. The *Teredo*, or Wood-worm, as it is commonly termed, is an animal of the same general organisation as the *Pholas*; but its valves are smaller in proportion to the body, and its tubes still more prolonged—at least when the animal may be regarded as full-grown. By means of the mechanical action of its valves, it perforates timber, in the same manner as the *Pholas* penetrates stone. As it advances, the respiratory tubes are prolonged, so that their orifice remains at the entrance of the burrow, which is very small in proportion to the cavity formed by the animal as it increases in size. This orifice is furnished with a pair of valve-like shelly plates, termed *palmulae*; by the action of which a current of water is driven towards the body of the animal, in order to serve for its respiration, and at the same time for the supply of its food. The gallery is lined by a calcareous exudation from the surface of the tubular prolongation of the mantle, which forms a kind of secondary shell. The *Teredo* is an animal extremely destructive to timber, especially in warm climates, from which it seems to have been originally introduced into the seaports of Europe. In other genera the valves are lost in the shelly tube, so that the ordinary structure of the class is no longer apparent.

Besides the orders now described as composing the class *Conchifera*, there is a very curious group which should also be included in it, although established as a separate class by many naturalists. This is the group of *BRACHIOPODA*, containing only three genera at present known, namely, *Terebratula*, *Lingula*, and *Orbicula*; but formerly of much greater comparative importance. These animals have all bivalve shells, differing in no essential particular from those of the *Conchifera* in general. The two former genera are attached, however, by a footstalk proceeding from an opening in one of the valves near the hinge, to solid substances; and in this respect they have an affinity with the *Tunicata*. The *Orbicula* is attached, like an oyster, by one of its valves. They bear considerable resemblance to the *Tunicata*, also, in the structure of the nutritive system—the digestive apparatus, heart, gills, &c. But

in the complexity of the muscular apparatus provided for giving motion to the valves, they much surpass the highest of the other Conchifera. There are not only several muscles provided for the closure of the shell, but another set to open it—an organisation which no other Bivalves possess. The most peculiar part of their structure, and that from which they derive their name, consists in the presence of two very long arms or tentacula, between the origin of which the mouth is situated. These can be projected to a considerable distance from the shell, or drawn in and coiled up spirally within it. They do not appear, however, to seize upon prey; but rather, by means of the cilia with which they are fringed, to create currents which may bring food to the mouth. In the Terebratula, these

Terebratula:

A, valve with the spiral arms; B, valve with arms removed.

arms are affixed at their bases to a very curious framework within the shell, the use of which is uncertain; but it is believed to aid, by its elasticity, in separating the valves from each other. This framework is most complex in the species in which the arms are shortest. The species of Brachiopoda at present known, live at great depths in the ocean; and many of their peculiarities seem to have reference to that particular condition. They are distributed through all latitudes.

CLASS XVIII.—TUNICATA.

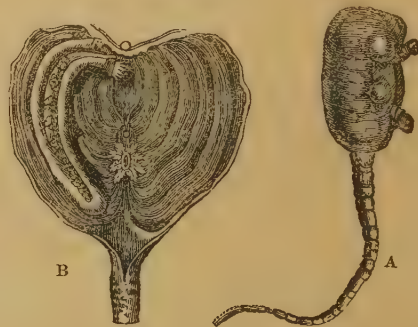

The lowest and simplest of the molluscous classes is that to which the name of Tunicata has been given, in order to mark the peculiar structure of the animals composing it. They bear a general resemblance to the animals which form bivalve shells, but are of inferior organisation. They are peculiarly distinguished from them, however, by the entire absence of any shelly envelope; and by the possession, instead of it, of a *tunic* or external coat, of greater firmness than the rest of the structure, which surrounds the whole body and affords it protection, besides being the medium of its attachment to the fixed substances upon which these animals usually rest. This external tunic is extremely variable in colour, consistence, and form. Sometimes it is dark, and of leathery toughness; sometimes even cartilaginous; and in many species it exudes a glutinous matter, by which particles of sand, gravel, comminuted shells, &c., are attached together, so as to form an additional envelope, which possesses great firmness. Sometimes, on the other hand, the whole body is extremely soft and delicate in its structure, and the tunic is a thin transparent membrane, the colour of which depends upon the intensity of the light transmitted through it.

The greater number of the animals of this class are attached, during the principal part of their existence, either to each other or to solid bodies. In a few species, a number of individuals are united by a stem which contains vessels establishing a connexion amongst them all; so that they closely resemble the compound Polypifera. More commonly, however, the Tunicata live in societies, each individual being distinct from the rest, but a number adhering together to form one mass, which is often enclosed in a common envelope. In other instances, each animal is completely separate from the rest, although a number are found in the same locality. Where this is the case, the animals are severally fixed

to rocks or other solid masses, either by the adhesion of the tunic itself, or by a sort of footstalk prolonged from it.

The *tunic* is always provided with two orifices; these are sometimes placed near each other, and are sometimes at the opposite extremities of the body. One of these orifices serves for the entrance of water into the cavity of the mantle, the other for its exit. The great bulk of the body may be considered as a respiratory chamber, that is, a cavity lined with a membrane upon which the blood is plentifully distributed, in order that it may be exposed to the action of the air contained in the water introduced into it. Accordingly, a continual current of water is maintained by the action of the *cilia* (minute, constantly vibrating, hair-like filaments) which clothe the lining membrane; and this current also serves to supply food to the inactive creature which produces it. The true mouth, or entrance to the canal that leads to the stomach, is situated at the bottom of the *branchial sac*, or respiratory chamber; and part of the water introduced into the latter passes into the stomach, and after traversing the intestinal canal, and parting with whatever nutritive materials it contained, is ejected from the second orifice of the tunic, with the stream that has merely passed over the respiratory membrane.

In these actions nearly the whole life of the Tunicata appears to consist. Those which are adherent to rocks have no power of changing their place when once attached; and those which float in water, either singly or adherent to one another, seem to have no means of locomotion, except what they derive from the currents just described. The only other movement ordinarily noticed, is the contraction of the whole sac, which takes place when the animal is irritated in any way, the water contained in it being violently ejected.

Ascidia Australis: A, external aspect; B, internal structure.

The accompanying figure will give a general idea of the structure of one of these animals. On the right hand it is seen in its natural condition, with its attached footstalk; the two projections on the right side are short tubes terminating in the orifices by which water is introduced and expelled. On the left hand is shown the interior of the sac, which has been laid open; it is seen to be nearly empty, the intestinal canal on the left side occupying but a small proportion of the cavity; and the membrane lining it is disposed in folds, which are traversed by blood-vessels, so as to expose the greatest extent of surface to the action of the water, by the air contained in which the vital fluid is purified. The orifice by which the water enters this chamber is called the *branchial* aperture, because it is chiefly for the admission of water to the *branchiae*, or gills; and that through which it passes out is called the *funnel* or vent.

The division of this class into orders is most satisfactorily based upon the relative position of these two orifices, which have a close relation with the modes of life of two groups of animals respectively. In the *Ascidiae*, the two orifices approach one another more

or less closely, and the body is either immediately fixed to some solid mass, or attached to it (as in the example just referred to) by a footstalk. In the *Salpæ*, on the other hand, the two orifices are situated at the opposite extremities of the body, which usually has an elongated form. They seldom attach themselves to fixed objects, but float freely amidst the waters. Without any special means of locomotion, they are continually changing their place, by means of the currents of water they produce; for, the fluid being drawn in at one end and expelled at the other, they advance in the direction to which the branchial orifice points. The *Salpæ* are usually of much more delicate structure than the *Ascidie*. Some of the more interesting species of each group will now be noticed.

Order I.—*Ascidie*.

Although some of the *Ascidie* present a nearer approach to the animals forming bivalve shells, than do any of the *Salpæ*, it can scarcely be doubted that the group as a whole is inferior; and in it only do we find instances of that connexion of several individuals by a common stalk, through which blood passes from one to the other, which indicates an approach to the *Polypifera*, especially to the order *Ascidioidea*. In these compound *Ascidie*, a curious phenomenon is witnessed, which resembles the movement of fluid that will be described in one of the compound *Polypes*, the *Sertularia*. The stem which supports them contains two large vessels, which send off branches into the footstalks that support the several individuals. The branch from one trunk goes at once to the heart of each *ascidia*, which is but a simple bag, formed by a dilatation of the tube, having muscular walls; and that from the other is connected with the vessels which return from the intestinal tube and respiratory membrane, which are supplied with branches proceeding from the heart. The blood may be observed ascending for a time towards the heart through the first of these trunks, passing thence to the general structure, and returning through the footstalk by the second. But, after a short time, the current is reversed, and the blood ascends through what was before the returning trunk, and descends through the heart. In a short time, the flow is again reversed; and this change is repeated with great regularity, just as in the *Sertularia*. Although this alternation may be best observed in these compound *Ascidie*, in which the direction of the flow through the stem and branches may be clearly traced, there is reason to believe that it is common to the whole group of these curious animals.

Order II.—*Salpæ*.

The *Salpæ* are most abundant in tropical climates, and possess a greater delicacy of organisation than the *Ascidie*, being generally almost or completely transparent. Most of the species belonging to this group are also remarkable for their luminous properties. In no species does there appear to exist such an internal connexion as has been described in the lowest *Ascidie*; but scarcely any of them are entirely solitary. They generally associate together in masses of considerable extent, adhering either by their whole external surface, or by little projections from it, which seem formed for the purpose of attaching them to each other. Sometimes these masses assume the form of long bands, composed of *salpæ* adhering together side by side, all lying in the same direction. In others, again, the form of a star is presented, by an arrangement similar to that of the *Botryllus*. One of the most interesting of all, however, is the *Pyrosoma*, in which a number of these stars are piled, as it were, on one another, so as to form a cylindrical tube, which is closed at one end. The orifices of all the animals composing it are disposed in the same direction; so that water is constantly being drawn in on the exterior and expelled from the interior of the tube; as it can only pass out at one extremity, a current of sufficient force is produced to occasion the steady movement of the aggregate mass in the contrary direction. The luminosity of the *Pyrosoma*,

the length of which varies from five to fourteen inches, is extremely vivid.

SUB-KINGDOM.—RADIATA.

The general fact, that, in every complete natural group, there are some members which exhibit most plainly its characteristic peculiarities, whilst there are others in which these cannot be distinctly traced, or are altogether obscured, is nowhere more evident than when we compare together the different classes which are associated into this sub-kingdom. For whilst in some we find the *radiated* arrangement of parts almost invariably preserved, and, if left at all, only slightly departed from, we can only trace it indistinctly in others, and in others, again, it cannot be at all perceived. Thus, when we examine a *Star-Fish*, a *Medusa*, or a *Sea-Anemone*, we observe that they all have a circular form, that the mouth is in the centre of one of the surfaces, and that the several parts arranged round these are but repetitions of one another; and an internal examination would show the contained organs to have the same character. If from these we pass to certain other species of the same groups, we should find the external form slightly modified, being prolonged or shortened in one particular direction, and the disposition of the interior organs no longer radiated. Again, in the *Sponges*, all trace of a circular arrangement of parts disappears. Yet these, and other groups in which the radiated type is equally absent, must be associated with the classes more characteristic of it, on account of their general conformity of structure, and in some instances their very close alliance with them.

Moreover, in comparing the different forms of this group, we see exemplified another general principle, namely, that the *aberrant* members of it—those which depart most widely from its regular type—connect it with other groups. For, among the species in which the radiated arrangement is obscure, we find some that conduct us towards the *Mollusca*, and others that lead us to the *Articulata*; whilst in the *Sponges* and *Coralines* we have an evident approximation to the vegetable kingdom. So close, indeed, is this approximation, that there are many beings of which the true character is yet in doubt; they live, and grow, and multiply, very much in the manner of plants, and it cannot be ascertained with certainty whether the feeble motions they exhibit are to be regarded as spontaneous or not.

The great diversity, not only in form, but also in degree of organisation, that exists amongst the *Radiated* classes, prevents much being stated of their general characters that shall be applicable to all of them. Thus, although the skeleton is external in some species, as the *Sea-Urchin* and *Star-Fish*, it is internal in others, as the *Corals* and some of the *Jelly-Fish*. Although most of them have a distinct mouth and stomach for the reception of aliment, others imbibe it, like plants, only by absorption through their exterior. Although some exhibit a high degree of sensibility, others are so apathetic as scarcely to manifest any feeling of injury when severely wounded.

The class *POLYPIFERA*, containing the coral-forming animals, may perhaps be regarded as the most characteristic of the group. These animals usually associate themselves together into compound masses, of which every part is capable of existing independently of the rest, and each polype exhibits in itself the radiated structure, which cannot be detected in the entire mass; but all have a certain degree of connexion with each other, which may be compared to that existing among the different buds of a tree. Even the species which do not form solid structures, such as the *Sea-Anemone*, remain almost constantly attached to the same spot.

The *ACALAPHÆ*, commonly termed *Sea-Nettles*, or *Jelly-Fish*, have no such tendency to aggregation, and they never attach themselves to solid bodies, but wander at large through the ocean. By these characters, and

by their extreme softness, these animals are readily distinguished.

The ECHINODERMATA also live solitarily, and have the power of free movement, except in a few species which approach the Polypifera; but they are readily distinguished from the Acalephæ by the density of their texture, and especially by the roughness of the integument, which is usually beset with prickles or spines, as in the Star-Fish and Sea-Urchin.

In the two following classes, no distinctly radiated structure can be seen:—

The POLYGASTRICA, which are ordinarily known as Animalcules, are beings of extreme minuteness and general simplicity of structure. In the absence of distinct organs for the various purposes of the economy, they correspond with the lower Radiata, but they differ in the extreme activity of their movements. A separate division of the animal kingdom might almost be formed for them alone, so difficult is it to assign them any place in the ordinary scale. Some of them exhibit a tendency to associate into compound structures, like the Polypifera.

The PORIFERA, or *Sponge* tribe, are of all animals those which approach nearest to plants, in the absence of the characters peculiar to the kingdom in which they are placed, and in the want of definiteness of form. Certain movements exhibited by them, however, and their close affinity with some of the Polypifera, render it proper that they should be classed among animals.

CLASS XIX.—POLYGASTRICA.

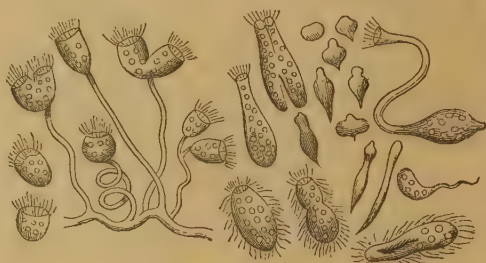

This class includes the greater part of those minute beings termed *Animalcules*, which have been, from the time of the discovery of the microscope, such fertile sources of wonder and delight, both to those who have themselves observed them, and to those who have heard from others of their marvels. Previously to that epoch, it was not suspected that beings existed of such minuteness as to be invisible to the eye, much less was any idea entertained of the extreme smallness of many species; and still more improbable and absurd would the statement have been deemed, that such beings are not of rare occurrence, but abound in every drop of stagnant water, and even exist in the whole mass of the ocean. Yet such has been shown to be the fact, and every improvement in the powers of the microscope has enlarged our ideas of the extent of animal life in the fluids of the globe; so that the philosopher is now ready to admit no limit to the possible minuteness of living beings, but looks to still further improvements in the microscope as a means of extending his acquaintance with them, and not as likely to set any bound to his inquiries.

Animalcules may be obtained without difficulty for microscopic examination during the warmer part of the year, by skimming the surface of ponds, especially those in which the water exhibits a red or green tinge, or in which it is covered with duckweed, or with the slimy film which may often be noticed. Many curious species frequent these situations; but the commoner ones may be obtained with even less difficulty, by placing soft vegetable matter, of almost any description, in vessels with water, and exposing the mixture to the sun and air for a few days. As soon as decomposition begins actively to take place, Animalcules may be detected in the fluid, and in a short time they often crowd it most densely. These are generally at first of a simple kind; but new species soon prevail, and those first seen disappear. Different kinds of vegetable matter seem to favour the development of the different species; and there are some Animalcules that can be produced in no other way than from an infusion of some particular substance. Asparagus stems that have been boiled will favour the production of Animalcules, with perhaps as much readiness as any vegetable matter; hay, chopped straw, the leaves of plants, and other common ingredients, may also be advantageously employed.

In the class Polygastrica are included all the most

minute species of true Animalcules, and some among the larger ones; but as a whole, the beings composing it are smaller than the Rotifera, and far smaller than those of any other class. The largest among them are but with difficulty seen by the naked eye, and of the dimensions of the smallest the mind can scarcely form an adequate conception, although they may be numerically stated. The class takes its name from the belief entertained by the celebrated Prussian naturalist, Ehrenberg (who has devoted almost his whole life to the study of the microscopic forms of existence), that the animals composing it may be characterised by the possession of many distinct stomachs or digestive sacs. There is some doubt upon this question, however; that which can actually be seen will be presently stated; and it will be preferable to enter no further into the question in this place.

The bodies of these Animalcules are of very soft consistence, and very transparent; so that they resemble flakes of very thin jelly. Their forms are extremely variable; and, in some species, the same individual at different times alters its shape so completely, that it could scarcely be recognised. Indeed, many mistakes have occurred from this cause. The softness of the tissues of the Polygastrica is also seen when, in swimming, they encounter an obstacle; there seems scarcely any limit to the change of form to which many will submit, in order to pass the obstruction. They are not all so flexible, however; for in some species the body is enclosed in a siliceous sheath of very great delicacy, which gives support and protection to the still more delicate structures it contains. It is the accumulation of such sheaths that has given rise to the collections of Fossil Infusoria (as they have been termed), which will be hereafter noticed. Sometimes the whole body is contained within the sheath; whilst in other instances a sort of trunk or foot may be projected from its opening.

Various Forms of Animalcules.

The bodies of the Polygastrica are usually fringed with cilia, by the vibrations of which they are assisted in their own movements, and also in the acquirement of their food. Sometimes these cilia are disposed along the whole extent of the edges of the body; in other instances they surround the mouth only, and from that part they are seldom absent.

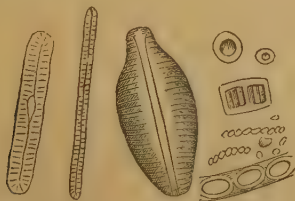

For some time after the discovery of the Infusoria, it was supposed that they must obtain their nutriment by absorption through the substance of their bodies, for no mouth, stomach, or alimentary tube, could then be discerned. But, by placing them in water, through which very small particles of colouring matter (such as indigo or carmine) were diffused, it was perceived that these particles are introduced into the interior of the body, and are collected in cavities hollowed from the general mass. And, subsequently, the improved powers of the microscope have enabled an entrance to the interior of the body or mouth to be discovered in almost every instance, and a second orifice in a considerable number of species. The mouth is commonly furnished with a border of cilia, and sometimes with a set of projecting bristle-like teeth, which are used in laying hold of smaller Animalcules, on which the possessor of this apparatus feeds. The introduction of food into the cavity of the body in those species which are destitute of this appendage, may be best watched by

diffusing colouring particles through the water in which the Animalcules are swimming. They are seen to be drawn into the mouth by the vortex or whirlpool occasioned by the action of the cilia; and soon after entering it, they are observed to be united together into little round balls, as if they had been compressed in a small spherical cavity. These balls are sent one after the other into the general cavity of the body, where they seem to lie in the midst of a soft gelatinous pulp, and in which they perform a slow revolution—the foremost ones escaping at intervals from the second orifice, whilst new ones are being pushed in from the mouth behind.

This is all that can as yet be certainly stated in regard to the digestive apparatus of the Polygastrica; since the opinion of Ehrenberg, that the whole body is occupied by a series of small distinct globular cavities or stomachs, connected by an intestinal tube, is not adopted by other naturalists. Nothing will therefore be said of his classification of these Animalcules, which is principally based upon characters furnished (according to his idea) by the arrangement of the stomachs.

The largest species of the Polygastrica probably never exceed 1-20th of an inch in length; the smallest at present known are about 1-2000th of a line in diameter; but there is no reason to suppose that this is by any means the limit of minuteness. They usually multiply by spontaneous division, the body of the parent splitting into two or more parts, each of which soon becomes a perfect being, capable of going through the same process. From observations which have been made upon the species in which these changes are most rapidly effected, it has been calculated that, under the most favourable circumstances as to food, temperature, &c., a hundred and forty million millions may be produced in four days—a degree of fertility which assists in explaining the almost universal diffusion of these Animalcules, and their sudden appearance in countless swarms.

Our ideas of the vast amount of animal life existing in this class have lately received a considerable extension by the discovery that their remains, minute as they are, not unfrequently accumulate into masses of great extent. It is only of those species in which the bodies are covered with an envelope containing earthy matter, that the remains can be thus preserved; and the substance formed by their aggregation seems to be an impalpable powder, such is the minuteness of each particle.* Such substances have long been known under various names. One is the Tripoli, or Rottenstone, used in the arts for polishing metals. Another is the siliceous meal which has been used in Sweden,

Fossil Remains of Animalcules, forming Tripoli.

on account of its supposed nutritious qualities, mixed in bread with flour and the inner bark of trees, in times of scarcity. Both these, as well as many other substances, consist entirely of the siliceous shields or envelopes of Animalcules, closely allied to, if not identical with, species at present existing; and the quantity of animal matter which is dried up in the latter, and which may be determined by the effect of heat (this dissipating the animal portion and leaving the siliceous particles unchanged), is sufficient to account for its nutritious properties.

* Of the larger species more than 180 millions are estimated to weigh only a grain.

CLASS XX.—ECHINODERMATA.

The class of Echinodermata, comprehending those well-known animals, the *Asterias* (Star-Fish), and *Echinus* (Sea-Urchin), takes its name from the prickly skin with which most of the tribes it includes are provided. But this is not an universal character; for some of the species, which border upon other groups, have a skin destitute of any appearance of spines. There is little difficulty, however, in distinguishing the animals of this class from all others, for in nearly the whole of them the radiated structure, or the arrangement of parts in a circular form, is very evident; and they are the only animals among the Radiata which have the power of moving from place to place, and have at the same time an integument firm enough to resist pressure.

Although the character and degree of organisation in the different subdivisions of this class may be regarded as about the same, the form of the organs, and the mode in which they are arranged, are very different, so that it will be better to describe each group separately. The class may be distributed into three orders; the *Stellerida*, including the Star-Fishes and their allies; the *Echinida*, including the Echinus and its allies; and the *Holothurida*, a group less commonly known, and differing much from the others.

Order I.—Stellerida.

The common *Asterias*, or Star-Fish, which may be taken as a type of the order Stellerida, is covered with a tough leathery skin, beset with prickles. The animal has the form of a star, with five or more rays springing from a central disc. In the middle of one side of the disc is situated the mouth, and this side, according to the usual habits of the animal, must be considered the lower one. The mouth opens into a globular stomach, which sends out prolongations into the several rays, but there is no intestine in this animal, nor any second orifice to the digestive cavity, so that the indigestible parts are rejected by the mouth, as in the Sea-Anemone.

Asterias: upper surface.

If the tough prickly skin be removed, it is seen that it is supported by a series of bony plates, beautifully jointed together. Along the under side of each ray, the plates exhibit a series of perforations, through which there issue, in the living state, a large number of minute tubes, which may be occasionally seen projecting on the outside. These tubes are termed the *feet*, on account of the use to which they are subservient. Every one of them is connected, on the interior of the shell, with a small vesicle or bag, which is capable of being distended with water by a system of vessels adapted to the purpose, and of contracting so as to force its contents into the tube. The tube consists of a delicate elastic membrane, covered with two layers of muscular fibres, the one circular, the other longitudinal, and furnished with a sucker at its extremity. When distended with water, the tube projects from the body; and, if the sucker be then applied to any moveable substance, it will be drawn towards the body by the elasticity of the membrane, when the distending force is relaxed. Although each sucker is small and weak, the combined efforts of many give the animal considerable power, not only of drawing prey towards the mouth, but of moving its own body from place to place.

The order Stellerida includes a large number of forms, having a general resemblance to the *Star-Fish*, but differing much in the relative proportion of the body and rays. Thus, in some species, the arms seem to make up the entire animal, no central disc being present, save that formed by their union. In others, the arms appear simply appendages to the central disc, to which the stomach and other important organs are

confined. In some instances, the arms send off lateral appendages; and these occasionally again subdivide, so that a branch-like structure is produced, such as we find in the *Comatula*.

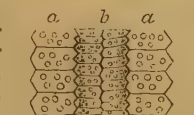

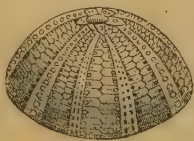

A very remarkable tribe, included among the *Stellerida*—once a group very important in its numbers, and in the extent of its diffusion through the sea, but now presenting only two or three comparatively small species—is that known under the name of *Crinoidea*, or lily-like animals. These are formed much upon the plan of the *Comatula*, but they are attached by a jointed stalk to solid substances, usually to the bottom of the sea. They thus remind us of the *Polypifera*, which they seem to connect with the *Echinodermata*. This group contains two principal subdivisions—the *Encrinurites* and the *Pentacrinurites*. The former are distinguished by the roundness of their stems, the joints of which being flat and perforated in the centre, are known under the name of wheel-stones, or St Cuthbert's beads. The latter have pentagonal stems. The former seem to have been the most ancient.

Order II.—Echinida.

In the *Echinida* we find the body usually of a somewhat globular shape, and enveloped in a firm shell, composed of a very regular series of plates jointed together. In the *Echinus*, the shell of which is commonly known as the Sea-Egg, we observe two orifices situated at the poles, as it were, of the globe. The larger of these orifices is the mouth: at the smaller one the intestinal tube terminates. The mouth, as in the star-fish, is generally directed downwards. It is furnished with a very curious apparatus of teeth, which are worked by powerful muscles, attached to projections of the shell, that may be seen on the inner margin of the mouth; and their points can even be protruded beyond the mouth, so as to lay hold of prey brought to them by the long tubular feet. By the action of the teeth, the food is ground down before it passes into the intestinal tube, which is here of considerable length, and takes a couple of turns round the shell before its termination. Round the second orifice of the shell are disposed the ovaria, which are very largely distended with eggs at some seasons, and are eaten under the name of the *roe of the sea-egg*.

It is the exterior organisation of these animals, however, that presents us with the greatest sources of interest. On looking at the *Echinida* in their living state, we see that most of them are covered with spines of considerable size, instead of with such small prickles as the *Asterias* bears. Moreover, these spines are seen to be moveable at their bases, and their power of motion is due to their peculiar connexion with the shell. Each spine is spread, at its root, into a cup-like form, and the hollow of this cup fits upon a little knob or tubercle projecting from the surface of the shell, so that a complete ball-and-socket joint is formed. The spines are connected to each other, and held on the shell by the skin which covers the latter, and which is attached around their roots; and it is by the contractions of this skin that they are moved.

On looking at the exterior of the shell of an *Echinus*, it is seen that the tubercles are arranged with great regularity, and that the larger ones are confined to particular rows of plates, which are hence called *tubercular plates*. Between these are smaller plates, commonly bearing smaller tubercles, and perforated with a number of minute holes, for the passage of the tubular feet; these are called *ambulacral plates*. The tubular feet, like the spines, are much longer than in the star-fish. They are always capable of being projected beyond the

Shell of *Echinus*: a, tubercular plates; b, ambulacral plates.

spines; and, taking an attachment by the suckers at their extremities, they can cause the shell to roll, as it were, upon the points of these. In some species, the spines are five or six inches long, whilst the diameter of the body is much less. The tubular feet often escape notice on account of their transparency; and the animal appears to be walking upon its spines, when it is merely resting upon them as fulcra, and drawing itself forwards by these curious organs. It is to be remembered that the body will weigh much less in water than in air, and thus may be supported upon spines of great delicacy.

The structure of the shell itself, and the mode of its increase, are not among the least interesting parts of the history of this animal. The shell is composed, as already stated, of a large number of plates disposed with great regularity, and accurately fitted together. These plates are usually of an hexagonal shape, but where large and small ones join, there is of course some modification. Now, it is obvious that a shell of globular form can only be regularly increased in all its dimensions by the equal growth of every part of it. This addition is provided for by the interposition of a thin layer of membrane, from which the shelly substance may be deposited between the edges of all the plates; and this membrane also answers the purpose of forming a connexion between the skin covering the shell and the organs of nutrition within.

These animals are generally found on sandy shores, and especially in little nooks secluded from the direct influence of the waves. Some of them excavate hollows in the sand by means of their spines, and one species even works its way into solid rock. Their food is of a mixed quality. Fragments of shells, *Crustacea*, and other marine animal products, are found in their stomachs, as well as portions of sea-weed. They obtain their prey whilst lurking in their hollows, by allowing their tubular feet to play loosely in the water around; and when any small animal touches the sucker at the end of one of them, it is soon secured by the assistance of others, and drawn within the range of the powerful teeth.

It is not in every species of *Echinida* that the globular form is so well marked as in the *Sea-Egg*. There are many in which the shell is more or less flattened, and in which one or both the apertures of the alimentary canal are out of the centre. In these the dental apparatus is either absent or comparatively feeble.

Order III.—Holothurida.

In the last order of *Echinodermata*, the *Holothurida*, we find the characters of the class remarkably blended with those of *Articulated animals*. The body is not enveloped in a hard shell, but in an elastic skin, destitute of spines or prickles. It retains, in some species, the globular form, but in many it is very much prolonged, so as to be almost cylindrical, and thus to resemble that of the *Worm tribes*; and it is occasionally even marked by transverse bands, indicating a division into segments. Still, however, a distinctly radiated conformation may be seen around the mouth; and some of these animals look as if a star-fish were set as a head on the body of a large worm. In the general conformation of the internal organs they correspond with the *Echinida*; but they are in some respects more complex, and the respiratory organs are constructed upon the plan of those of the *Articulata*. They thus form a very interesting link of connexion between the *Radiated* and *Articulated* sub-kingdoms.

The skin of most of the *Holothurida* is so very elastic, that they can change their size and form in a remarkable degree. They are capable, too, of swimming with considerable rapidity, and some of them crawl like slugs upon solid surfaces. Small species are occasionally found in British seas; but on some tropical shores they are very abundant, and grow to the length of eighteen or twenty inches. They are sometimes eaten by the poor on the Neapolitan coast; but in the Malay archipelago they are regularly sought, and conveyed to the

Chinese market, where, under the name of *trepang*, they fetch a high price.

CLASS XXI.—ACALEPHE.

The name of the class next to be described, the Acalephæ, is derived from the stinging power possessed by nearly all the animals composing it. The word is the Greek term for *nettles*; and by the designations *sea-nettles*, *stang-fishes*, &c., these animals are popularly known; as well as by another, also expressive of a character by which the group is distinguished—*jelly-fish*. It is rather difficult to give any description of the structure of the class that shall include all the members of it, so much do they vary among each other. They all differ from the Polypifera in being unattached to solid bodies, and in having the power of freely moving through the sea; and they differ from the Echinodermata in not being covered with a dense integument. Their extreme softness is one of their most remarkable characters. Some of them attain considerable size, yet with an almost entire absence of any hard support or framework; indeed, it is only in a few species that any such exists.

The tissues of the Acalephæ are so soft, that they seem almost like masses of jelly; whence originated their common name. They consist of a sort of network of animal filaments, the interspaces between which are filled up with water; and so large a proportion does this bear, that it drains away when the animal is kept out of its element for a short time, leaving but a thin film of membrane behind it.

The arrangement of the mouth, stomach, and other organs, is subject to great variation in the different subdivisions of this class, and we here encounter the very remarkable fact, of the existence of animals of complex structure and varied powers, which do not possess any regular mouth, but imbibe their food like plants by root-like filaments. Owing to the difficulty of examining the structure of beings which can be so imperfectly preserved, however, the organisation of many of the more curious species is as yet very imperfectly understood, and it will be better to confine ourselves here to the consideration of those most certainly known.

One of the commonest forms of this class is the *Medusa*, which is often seen floating in vast numbers on calm sunny days at a little distance from the shore. The animal consists of a large umbrella-shaped disc, from the under surface of which hang down four broad and long tentacula. Both disc and tentacula exhibit a very beautiful assemblage of colours, like those of the rainbow, when the rays of the sun are reflected from their surface. On the under side of the disc is seen the mouth, situated in the centre, and surrounded by the origins of the tentacula. This is the entrance to a stomach, which lies in the middle of the disc, and is surrounded by four ovarian chambers, having separate

as occupying the part corresponding to that included between the metallic stretchers of the umbrella), and this broad free margin is endowed with muscular powers, and performs a series of regular undulations, by which the animal is propelled through the water.

The extreme softness of the tissues of these *Medusæ* is an obvious reason why they should not expose themselves to the rough surface of the ocean, where they would be beaten to pieces by the waves—or to the proximity of the shore, from which they would soon receive fatal injury. Although so soft, however, they have the power of mastering prey of much firmer structure, and hard Crustacea, as well as other marine animals of high organisation, supply them with food.

The *Medusa* shares in another property possessed by most of the class, that of luminosity or phosphorescence. It is chiefly to the smaller tribes, accumulating in immense numbers, and so transparent as to escape notice by day, that the occasional phosphorescence of the sea is due. This very beautiful phenomenon may be seen not unfrequently on the shores of Britain; but it is most splendid in warmer seas, especially in the Mediterranean. In the midst of the diffused luminosity, caused by the glow of innumerable multitudes of small Acalephæ, and even of animalcules far smaller, the larger ones shine out like stars in the milky-way. The cause of this beautiful appearance is ill understood. It has been ascertained to exist in a secretion formed from the surface, which can be washed off, and can thus communicate the phosphorescence to various fluids, in which it seems to remain until decomposition has taken place. The light is rendered more brilliant, when exhibited by the animal itself, by any thing which irritates it; and this fact is observed in the case of most luminous animals.

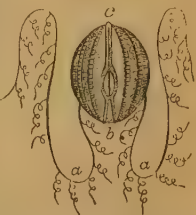

An interesting species, allied in general form to the *Medusa*, but differing from it in a remarkable particular, is the *Rhizostoma* (root-mouth). No mouth is seen in the centre of the inferior side of the disc, but the stomach sends canals into the substance of the tentacula, which terminate in a number of minute pores at the extremity of those organs. By these small pores, as by the roots of plants, nourishment is absorbed into the system, for the ends of the tentacula fix themselves like suckers upon the surface of the animal they have grasped, and imbibe its juices. These and other Acalephæ which move through the water by the undulations of their membranous disc, are included in the order PULMONIGRADA. All the Acalephæ of this order exhibit a very regular disposition of their parts around a centre, so as to be truly radiated animals. Some of them attain a diameter of two or three feet.

Another interesting species of this class is the *Berœ pileus*, a small animal not unfrequently found on the coast of Scotland. When at rest in the water, it looks like a bright globe of jelly, about half an inch in diameter. An opening is seen at each pole of the globe; one of these is the mouth, and at the other the alimentary canal, which runs straight across the body, terminates. Its surface is marked by eight bands, running, as it were, from pole to pole; these bands seem to be of firmer texture than the rest of the body, and on them are placed the rows of cilia, which can act either together or separately, so as to give every possible variety of motion to the body. Hence this animal, and others resembling it, are said to belong to the order CILIIGRADA. The *Berœ* usually swims, by means of them, mouth forwards, through the water, and thus a current of water is driven into the stomach, without any further effort on the part of the animal. But it is provided with other means of obtaining its food, in two long tentacula, which arise from the posterior part of the body, and are furnished

Medusa: A, under surface, showing the mouth in the centre, surrounded by the tentacula, and the ovarian chambers exterior to the origins of these; B, side view, showing the tentacula hanging down in their natural position.

external orifices. The animal may thus be compared, in some degree, to a *Sea-Anemone* detached from its base, and swimming with its mouth downwards. The membrane of the disc extends much beyond the stomach and ovarian chambers (which may be described

Berœ: a, a, tentacula; b, mouth; c, termination of intestine.

with a number of lateral filaments; these can all be withdrawn and folded into two cavities, excavated, as it were, in the substance of the body, and are easily unrolled when required for use.

A very common form of this class in some climates is the *Physalus*, known to sailors as the Portuguese Man-of-War. This is distinguished by its large air-bag, surmounted by a vertical membrane or crest, which usually floats above the surface of the water, and is acted upon by the gentle breeze, in the same manner as the little sail of the *Velella*. The animal organs placed below are very obscure in their character. No distinct stomach can be perceived; but the tentacula are dilated at their roots into chambers, of which each may perhaps be regarded as a digestive cavity. Some of the tentacula are very long, and hang down in the water to the depth of fifteen or twenty feet when the animal is floating. They possess considerable stinging power, and probably serve to entrap the food upon which the shorter tentacula, with their sucker-like extremities, then affix themselves, for the purpose of taking up nutriment by absorption. These *Acalephæ* have been termed *hydrostaticæ*, from the power they possess of rising or falling in water, by increasing or diminishing the bulk of the air-bag; but by what means they effect this change is not known. In some species, comprehended with the *Physalus*, in the order *Physograda*, several small air-bags exist, instead of a single large one. These are usually fixed to the same stalk, like currants upon their stem, and this rises out of the apparatus of tentacula, &c., of which the animal may be said really to consist.

The *Acalephæ* inhabit all climates, but the largest forms are to be seen in tropical seas.

Physalus.

CLASS XXII.—POLYPIFERA.

The animal character of the beings composing the class *Polypifera* was formerly doubted, as that of the Sponges is at present. The structures which they form, known as Corals, Corallines, &c., have often so much of the plant-like aspect, and sometimes also of an apparently woody structure, that, even in recent times, naturalists have been deceived into a belief in their vegetable nature.

Another popular error in regard to this group, is the attributing the formation of coral to insects, and the supposition that it is their habitation, constructed under the same circumstances as the comb of Bees, or the pyramids of the Termites. Now, the real fact is, that the masses of coral, madrepora, &c., as well as the sea-fans and other similar structures, with many smaller and more delicate ones, of which some are ranked among the sea-weeds, and others commonly known as corallines, are the skeletons of the animals by which they are produced, and are to be regarded as parts of the living structure, so long as the flesh which clothes or lines them retains its vitality.

If, for example, the stem of the common red coral be examined when clothed with its living flesh, its surface is seen to be scattered over with polypes, the structure of each of which bears some resemblance to that of the sea-anemone; but these, so far from being independent of one another, like so many sea-anemones attached to the same rock, are connected by a system of vessels which traverse the flesh, and bring them all into communication. Nevertheless, any one of these would live if detached from the rest, and would gradually produce others, until a new structure is formed, similar to that of which it was a part. Moreover, if a

piece of the gelatinous flesh be stripped from the stem, this will be competent to form both new polypes and a new skeleton.

Such compound beings, then, of which the polypes only form a part (like the leaves or flowers of plants), are not improperly termed *Polypifera* or *Polype-bearing Animals*. But there are many kinds of Polypes, which have no tendency to this kind of aggregation, and which are never found but in a solitary state. Such are the *Sea-Anemones*, and the *Hydra* or fresh-water Polypes. And various degrees of intimacy of connexion between the polypes of compound structures may be traced in different species; some of these will be hereafter noticed.

The class may be divided into four orders, characterised by four distinct types of structure: in each of these we shall find polypes existing almost or altogether independently of one another; and species closely allied to these, in which they are intimately associated. As the distinguishing characters of these orders cannot be understood without a knowledge of the structure of the polypes belonging to each, it will be better to proceed at once to the description of them, the amount of popular information on the subject being small. We shall begin with the one generally accounted the simplest.

Order I.—Hydroida.

The *Hydra*, or fresh-water Polype, is a minute animal, often found in great abundance, clustering round aquatic plants in stagnant pools.

It seems to consist only of a kind of bag, constituting its stomach, round the mouth of which is disposed a circle of long arms or tentacula, whilst the opposite end is prolonged into a foot, terminated by a kind of sucker, to which the animal attaches itself. The changes of form in this polype are very remarkable. The body has sometimes the shape of a long cylinder, whilst at others it is contracted into a sphere, the arms having shrunk alike into small projections around the mouth. This appearance is generally presented when the stomach is replete with food.

Hydra.

The *Hydra* is an extremely voracious animal; and, although little able to move from place to place, it secures an abundant supply of food by its long arms, which serve as so many fishing-lines. When any aquatic worm or insect touches one of them, it is entrapped by it, and other arms are speedily brought to its assistance; so that, by the simultaneous contraction of the whole, the prey is conveyed to the mouth, even if strong enough to make powerful resistance. Not unfrequently it can be seen to move about violently within the stomach for some little time; but the powerful digestive secretion speedily begins to act upon it, and its soft parts are dissolved, the hard ones being usually ejected by the mouth. When this solution has been performed, the fluid which results from it is seen to be distributed by a kind of circulation through the walls of the stomach and the arms.

Nothing in the history of the *Hydra* is so remarkable as its power of being multiplied by division, and of repairing the effects of other rough treatment. In regard to this, there really seems no limit. Not only can the body reproduce the arms, the mouth re-form the tail, and the tail the mouth; but, from a minute fragment, the perfect *Hydra* is reproduced, so that an individual cut up into forty or fifty pieces, will be converted into as many separate polypes. Two bodies, also, may be grafted together by the side, the tail, or in any other way; and monsters with two heads, two tails, &c., may be easily produced. It was, in fact, on account of this tenacity of life and tendency to reproduction as a con-

sequence of injury, that the name Hydra (after the fabulous monster of ancient times) was given to this little creature when first discovered about a century ago. The power of any one part to perform the functions of the rest, is remarkably shown by the fact, that the polype may be turned inside-out; so that what was before the lining of the stomach becomes the external integument, and *vice versa*, without its comfort being perceptibly impaired.

The Hydra is not known to subdivide spontaneously, however, but it propagates itself by a process resembling the budding of plants. A little knob first projects from the side of its body, this enlarges, and from the top of it are seen to spring a number of small processes, which are the arms. In the centre of these an opening appears, constituting the mouth of the young polype, which gradually assumes the form of its parent, and begins to catch prey for itself. Still, however, the cavity of its stomach communicates with that from which it was at first prolonged; but the passage is gradually narrowed, and at last obliterated. When quite independent, the young polype detaches itself from the parent, and has no further relation with it. Several of these buds may spring from the same polype at once, provided it be well supplied with food, and the temperature be warm; and a second generation may even show themselves upon the first, whilst still continuous with the parent structure.

The entire substance of the Hydra is soft, and no part seems possessed of greater firmness than the rest. In some other species, however, we find a tendency to the consolidation of the exterior into a kind of horny tube or sheath; and when a number of polypes are associated together, a compound structure is thus produced. In these compound structures the cells are connected by stems and branches, in the same manner as the buds of a plant; and through the base of each cell there is a canal lined by an extension of the lining membrane of the polype, and uniting with the channels which pass through the whole structure. Thus, all the polypes are brought into connexion with each other, and with the general mass or polypary.

These polyparies, formed by the association of hydra-form polypes, are among the most graceful and elegant of all the structures with which this class presents us. They are of minute size when compared with the massive productions of other tribes; and the uniform absence of stony deposit gives them a degree of flexibility which adds much to their gracefulness. There are few shores on which some forms of them may not be picked up. They are commonly mistaken for seaweeds.

The polypes, being enclosed in cells, do not share in the function of reproduction, for which a special apparatus is evolved. A set of horny vesicles (*b, b*), usually much larger than the polype-cells, are developed at intervals from particular parts of the stem and branches; and it is in these that the reproductive bodies or gemmules are formed. Each vesicle is provided with a lid, which falls off when the gemmules are mature and ready to swim forth; and the vesicle itself afterwards shrivels and drops away, like the seed-vessel of a plant that has shed its seeds. The whole of this process very much resembles the fructification of mosses, in the mode in which it is carried into effect.

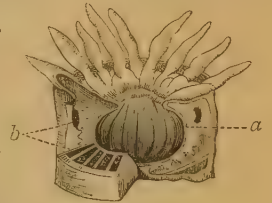

The forms of Polytipera allied in structure to the Hydra, compose an order which may be termed that of HYDROIDA, or Hydraform Polypes. This order is pretty uniformly distributed over the globe; not abounding more in tropical than in temperate regions. Scarcely any fossil remains of it are to be found.

Order II.—Helianthoida.

A common form of polype, apparently so different from the Hydra that the relationship between them would not have been suspected by an uninformed observer, is the *Actinia* or Sea-Anemone. There are probably no shores over the whole globe, except the very coldest, on which some species of this interesting creature are not to be found. The mouth is in the centre of the upper surface, and is surrounded by tentacula; and these are numerous and arranged in several rows. The under side forms a large sucker or disc; by this a very firm hold is taken of the rock or other surface to which the animal adheres. The stomach does not occupy the whole cavity of the body, but only the central portion; and the space between its wall and the outer integument is divided, by vertical membranous partitions passing directly from one to the other, into a number of radiating chambers, in which the germs of young *Actiniae* are produced, and sometimes nearly matured. The tentacula are hollow, and their cavity is continuous with that of these chambers; at the extremity of each is a small aperture, through which water is occasionally taken in, and then ejected with considerable force. This process seems to be of the nature of the action of respiration in higher animals.

Actinia seen from above.

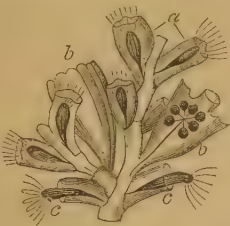

Section of Actinia: a, cavity of stomach; b, surrounding chambers.

The tentacula of the Sea-Anemone can be contracted in the same manner as those of the hydra, and they are furnished with a sort of sucker at their extremities, by which they can draw towards the mouth any substance which comes in contact with them. Although each seems weak in itself, the combined action of many is sufficiently effectual for maintaining an ample supply of food. These animals are extremely voracious. Not being able to move from place to place in search of particular kinds of nutriment, they are adapted to digest almost any which comes within their reach. Shell-fish and small Crustacea appear to be their usual diet. These are swallowed alive, in spite of their struggles, but are soon destroyed by the powerful solvent action of the juices of the stomach. The hard portions are ejected from the mouth; and, in getting rid of them from its stomach, the Actinia often inverts the lining of the latter through its entrance, so as almost to turn its body inside out.

The powers enjoyed by the Actinia of reproducing different parts which have been removed, and of multiplication by the division of its body, are nearly as great as those already described in the hydra. It may be divided either vertically or transversely, and each part will in time supply what was deficient, and become an entire animal. This reproduction has taken place in some instances from small fragments, but it does not appear that the same number can be reproduced by the subdivision of one, as in the hydra. We do not find here the same process of multiplication by buds, as in the hydra; but distinct germs, or ova, are formed in the radiating chambers which surround the stomach (hence called *ovarial* chambers), and from these, as from the eggs of higher animals, new beings like the parent are produced. The development of them may take place whilst yet within the body of the parent; and thus, as the young ones pass out from the mouth, it appears to cast them up from its stomach.

The sea-anemone is not the only solitary polype possessing the kind of structure which has just been de-

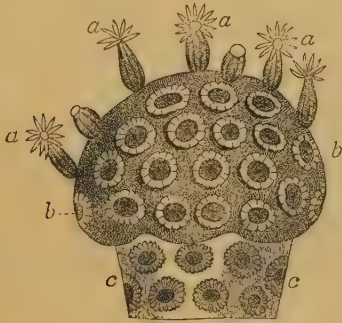

Portion of Sertularia: a, a, polype-cells with polypes; b, b, ovary vesicles.

scribed. Several other species exist, in which the same type is presented with various modifications.

There are some among them which form a stony deposit in the substance of their base, and in the membranous partitions between the radiating chambers. Of these one small species inhabits the British seas; it belongs to the genus *Caryophyllia*. A very beautiful coralline formation of this description is that produced by the *Fungia*, an animal allied to the sea-anemone, and inhabiting only tropical seas. It consists of a thick round plate, sometimes several inches in diameter, from one surface of which arise thin vertical plates, radiating very regularly from the centre to the circumference. This is, in fact, a single cell of a large solitary polype, and from it the structure of other coralline masses will be understood.

The cells of such solitary polypes are not always round, but are sometimes very much prolonged in one direction, so that the depression in the centre, marking the place of the mouth, towards which all the radiating plates are directed, becomes a long groove. These stony masses contain a considerable quantity of animal matter, by which the particles of carbonate of lime are glued together; and when a sufficiently fresh specimen of a stony coral is submitted to the action of an acid which dissolves these, the animal substance will retain its form.

Mass of *Astrina Viridis*:

a, a, expanded polypes; b, b, polypes withdrawn into their cells; c, stony mass uncovered by flesh.

The number of stony corals formed by the compound Polypifera is very great; and, of the more massive kinds, a large proportion belongs to this order. Those which are to be ranked as the skeletons of animals allied in structure to the sea-anemone, are distinguished by a character very easily recognised. In each cell, however minute it may be, the arrangement of radiating plates, described in the *Fungia*, is seen; and from the presence of these thin plates, or *lamellæ*, the whole of this group of corals and madrepoes have been designated as *lamelliform*. A lamelliform coral is, then, always formed by a polype similar to the sea-anemone (or *actiniform*); and thus, by attending to the mode in which the growth of the coral depends upon the structure of the animal, we obtain a valuable character, on which we can always rely.

The individual polypes belonging to such structures are connected by a gelatinous flesh enveloping the whole, which seems to answer to the membranous pith lining the stems of the compound Hydroida. It is by this flesh, rather than by the polypes themselves, that much of the stony mass is deposited, as may be seen by examining many species in which the intervals between the cells are considerable. The variety of aspect which these masses present is very great, but there is little difference, so far as is known, in the structure and habits of the individual polypes, which form part of the beings in their living state.

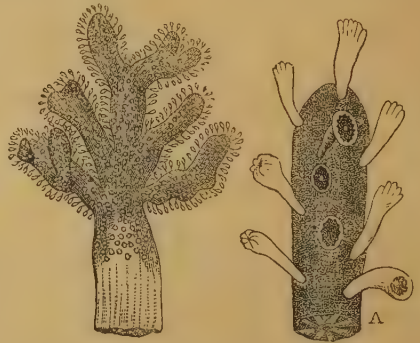

None but stony corals are formed by Polypifera of this order; but there are many of that description

which do not belong to it, of which we shall hereafter speak. However, it is to this order that the greater part of those species belong which are concerned in erecting the massive structures known at present under the names of coral reefs and islands, as well as those which appear to have existed in still greater amount in former epochs of the earth's history, and to have given origin to the greater part of the limestone rocks which constitute so large a proportion of the crust known to us. This order may be denominated that of *Actiniform* Polypes, from the general resemblance of the animals composing it to the sea-anemone; or *Helioanthoida*, from their similarity in aspect, when expanded, to the sun-flower.

Order III.—Asteroida.

The next order of Polypifera is one which brings us nearly to the form of the Sponge. In the compound groups we have been last considering, the polypes form an important part of the general structure, and in some instances each may be regarded as existing almost for itself alone, even where many are united by the connecting fleshy matter. But in the group to be next treated of, the polypes seem quite subordinate, and the general mass seems to have (as in the sponge) much more of the character of a single individual. In these structures we observe, too, that the hard basis or skeleton is seldom so distinct from the living tissue as in the lamelliform corals, the two often passing into each other by almost insensible gradations. The density of the skeleton varies considerably in the different species. Sometimes it is of a spongy character, as in the *Alcyonia*; sometimes of a stiff horny texture, as in the *Gorgonia*, or Sea-Fan; and sometimes of a stony hardness, as in the Red Coral.

The *Alcyonia* are found abundantly on many parts of the British shores, and are known to fishermen by

Alcyonium:

A, portion enlarged, showing the polypes.

the names of *dead-man's-hand*, *sea-fingers*, *sea-paps*, &c., from their flabby texture, and the peculiar forms they present. Their structure is spongy, but they have usually a more distinct envelope than the true Sponges, and this has sometimes a leathery character. Their interior is traversed by a series of canals, which ramify and inscuate with each other; and, on cutting into the mass, it is observed that nearly the whole tissue is composed of a network of these passages, separated by the animal fibrous tissue, which is sometimes condensed into a fabric of considerable firmness. The large canals have no direct external opening, however, but they terminate in prominences of the spongy mass, from which the polypes protrude.

The polypes themselves have some resemblance to the sea-anemone, but they are usually much smaller and of more delicate structure. There are, however, some important differences, upon which the character of the order is founded. The tentacula, instead of being numerous, and arranged in several rows, are only eight

in number, and form one circle. They are broad, and almost leaf-like, instead of being round and slender. The mouth is situated in the midst of them, and leads to the stomach, which occupies the centre of the body; around the stomach are the *ovarial chambers*, separated by radiating partitions, but only eight in number. The stomach opens into the canal upon the end of which the polype is placed, and all the fluid which enters the mass appears to be taken in through these mouths. The ovarial chambers also communicate with the canal beneath, indeed they may be said to be a continuation of it, for the partitions between them are prolonged downwards into the canal, forming plaits or folds of its lining membrane, in which the ova or germs are developed; so that these are produced from the general mass rather than from the polype, and the whole structure may be regarded as a higher kind of Sponge.

The polypes are capable of being drawn entirely within the protuberances on the surface of the *Alcyonia*, and even these projections become flattened when the animals are in a state of great contraction. In this condition they are often left by the tide, and if then placed in a glass of clear water, their gradual expansion may be watched. The protuberances from the surface first show themselves, and the polypes, one by one, appear at their summits, and slowly expand their tentacula, until the whole surface appears covered with delicate blossoms. The entire mass then not unfrequently swells to twice or thrice its original size. If any one of the polypes is irritated, it shrinks into its hiding-place, but those near it are not affected. If the irritation of the part be prolonged, however, those in the neighbourhood gradually show themselves influenced by it, and draw themselves in; and in this manner the whole mass may be ultimately affected. The same effects, however, may be produced by irritating a portion of the spongy substance intermediate between the polypes. From this it is evident, that sensibility to impressions is not confined to the polypes alone, but that the whole mass must be regarded as possessed of animal properties.

The *Alcyonia* grow in the same circumstances with Sponges, and their correspondence is further shown by the existence of crystals of silex in their tissue, which are not found in other polype-structures, the earthy matter in these being entirely calcareous. The different species of the *Alcyonia*, like those of the Sponges, may be distinguished by the form of the spicula preserved in the skeleton.

In other forms of this order we find the skeleton, or firm support, in a more concentrated form. Thus in the *Gorgonia*, a beautiful framework of horny matter, consisting of a stem and a minute network of branches, occupies the centre of the structure; and this is clothed with a soft flesh, through which the channels pass that connect the polypes together. This flesh is covered with a firm skin, in which a great amount of earthy crystals is deposited, so as to form a crust; and in this are the hollows or cells by which the polypes are protected. In the dead structures, with which we are familiar under the name of *sea-fans*, the dark horny flexible stem is seen to be covered in many parts with a brittle crust, often brightly coloured, which can be scaled off it and crumbled to powder. Between the two, in the living state, the fleshy coat existed; the inner part of it being in contact with the exterior of the horny stem, which was then soft and scarcely distinct from it, whilst the exterior part was consolidated by the earthy matter into the firm integument.

In the *Isis*, we find less stony matter on the outside of

the flesh, but a deposition of it at intervals in the stem, which thus obtains a jointed character, being flexible at the points at which the horny matter has not been consolidated. And in the *Red Coral*, the entire stem is converted into a very firm stony axis, which presents no indication of polype-cells, these being excavated only in the flesh that clothes it. The *Pennatula*, or Sea-Pen, is an interesting species belonging to the same group, and in some respects resembling the *Red Coral*; it has a stony axis, but this is flexible at the extremities; and it is not attached by a solid basis, but is carried about by the mercy of the waves. From the central axis, which is nearly straight, a regular series of lateral branches passes off on each side, like the barbs of a feather; and on these the polypes are situated. By the simultaneous movements of their tentacula, the animal (if it is to be called one) seems to have some power of directing its course, if not of propelling itself through the ocean. A small species, which is luminous at night, inhabits the British seas.

Single Polype of Pennatula.

There is one species in this order which differs from all the rest in the consolidation of the exterior rather than of the interior tissue; so that a stony tube is formed instead of a central stem. This is the *Tubipora musica*, of which the skeleton is known as Organ-pipe Coral. The polypes are not here connected by any system of vessels or uniting flesh; each lives for itself alone, but a number (probably all produced from the same stock, and by offsets from each other) unite for mutual support in one structure. Each polype has a cylindrical form, and its exterior membrane is progressively consolidated into a stony tube, which is thus gradually increasing in length by new deposits at its upper end. At certain intervals the soft membrane (which is always projecting beyond the mouth of the tube) is flattened down into a sort of collar, which is consolidated likewise; and the collars of the neighbouring tubes coming in contact with one another, form a sort of floor or shelf, which greatly strengthens the mass. After this collar is formed, the tube is continued as before for another period, when a similar floor is again produced by the simultaneous action of the numerous polypes composing this beautiful structure.

To this order the term of *Alcyonian* Polypifera (from the name of one of its principal groups), may be conveniently applied; it is also known by the designation of *Asteroida*, from the star-shaped form presented by the tentacula when expanded. Its most luxuriant kinds are natives of tropical seas; thus the *Alcyonium poculum*, or Neptune's cup, which abounds in the neighbourhood of Singapore, is one of the most bulky species at present existing. But the smaller tribes abound in our own seas. No massive stony polyparies are formed by the animals of this order.

Order IV.—Ascidioidea.

The last order of Polypifera far surpasses all the rest in the complexity of its organisation; although so little distinguished from them in external form, that a cursory examination would not reveal the points of difference. In fact, many of the species belonging to it have been associated with the *Hydraform* Polypes, by naturalists of eminence; and it is only by means of a high and clear magnifying power that their true structure is capable of being ascertained. The stony character of the polyparies formed by others, has led them to be grouped with the *Actiniform* Polypes; and it is only within a very recent period that opportunities have been afforded for that examination of their living condition, upon which alone reliance can be placed.

The polypes of this order seem more independent of one another than they are in the associated groups of the others; but they are not known to exist in an absolutely isolated condition. A species lately discovered on the

Pennatula.

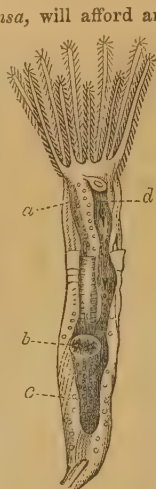

British shores, the *Bowerbankia densa*, will afford an excellent illustration of the structure of the separate polypes. These arise like buds from a sort of creeping stem, which connects them all, and which has the power of extending the structure by its own growth; but no communication has been observed between the interior of this stem and the stomachs of the polypes, like that which exists in the Sertularia. Each is enclosed in a horny transparent sheath, the upper part of which is so flexible, as to be capable of being drawn inwards by the action of muscles, thus closing the mouth of the cell.

The polype itself has, when protruded, the general form of the hydra; the mouth being surrounded by ten long and slender tentacula. There is this important difference, however, that, in the *Bowerbankia* and all the other polypes of this order, the arms are fringed with cilia or little hair-like filaments; whilst in the *Hydraform* Polypes no such appendages exist. This difference is more important than it would at first sight appear, being connected with the whole economy of the animal. The hydra only obtains its food by grasping with its arms that which comes within their reach; but, in the animals at present under consideration, the rapid vibration of the filaments, which seems to take place at the will of the polype, produces currents in the water, by which a regular stream is brought to the mouth; and this stream contains many nutritive particles, from which a selection, adapted to the highly-organised digestive apparatus, may be made.

The mouth opens into a wide tube, which may be regarded in the light of the œsophagus or gullet of higher animals; and this terminates, at its lower end, in a narrow orifice leading to a globular cavity, which seems analogous to a gizzard, having thick muscular walls, lined with tooth-like processes. Here the food seems to be ground down, before being transmitted to the true stomach, a much larger cavity, situated below it, in which the process of digestion takes place. From the upper part of the stomach, not far from the first opening, an intestinal tube passes off by a distinct orifice; and this terminates on the outer side of the ring to which the tentacula are affixed.

The whole process of digestion may be distinctly watched in this beautiful little animal. The food obtained by the motion of the cilia passes into the mouth, and is propelled downwards to the first stomach or gizzard, by the successive contraction of the walls of the tube, as in the highest animals. After being subject to a brief trituration there, it is passed onwards to the principal stomach, where it remains a considerable time for digestion, being sometimes regurgitated, for a second trituration, to the gizzard. The matter to be rejected does not return, as in the lower Polypifera, by the mouth, but passes, in the form of little granules (no large substances being ever swallowed), into the intestine, where it accumulates into small pellets, which are gradually propelled to its outlet by the successive contractions of the tube. When they have been ejected from it, they are carried to a distance by the reflux of the current, which is constantly being driven by the action of the cilia to the mouth. No nervous system can be detected in these animals, yet its presence may be inferred from the existence of distinct muscular structure, of which different parts have to be put in action at the same time.

There is considerable variety in the structure of the Polypifera which have been associated into the group of which this is a specimen, some being more and others less complex; but they all agree in these two essential

Bowerbankia: a, œsophagus; b, gizzard; c, stomach; d, orifice of intestine.

points—the possession of a second external orifice to the digestive cavity, and the presence of cilia on their arms. By these they are distinguished from all the other Polypifera. The latter of these characters has been embodied in the term *cilio-brachiata* (ciliated-armed), which is very appropriate. They have also been called Bryozoa, from their fancied resemblance to mosses; and Ascidioda, from their affinity to the *ascidiæ*, a group in the lowest class of Mollusca.

The polyparies formed by the animals of this group differ considerably from each other in the structure and arrangement of their parts. Frequently they have but a horny texture; sometimes, however, stony matter is deposited in the cells, and fills up the interspaces between them. A very common kind of compound structure is the *Plustra*, which grows in flat expanded surfaces, often encrusting sea-weeds and other marine bodies, but sometimes without any such attachment. This may be picked up on almost any of our shores; it is often mistaken for a sea-weed, but is distinguishable from it by its greater crispness and firmness of texture, and by the cells which may be observed to cover its surface. These cells are extremely minute, and are set closely together, so that a very large number, each when alive containing a polype, exists in each specimen. The polypes of this order are also reproduced by the formation of gemmules, somewhat resembling those of Sponges and Sertularia, but endowed with greater activity, and with apparently greater power of directing their movements. These are developed from the inner membrane of the cell, and gradually increase so as to fill up its cavity, and to cause the death of the contained polype. When they at last escape, they swim, like animalcules, with a great variety of movements; and seem to have a perfect control over the vibrations of the cilia with which they are covered, and by which all their motions are produced. When they at last fix themselves, they spread themselves out each into a gelatinous film, in the substance of which the outline of cell soon shows itself, and the polype, with all its complex parts, is developed by degrees. To this first-formed cell others are soon added.

The Polypifera of this order seem to attain their full development under a less constantly elevated temperature than that required by the *Helianthoida*. Stony corals are formed by them in many seas of the temperate zone, and the more delicate species abound on our own coasts. This fact is interesting when we compare the fossil with the recent corals, as will be presently done.

When we consider the vast extent of the coral formations, which are at the present time effecting a change on the surface of the globe that has been a fertile theme of astonishment and admiration, we cannot but be struck with the enormous amount of animal existence that must be concerned in producing them. Much error has prevailed on this subject, however; and in some points exaggerations have been produced through superficial observation. But here, as in almost every department of nature, the truth, as disclosed by a more careful examination, is far more wonderful than the showy covering in which the common love of the marvellous may have enveloped it.

It is generally stated that the coral masses, forming reefs or islands, are built up from the depths of the ocean. This is not strictly true; for it is well ascertained that none of the species which form the massive stony structures of which these are composed, can exist at a greater depth than from 80 to 120 feet. It is evident, then, that supposing the relative level of the land and sea to have been always the same as at present, these coral structures must be based on the summits of submarine mountains or ridges of hills, which rise from the bottom of the ocean, like corresponding hills and ridges upon the dry land; since deep water is almost always to be found in their neighbourhood. This is probably true to a certain extent. There is reason to believe that solid rock exists at no great depth beneath

the surface of some of the islands; and there are many in which it forms part of them, a cone of rock rising out of the water, encrusted with a terrace of coral. Moreover, it may be stated as a general fact, that there is no part of those seas in which the temperature, depth of water, and other circumstances, are favourable to the operations of the coral-polypes, in which they are not constantly at work; and thus channels are being constantly rendered narrower and less deep, and harbours are being blocked up which were formerly accessible. But this takes place with less rapidity than is generally imagined.

The coral islands of the Pacific and Indian Oceans constitute a large proportion of the groups with which that vast area is scattered. In some instances they are considerably elevated above its level; but in general their surface is but little raised above it. As the polypes do not build above low-water mark, it does not become at once apparent how even this elevation is attained. It is to be remembered, however, that in the tropical ocean there is an almost constant succession of waves driven by the trade-wind from east to west. These, dashing against the windward side of the islands, break off blocks from the masses of coral, which they cast upon the summit. An accumulation of these blocks, consolidated by smaller fragments, and by the sand resulting from their constant friction, gradually produces a firm rocky substratum. The surface of this, decomposed by the atmosphere, forms a sort of chalky soil, which is well adapted to the growth of many kinds of plants; and their seeds being drifted by the sea, or brought through the air by birds, take root in it, so as speedily to cover the island with a luxuriant vegetation. The growth and decay of successive crops gradually covers with a thick layer of mould the previous chalky soil; and this affords support to the most beautiful kinds of tropical plants, which the humidity of the insular atmosphere causes to flourish to a degree rarely seen on continents.

Several of the coral islands take the form of rings, containing large basins of water communicating with the sea, which are termed lagoons. These were probably erected on the craters of submarine volcanoes; of the existence of many of which, beneath the Pacific Ocean, there can be no doubt. They first rise to the surface in the form of circular reefs; the windward side is gradually raised above the sea-level by the process already described; but an opening usually remains at the leeward side, through which the water that washes into the central basin may flow out. As the whole ring is gradually elevated, however, the source of this overflow diminishes, and gradually ceases; the leeward channel is filled up by the growth of coral, and the lagoon is cut off from the sea. This basin, also, is at last filled up by the accumulation of fragments of coral, and by the growth of the more delicate species in its interior; and at last one nearly uniform surface is produced.

There is reason to believe, however, that in many instances the coral extends to a much greater depth beneath the surface than that in which the animals are known to live; and the question then arises, in what manner was it formed? A careful examination of the islands of the Pacific Ocean shows us that many of them, which rise considerably above the surface, are entirely composed of coral. Now, as the coral-polypes never build above the level of the sea, it is evident that some subterranean movement, probably of a volcanic nature, must have lifted these islands from the bed of the ocean. In some instances the height at which coral may be found is very great—not less than eight or nine thousand feet. It is not improbable, then, that as the bottom of some parts of the ocean is rising, that of others should be falling. If a coral island had been originally formed in the usual way, and had then gradually sunk in the water, the polypes would have continued to build it up to the surface; and thus almost any amount of thickness may be produced, by a corresponding slow subsidence.

One of the most extraordinary coral growths known, is the barrier-reef which stretches along the shores of

New Holland, at a distance of usually more than a hundred miles from the coast. This is above a thousand miles long; and for several hundred miles has no break wide enough to give passage to a ship. It is scarcely conceivable that a submarine ridge of hill should exist, a thousand miles in length, and approaching every where within one hundred feet of the same elevation; for such a ridge is nowhere seen on the dry land. But it is easy to account for this remarkable structure, if we suppose that the ridge was formerly more or less elevated above the surface; and that its different parts gradually became encrusted and capped with coral as they were submerged, after which the growth would continue upon the same parts, until the whole, being thus depressed and covered, became the continuous mass which is now witnessed. That such depressions are taking place in some islands of the Pacific, is a fact substantiated, not only by the traditions of the natives, but by observations made since they have been visited by Europeans.

There are many instances in which the coral structures of comparatively recent origin have undergone a metamorphosis, which causes them to lose in some degree their original aspect. Large masses, when long exposed to the air, become changed into a solid, often somewhat crystalline, rock, in which the traces of organic structure are very indistinct, and with which the *mountain* or *secondary limestone* closely corresponds. This is observed in the Bermudas. Moreover, the coral sand often becomes agglutinated, by the percolation of water through it, into a very hard stone; it is in such a mass that the human skeleton, found on the shore at Guadeloupe, and now placed in the British Museum, is imbedded. This stone, when minutely examined, is seen to consist of a number of rounded grains, cemented, as it were, together; and it closely resembles the rock known to the geologist as *oolite*. Further, where shallow water exists around coral islands, the bottom is found to be covered with a layer of white mud, which is formed by the decay of the animal matter that held together the particles of carbonate of lime in the stony corals, and these are consequently set at liberty in a finely-divided state, and fall to the bottom in a form which, if dry, would constitute *chalk*. Thus we may trace, very distinctly, the mode in which the three principal kinds of limestone rocks may have taken their origin in coral formations.

Now, the mountain limestone, as it is termed—a rock very abundant in Britain, extending over large areas beneath the coal-fields, and sometimes exhibiting a thickness of nearly 3000 feet—is in some parts evidently composed of accumulations of shells, stems of encrinurites, &c. But in many others, the remains of corals are very distinct; and these are so blended with the neighbouring rock as to make it appear probable that the latter also was once in the state of coral, but was gradually changed by the process just described. Further, the collections of other animal remains are just such as we should expect to find on the margin of a coral reef or island existing at that epoch; and a similar process of fossilisation is taking place on the shores of those existing at the present time; the imbedded series of animals only being different. The great thickness of the beds of this rock may be very well accounted for, in the same manner as the depth of the coralline masses of recent formation.

There are observed, in rocks of more recent formation, appearances which still more clearly indicate that they too were originally formed by coral-polypes. These are often found only within narrow limits, as if they had been reefs or islands of small size. Thus we find a stone called coral-rag in Oxfordshire; and very distinct coral beds in the crag of the eastern coast of England. It is interesting to remark, that the remains of coral which are found in the older limestones, all correspond with those at present abounding near the equator, and exhibit the *lamellar* character; whilst they are gradually replaced in the newer strata by species more allied to those at present existing in tempe-

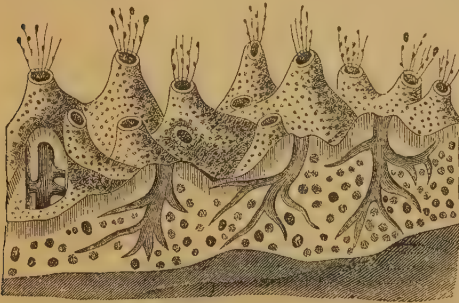

rate climates. This is one of the many facts which tend to prove that this part of the earth had at some former period a much higher temperature than at present.

We see, then, that vast as are the works of the existing species of this class, they are probably far surpassed by the accumulations of former ages, which constitute, in some form or other, a large proportion of the solid rocks of our terrestrial surface. And thus we see the exemplification of a principle which has frequently come under our notice—that in the economy of Nature nothing is insignificant; and that the most gigantic effects may be produced by the multiplication even of the humblest among the living inhabitants of the globe.

CLASS XXIII.—PORIFERA.

Of all the beings usually known under the designation *Zoophytes*, the *Sponges* and their allies, constituting the class *Porifera*, appear to have the best claim to the title; since they present so complete an admixture of the characters of plants and animals, that it is difficult to say to which division of the organised world they properly belong. Like plants, they are fixed to one spot during the whole of their lives, subsequently, at least, to their first development; they seem to possess no sensibility, for they can be torn or wounded in any way without showing by their movements any indication of being affected by the injury; and they do not appear to have that power of executing voluntary motions which must be regarded as the distinguishing characteristic of animals. On the other hand, they present a structure which is not analogous to any thing found in plants, but is similar to that of beings undoubtedly belonging to the animal kingdom; with these beings they are connected by intermediate forms, presenting a regular gradation of increasing complexity of structure and variety of function; and there are certain movements, both in the adult and in the undeveloped *Sponge*, which are more analogous to those seen in higher animals than to any observed in plants. On the whole, however, the evidence for the animal character of the *Sponges* seems to preponderate; and they will be accordingly considered here. Still there is no doubt that, if they are included in the Animal Kingdom at all, the lowest place in the scale should be assigned to them.

The common *Sponge* is a sufficiently characteristic form of the class, to serve as the foundation of a general

Section of Living Sponge.

account of the structure which prevails in it. On looking at its exterior, we observe that it is covered by a number of closely set and minute orifices; and that larger openings are disposed at intervals among these. The former are termed *pores*, the latter *vents*. On cutting into the substance of the sponge, it is seen to consist of a sort of network of filaments, interlacing together in such a manner as to leave large channels and spaces of various forms, which communicate with each other. The large channels terminate in the vents; and, on tracing any one of them into the substance of the sponge, it is seen to divide and send off ramifying branches, which at last lose themselves in the spongy network that lies around them; and this communicates with the pores on the external surface.

The interlacing fibres, of which the walls of the large canals, and the spongy tissue between them, are alike composed, entirely consist (in the common sponge) of a sort of horny animal matter, as is shown by burning a small portion of them. But in other species we find *spicula*, or needle-like crystals, of siliceous or of carbonate of lime, disposed amongst these, giving to the structure much greater firmness, but depriving it, more or less completely, of that elasticity which is so useful in the common sponge.

The substance known as *sponge* is, however, but the skeleton of the being; when alive, this fibrous network is clothed, within and without, by a thin gelatinous substance, very like the white of an egg. This lines all the passages, and covers the exterior; but it drains away when the sponge is removed from the water. In this the peculiar vital endowments of the being appear to reside. These are manifested, not only by its slow but regular growth, but by a curious circulation of fluid, constantly taking place within the mass. When a sponge is examined in its living state, beneath the water, a constant current is seen to issue from the vents; being made evident by the disturbance of the water, and by the movement of particles floating in it. It may also be ascertained that a constant flow of water takes place inwards through the pores; for small solid particles upon their edges are occasionally seen to be sucked in. No intermission can be detected, during the life of the sponge, in these currents, which evidently have for their object to convey the nutritive matter contained in the water into the interior of the mass, and also to carry off the particles which are to be excreted, since thin films detached from the living tissue are seen to pass out from the vents along with the fluid ejected from them.

The relative position of the *pores* and *vents* differs much in the different kinds of sponge. Sometimes all the former are on one side, and the latter on the other. Not unfrequently the vents are placed on the summit of little conical prominences, which look like craters of a volcano; and the stream issuing from them, when seen under a microscope, may be likened to a miniature eruption. Sometimes the sponge assumes the form of a hollow cylinder, which hangs at one extremity from a rock; the pores are all upon the exterior surface, whilst the vents open into the interior cavity, and their united stream rushes out with considerable energy from the lower end of the cylinder.

Sponges may be multiplied, like plants, by artificial division, each portion becoming a new individual, but it does not appear that this is their natural mode of increase. They propagate by detaching little round gelatinous bodies, termed *gemmules*, from their living tissue; which in time develop the original form of the parent. These are produced in the network between the large canals, into which they find their way; when mature, they pass out of the vents in the current which sweeps through them, and by which they are conveyed to a distance. In these gemmules a peculiar motion, like that of animalcules, may be seen for some time; they swim hither and thither; at last they fix themselves, and begin to deposit the horny or earthy particles which are to form their skeleton; and the system of canals gradually shows itself in their substance. When once they have fixed themselves, they seem to lose all power of further movement, and remain during the rest of their lives attached to the same spot.

Some kinds of sponges are found on almost all shores; and some frequent deep water, whence they can only be obtained by dredging. It is in this manner that the common sponge is procured from the Mediterranean, the Grecian archipelago, and the other localities it frequents. Sponges are not confined to the sea, however; for there is a species which inhabits fresh water.

With the notice of this group we appropriately close the subject of Zoology.

ACCOUNT OF THE HUMAN BODY.

THE external appearance of the human body is necessarily familiar to all. Its internal structure, however, and the manner in which its different functions are performed, are not understood as they ought to be by the generality of people. The more fully that we comprehend the structure of our frame, the more attentive shall we be to its preservation in a state of health, and the more capable of accomplishing that all-important object. The present treatise will therefore be devoted to a description of the human body, in language as popular as the subject will permit, and as concise, at the same time, as possible.

Zoological science places the human being in the class of *Mammalia*, or suck-giving animals, and in the order of *Bimana*, comprising the two-handed creatures of that class. An erect posture is the peculiar characteristic of man, and it is one which gives to his aspect that dignity becoming his high place in creation. By the adaptation of an erect structure, also, his hands are left disengaged, and ready for the numerous operations to which he is inclined by his judgment or urged by his wants. His general stature is between five and six feet. A combination of hard and soft parts forms the material of his frame, the soft portions being arranged, generally speaking, upon and around the more solid parts of the structure. These latter parts consist of a beautiful framework of bones, termed the *skeleton*, which naturally occupies the first place in our description. *Muscles and tendons*, which are the organs of locomotion; the *brain and nervous system*, or organs of sense, feeling, and intellect; the *lungs*, for respiring the air essential to the maintenance of the principle of life; the *stomach and digestive organs*, for the supply of nourishment; the *heart, blood-vessels, and absorbents*, for the circulation of vital fluids through the body;—these and other important parts will fall to be described after the solid framework on which they rest has received its due share of our attention.

The skeleton comprehends three main divisions, the head, trunk, and extremities, which consist, in all, of 254 bones, joined together in a manner combining great strength with ease and freedom of motion. The whole of the bones are composed of nearly the same materials, namely, earthy matter, chiefly lime, and gelatine or animal glue. The lime gives them hardness and solidity, while the animal matter cements or binds them together, and renders them not easily broken. They differ to some extent in solidity and weight. A middle-sized adult skeleton, weighed all together, ranges between 160 and 200 ounces, or from 10 to 13 pounds avoirdupois. The heaviest bones in the body, in proportion to their size, are the bones of the skull, extremities, and pelvis, or under part of the trunk. Their surface is for the most part smooth, and the interior, beneath a cake or coating of more condensed substance, is porous and spongy. The bones of the extremities are hollow, like pipes, by which arrangement they are rendered at

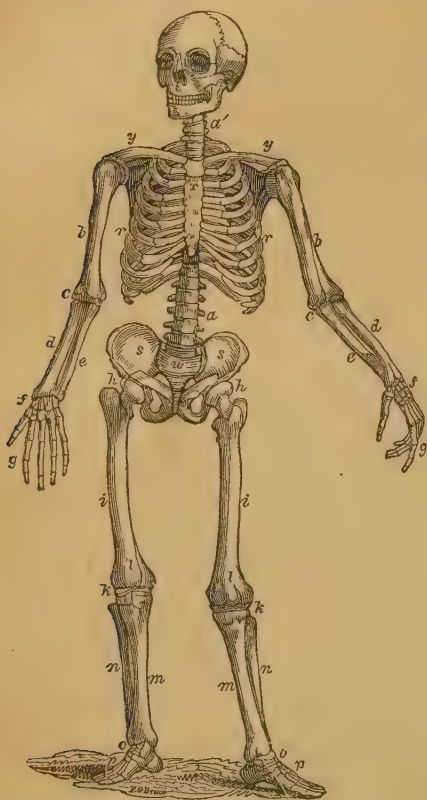

once light and strong. The marrow is contained in the internal cavity. Compact as they are, the bones are nevertheless pervaded by blood-vessels, which, indeed, are essential to their vitality.

The crown or summit of the osseous fabric is occupied by the cranium or skull, which is composed of eight bones, the *frontal*, the *occipital*, and the two *parietal*, constituting the greater part of the outward skull, before, behind, and laterally. The two *temporal* or temple bones, on the under part of each side, and the sphenoid and æthmoid bones, placed at the base of the skull internally, are the remaining bones of the head. The union of these bones is remarkably firm and strong in the adult being. In some cases, the osseous plates are joined by serrated or ragged edges, like the teeth of a saw. In other instances, they overlap each other, like the ridge of a house; the arrangement, in each case, being precisely the one best fitted to ensure strength and stability in the particular part. Altogether, an arch of the most powerful kind is formed, for the safe protection of the important organ within, the *brain*. The bones of the face, situated below and before the cranium, are numerous. Among the facial bones are reckoned the two upper *maxillary* or jaw bones; two *malar* or cheek bones; two *nasal* or nose bones; two small bones, attached to the nose internally, called the *turbinated* bones; two *palate* bones; the two *lacrymal* bones, situated in the orbit; the *vomer*, or ploughshare bone, forming a part of the basis of the nose; and the single lower jawbone, or *maxillary* bone of the lower jaw.

The bones of the skull and face rest upon the top of the spine or backbone, which consists of twenty-four separate pieces, called *vertebræ*, firmly and curiously jointed the one into the other. The column of the spine is curved in several places, the most prominent being a curve forwards near the middle of the back. Seven of the *vertebræ* are called *cervical*, twelve *dorsal*, and five *lumbar*, from being situated respectively in the neck, back, and loins. Each *vertebra* has various projections and depressions, to admit of a firm union with those adjoining it; and, by the junction of the whole, a long hollow or canal is made, for the reception of the spinal marrow. In the annexed figure, the upper part of the vertebral column is marked *a*, and the lower *a*. The second of the *vertebræ* of the neck sends upwards a projecting pinion or tooth, which is received into a corresponding depression in the one above, thus forming the pivot upon which the head turns.* The bones of the spine rest upon the *pelvis*, *s s*,

* A ligamentous band keeps the tooth-like projection of the second *vertebra* in the depression of the first. Nothing can better show how completely our life, during every instant of its duration, depends on the maintenance of every single part, however minute, in order. If this ligament, scarcely thicker than strong paper, were to give way, instant death, from pressure on the spinal marrow, would ensue. A porter, carrying a burden, dropped down dead. On examination, no cause of death could be

a hollow, basin-shaped cavity, which is formed of two large bones, and composes the lower part of the trunk,

giving to it firmness and stability. The spine rests on it by means of the *sacrum*, *w*, a series of five imperfect vertebrae, consolidated into one piece in advanced life, which sink like a wedge between the pelvic bones of each side. The sacrum terminates in a loose osseous peak, called the *os coccygis*. The strong, hollowed, cup-like bones of the pelvis, are marked by large round depressions on the outer and under surface of each, which form sockets for the two upper bones of the leg. At the top of the spine, immediately below the vertebrae of the neck, are situated on each side the collar-bones or *clavicles*, *y y*, which are long and narrow in shape, and pass in a semicircle or arch from the front of the chest backwards, or, in other words, from the *sternum*, *x* (breast-bone) to the top of the shoulders. On the back of the ribs, at each side, lie the shoulder-blades or *scapulae*, which are thin flat bones, of a triangular shape. They rest loosely on the back, having scarcely any attachment except by muscles to any of the neighbouring bones. By this means they have a free and easy motion, and also communicate the same property in part to the arms, the upper bone of which is attached, on each side, to the scapula. A very small cavity in the latter bone admits the round ball-like head of the humerus, giving to it the most unconfined play of movement, whether of a rotatory kind, upwards, downwards, or sideways. Nothing can be more beautiful than the whole arrangements for permitting the arm to perform the multifarious motions which man requires from it. The *humerus*, a single bone in each arm, *bb*, cylindrically shaped, is united at the elbow-joint, *cc*, to the two bones of the fore-arm, termed the *radius*, *dd*, and *ulna*, *ee*. One of these, the ulna, is attached to the humerus by a hinge-joint (like that of a common door), while the

found, till this apparently petty ligament was noticed to have given way, producing instantaneously the fatal result.

radius is connected to the same bone by a round button-like head, which, being slightly concave, receives a projecting knob of the humerus, and admits of rotatory movements being performed by the lower part of the arm. These peculiarities of structure are essential to the free use of the hand. At the wrist, the position of the radius and ulna is in some measure reversed, the radius forming with the *carpal* bones, *ff*, a joint like that of a door-hinge, while the ulna is in a measure left loose. The carpal or wrist bones are eight in number. They are of small size, and lie in two rows, being jointed together in a manner that combines great strength with a certain degree of mobility. In the direction of the points of the fingers, they are united with the *metacarpal* bones, forming the palm of the hand, and to which the *phalanges*, *gg*, or finger bones, are attached. Each finger has three bones in it; the thumb has only two.

As has been said, the bones of the pelvis, on each side, are marked by deep cup-like concavities, which receive the heads of the thigh-bones, *hh*, *ii*, (*femur*) the upper bones of the lower extremities. As was required by the different nature of the purpose to be served, the ball-and-socket joint of the leg is much stronger than that of the arm, and permits of much less freedom of motion. The *femur* or thigh-bone is a rounded cylindrical bone, terminating at the knee in a connexion with the *tibia*, *m*, the principal bone of the inferior part of the lower extremity. The knee-joint is a hinge one, but permits of a slight rotatory motion when the leg is bent. The tibia has a smaller bone, the *fibula*, *nn*, placed by its side, and over the knee-joint is situated a small bone called the *patella*, *ll*, or knee-pan, to which the principal muscles that move the joint are attached, and which serves to protect the parts against injury. The tibia and fibula form a union at the ankle, *oo*, with the bones of the tarsus, which are seven in number, and constitute the heel or back part of the foot. These again are united to the *metatarsal* bones, *pp*, forming the body of the foot, and five in number. To these again are joined the *phalanges* of the foot, fourteen in all, two being attached to the great toe, and three to each of the others.

The *costae* or *ribs*, *rr*, proceed from the vertebrae or backbones, and are twelve in number on each side. They bend round in a circular manner from their point of union behind, and seven of them, called the *true ribs*, are joined directly by gristle or cartilage to the breast-bone, while the remaining five terminate anteriorly in a common cartilage, which unites with the sternum below. Altogether, the ribs form a large hollow space for the reception of the lungs, heart, and other organs, and protect them from injury. The ribs move in an easy joint formed with the back-bone, and, with the intercostal muscles, contract and expand to suit the motions of the lungs.

These are the principal bones forming the skeleton of the human being. All animals have not this osseous framework; it is only found in a certain number of classes, including man, quadrupeds, birds, reptiles, and some fishes, all of which, from the principal feature in their structure, are called vertebrated animals. Some of the other tribes of beings have their framework, corresponding in purpose to bones, on the outside of the body, in the form of a coat of mail. This is the case with the shellfish, as the lobster, and with many insects that have a hard external covering, as beetles.

THE MUSCLES.

The soft fleshy substance of the body, which gives plumpness and form to the whole, is the muscular part, or *muscles*. These are the instruments of motion. And when we consider the various positions which the body and its members assume, the agility and quickness with which the most intricate movements are made, the ceaseless play of the heart, the heaving of the lungs, and the singular rapidity of articulation and speech, we need not be surprised that these muscles, upon which all such movements depend, should be many in num-

ber, and deemed important agents in the animal economy. The muscles are of a reddish brown colour; they are composed of accumulated threads or fibres, arranged sometimes in layers, sometimes in a straight position, and sometimes obliquely. They are of an elastic nature, somewhat like a piece of India rubber, and, at the impulse of the will, are lengthened and shortened alternately. A muscle is generally thick or swelled out in the middle; it gradually gets thinner towards the extremities, and, in many instances, passes at one or both ends into a tendon, or tough white substance, which is attached to a bone, and serves the same purpose as a rope or cord, to fix the muscle to the point from which it is intended to act. These tendons are most numerous about the joints, especially the larger joints, where they allow of free and unrestrained action, and yet occupy little space in situations where a large swelling muscle would have been inconvenient. About the larger joints of the body, also, such as the knee, elbow, and shoulder-joints, there are numerous glands, which pour out an oily substance, that serves to lubricate the joints, and facilitates the play of the tendons. There are from four to five hundred muscles in the human body, all necessary for performing the various movements and operations of the complicated machine. On each side of the back-bone there are several layers of strong muscles, which are fixed by tendons to every projection of the numerous bones composing the spine. These muscles keep the trunk of the body erect, and also permit of the various motions of the back. There are a multitude of small muscles about the face, head, and eyes, whose various action imparts that expression to the human countenance which indicates the prevailing feelings and passions of the individual. The tongue is also supplied by intricate muscular fibres, giving to it that amazing volubility of action by which the vast number of sounds composing language are expressed. Many are attached to the lower jaw; but two in particular, the temporal muscles, proceed upwards through an arch formed by a projecting arm of the temple-bone, and are fixed to the tendons of the head. These two muscles are the most powerful in moving the jaws in the operation of chewing the food, and are very large in several animals of prey. Another flat muscle inside the cheek is called the trumpeter-muscle, because it assists in blowing from the mouth and in sounding wind instruments. The chest is supplied with numerous muscles, which move the ribs upwards and downwards in the action of breathing. A large flat muscle, called the diaphragm, stretched across the trunk from side to side, and separating the hollow of the chest from that of the belly, also contributes mainly to the process of breathing. The arm and hand are rolled inward and outward by a set of muscles, which are placed on the outer and inner sides of the respective bones; thus, the outside muscles act in a contrary manner to the inside, and reverse motions may be alternately performed. The muscles of the fore-arm are fixed to the scapula or shoulder-blade, to the chest, and to the clavicle, at the upper end, and to the bone of the arm at the other. The fingers are moved by muscles situated in the fore-part of the arm, and have long slender tendons, by which they are attached. Two beautiful provisions of nature are here observed: at the wrist, a circular ring of tendinous substance binds down the long tendons, which would, in their various motions, otherwise start up from their places. This ring at once keeps them in place and permits their free and unhampered play. The other provision is seen in the construction of the tendons of the fingers. There are two principal muscles which move the joints of the fingers, and two sets of tendons, which are inserted, the one into the middle bones of the finger, the other into the third row of bones, or the extremities of the finger. In order to preserve their free action, and to make them lie in the most convenient manner, there is a loop or slit in the shorter tendon, by which the other passes through to its insertion in the point of the finger. By

this means, the longest and strongest muscle moves the extremities of the finger, where the greatest power is wanted, without impeding the action of the other. The muscles which move the lower extremities are thicker and more powerful than those of the arms. Several large muscles, acting in opposition to each other, are situated around the thigh-joints, and move them. They are fixed, one end to the trunk of the body, some pretty far up, especially two, which are spread upon the front of the abdomen or belly, on each side of the spine, while the other ends are attached to the thigh-bone. Several thick muscles, also, are situated at the back of the trunk. Two large muscles compose the calf of the leg, and join to form the tendon of Achilles, which is fixed to the heel-bone; these muscles act powerfully in bending the ankle and in supporting the body in walking. The foot and toes are moved by several long slender muscles, situated in the leg, which have tendons attached to them, and terminating on the toes, exactly like those of the hand and fingers. The pelvis and lower limbs of man differ greatly from those of all other animals in their superior proportional strength, and in the number and fullness of the muscles. This was necessary, as man has been evidently intended by nature for the erect position. In the monkey tribe, whose general form approaches nearest to that of man, the narrowness of the pelvis or hip-bones, and the smallness of the muscles of the lower extremities, clearly show that they were not destined by nature for the erect attitude; in fact, all animals of this class are furnished with four *hands* or *paws*, the hinder pair exactly resembling those in front. When they attempt to walk on the hind extremities, they cannot put the sole to the ground, but press on it edgewise. By the nice balancing of the muscles, and the great force which they exert, man is enabled to stand erect, and to maintain a firm position, or move forward at pleasure, notwithstanding that the body diverges from the perpendicular line of the centre of gravity. The head is also balanced upon the neck by means of strong muscles, whose constant though unobserved exertion is necessary to maintain it in its position; for in young children, when the muscles are as yet weak, and in persons asleep, the head has an inclination to droop, and in the dead body it falls down on the shoulder and breast. The muscles of the neck, therefore, may be said to exercise a power in some degree involuntary, or not under the command of the will, as the majority of the muscles of the body are. But there are other muscles still more distinctly removed from under the guidance of the will. The heart is nothing else than a hollow muscle, which contracts and expands without the consciousness of the being; and, in like manner, the muscles which perform the act of respiration are not moved by the will. This division of the muscles into two classes, shows as perfectly as any thing could do, the care with which our frame is constructed. Had those muscles on which respiration and the action of the heart depend, been placed under the control of the being, their functions would have been liable to be impeded, at every turn, by circumstances. Now, these organs cannot cease to act for the most trifling period of time, without fatal consequences. The arrangement, therefore, which renders their operation involuntary, is one to be admired as essential to life and comfort.

THE BLOOD.—BLOOD-VESSELS.

The Blood.—The blood is the medium by which all the solid and fluid parts of the body are supplied with nourishment. In its composition, therefore, will be found the majority of the substances of which the body is composed. The blood consists of a solid coagulable matter, called *fibrin*; of a series of *red globules* which form the colouring matter; and of *serum*, or whey-like matter, which gives the whole the necessary fluidity. From the heart, the centre of the circulation, the blood is conveyed through the body by vessels called *arteries*, and is brought back to the same part by *veins*. The purpose of its thus making the circuit of the whole

body, is to supply the necessary materials for increasing the bulk and repairing the daily waste which takes place by perspiration and the perpetual operation of the numerous excretory organs. The blood is restored to its nutritious state by the chyle, a juice formed in the stomach and intestines from the digested food; this chyle reaches the heart by one of the large veins called the left subclavian; from the right side of the heart it goes along with the venous blood to the lungs, and there it is mixed with the oxygen, or vital portion of the atmospheric air, by which process it is converted into bright red arterial blood. In short, there are two distinct circulations of the blood in the system. By the one, the blood is conveyed and distributed over all parts of the frame, imparting, at every pulsation of the heart from which it issues, new life and nourishment to the whole. After traversing the body, it returns to the heart, deprived of its nutritious properties, and changed in colour from a bright to a dark red. Here the second circulation, which is through the lungs, commences. The blood is poured from the right side of the heart, which has divisions for the purpose, into large vessels which carry it to the lungs, and, spreading out into countless branches, penetrates and permeates their whole substance. Collected again by other vessels of equal number and extent, it is conducted by them to the left side of the heart, to be propelled anew through the frame, restored to its bright red hue, and repossessed of all its vivifying qualities. Both these changes are effected in the lungs. The chyle, which may be called the essence of our food in a liquid state, is conveyed from the stomach through the chest by a duct, which empties itself into one of the veins, immediately before the blood is transmitted through the lungs. It is in these organs that the chyle is thoroughly mixed up with the circulation; and it should be remembered, that this chyle is the only benefit, the only real food, extracted from all the substances received into the stomach, the remainder being entirely useless and excrementitious. From the chyle comes the material of the bones, of the fleshy or muscular parts, of the brain and nervous cords, of the hair, nails, enamel of the teeth, and, in short, of every different structure of the system. The average quantity of blood contained in an ordinary-sized person, is calculated at about 30 lbs. weight. The coloured globules of blood do not enter into the smallest vessels of the body, but only the thinner part of it, which has no colour; thus, in the eye, there are numerous blood-vessels, but these are so minute as not to admit the red parts of the blood; and this is a necessary provision of nature, in order that these organs may retain their pure transparency for the purpose of vision. In inflammation of the eyes, when these vessels are much enlarged, the red globules sometimes enter, and the eyes are then said to be blood-shot. What is called the pulse, is the flow of the blood through the arteries, which is caused partly by the impulse of the heart's contractions or beatings, and partly by the contractions of the coats of the arteries. The rate of pulsation in a person in the prime of life, is from 65 to 75 beats in a minute. In childhood the pulse is much quicker—from 100 to 140 beats; and in old age it again becomes slower than the medium standard. In fevers, inflammations, and other diseases of excitement, the action of the heart is increased sometimes to from 100 to 140 pulsations in a minute.

Blood-Vessels.—These consist of the heart, with its arteries and veins, that branch out through every part of the body, and carry the blood, by a constant circulation, through them. The heart is placed in the left side of the chest, a cavity divided into two parts by a thin membrane running perpendicularly down the centre, and supported below by the diaphragm. It is of a round or conical shape, with the base or broad part uppermost, and the point slanting downwards and towards the front surface of the chest. It is of a thick muscular substance, with hollow cavities inside, and numerous cords or pillars of fleshy or tendinous substance stretching through these to give them support. In

man and all the more perfect animals that breathe air through the lungs, it is double, or has two distinct sides, each performing separate offices. In fishes, again, the heart is single; in insects there is no proper heart, but a vessel that runs along the back, somewhat like an artery, through which the fluid corresponding to blood circulates through their bodies; other animals, still more simple in structure, have no trace of heart or blood-vessels. For these ends, the heart in man has two sides, a right and a left; and each of these sides contains two hollow cavities—the one called an auricle, from its fancied resemblance to a dog's ear; the other a ventricle, or belly. The manner in which the circulation of the blood is effected may thus be described in detail:—Two large veins, one from the upper part of the body, the other from the lower, enter the right auricle of the heart, and carry the blood, which has made the round of the body, into this cavity. Here it is of a dark purple colour, and it is called venous blood, from its coming from the veins. From the right auricle it is sent, by a sudden contraction or forcing together of the two sides of the cavity, into the right ventricle, immediately below the auricle, and communicating with this by a small opening furnished with a valve; by the right ventricle contracting, it is conveyed by the pulmonary arteries into the lungs, the two large cell-formed substances on each side of the chest, surrounding the heart. After passing through the lungs it is returned by the pulmonary veins to the left auricle of the heart; from this it is sent into the adjoining left ventricle; and, by a powerful contraction of this muscular cavity, it flows out by the great artery of the heart, the carotid, which distributes it through every part of the body, again to be returned by the veins: and thus the round of circulation is continually going on.

The heart being an extremely thick muscle, the force with which it contracts is very considerable. The left ventricle of the heart, too, although somewhat smaller, is much thicker and more muscular than the right, it having to send the blood through the whole of the body. A beautiful provision is observable in the heart, to prevent the flowing back of the blood into its different cavities during their alternate pulsations. In the passage of communication between the left auricle and ventricle are placed valves, which, when the ventricle contracts to send the blood through the aorta, close accurately, so as to prevent a reflowing into the auricle. There is the same provision between the right auricle and ventricle, and also at the mouth or commencement of the aorta and pulmonary arteries, and the veins which communicate with the right auricle. Some of these valves are of beautiful structure; they are composed of three flaps that join accurately over each other; and to prevent their being pushed by the impetus of the blood beyond their proper position, they have little tendinous cords attached, of exactly the length required. In the child before birth, as it cannot breathe, and therefore the lungs are not used, there is a small hole or communication between the right and left auricles, by which the blood from the veins flows directly through to the arteries, and thus avoids going to the lungs; this hole closes up whenever the child begins to respire. The aorta, or great artery of the body, after it leaves the heart, passes upwards in the form of an arch, when it gives off the carotid branches to supply the brain, and face, and arteries to the arms and chest. It then bends downwards, and gives off branches to the stomach and other viscera; and when it comes to the lower part of the belly, it divides into two main parts, which become the arteries of the pelvis, thighs, and legs. The arteries of the body are composed of three coats or coverings, the principal one being a thick muscular ring, which encircles the artery, and which contracts and expands so as to assist in sending the blood onwards. The principal trunks of the arteries lie deep in the fleshy parts of the body; but their ramifications are so numerous and minute, that they pervade every particle of the human structure—bones, gristle, and

every other texture. These extreme branches of the arteries being so minute, anatomists have had great difficulty in tracing the exact point at which they pass into veins. That they do so, however, is undeniable, and is partly seen on the surface of the brain. The veins are another system of vessels, which return the blood from the extremities of the body to the heart. They are larger and more flaccid than the arteries, and are distinguished from them by having no pulsation. A large vein generally accompanies the corresponding artery, but the great proportion of the veins lie more towards the surface, and are easily distinguished, swelling out under the skin. The numerous veins from the lower extremities join into one trunk in the belly, which vein, after passing through the liver, as will be afterwards described, joins the right auricle of the heart, the blood from the upper half of the body joining also by another similar vein. In the veins of the extremities that hang downwards, and are apt to be gorged with blood, there are inserted numerous valves, at short distances, which prevent reflux of any kind.

THE BRAIN—NERVES AND NERVOUS INFLUENCE.

The brain, as already mentioned, is contained in the cranium. It is a soft mass of matter, enclosed in certain protecting membranes beneath the bones of the skull. As the organ by which mind acts, and chief seat of the nervous energy, the brain may be described as the most important and dignified of man's bodily parts, and well deserves the most careful investigation. The brain is divided by strong membranes into two main sections—the cerebrum or proper brain, which lies in front beneath the brow and on the top and sides of the head, and the cerebellum or lesser brain, which lies behind. Both are longitudinally divided into halves or hemispheres, and also into lesser parts called lobes. The annexed figure offers a lateral representation of the different parts of the brain, as it lies beneath the skull, with its beautiful and minute radiation of nerves proceeding to the eye and other external instruments of the organs of sense.

The cerebrum or principal part of the brain is indicated by the letters, *a a a*. The cerebellum, distinguished by the letter *b*, terminates below in the *medulla oblongata*, *c*, the cylindrical pulpy cord by which a union is formed between the brain and *spinal marrow*, *d*. The latter part is the long cord of soft matter formerly mentioned as lying in the canal formed by the range of the spinal bones. It is round, of the thickness of the finger, of the same kind of substance as the brain, and formed of smaller nervous cords, running parallel to each other: it runs along the whole length of the back down to the pelvis. The

nerves are small whitish-looking cords, which proceed from the brain and spinal marrow, and spread out in innumerable branches to every part of the body. A large branch of a nerve generally accompanies every large artery, and every important part of the body has a branch of a nerve sent off to it. The nerves for supplying the organs of smell (1), of seeing (2), of hearing (3), together with the great sympathetic nerves, which give branches to the heart, lungs, stomach, and other important viscera, proceed directly from the brain. The nerves of motion and sensation sent to the various parts of the trunk and extremities, take their origin, with a few exceptions, from the spinal cord. Two sets of nervous branches proceed from the cord on each side, corresponding nearly to the junction of every vertebral bone; and it is found that a branch of these nerves imparts motion, and the other sensation or feeling. The brain has a covering of three thin membranes; the outward one strong and thick, the inner extremely thin and delicate. The nerves, which are soft and pulpy inside, have also a thin external covering which protects them. The nervous branches are never seen or felt in the living body, and what are vulgarly called nerves, are the tendons of the muscles, the erroneous title being given chiefly to those about the wrists, fingers, and ankle-joints. Their great numbers and minute divisions are manifest, however, because we cannot prick any part of the body with the sharp point of a needle, without wounding some of them, and thereby causing the sensation of pain. When the nerves are injured in their powers by disease, the sense of feeling in the part is entirely lost. The brain in the lower animals is not generally nearly so large, in proportion to their bulk, as in man; and the cerebrum, or upper brain, is often smaller in them than the cerebellum, or lower brain. In many classes of the inferior animals there is no distinct brain, but only nerves running along their bodies, and joining into knots or ganglions. The nervous system of insects and worms is of this description. In the polypus, and some other similar animals, a distinct nervous system can scarcely be traced.

It may be proper here to make some observations on the functions of the brain, considered abstractly from its anatomy. Man surpasses all other animals in the height and proportions of the forehead, and in the comparative mass of brain in the upper part of the skull. In the human head the lower parts of the face bear a smaller proportion to the forehead than in the brutes. The face is placed in nearly a perpendicular line with the forehead, instead of projecting outwards into a snout, as in the lower animals. The brute face is merely suited for the purpose of animal wants and for defence; the jaws are long and narrow, supplied with thick, strong muscles, and short teeth; there is not the elevated nose, which in man forms a distinguishing feature—the arched eyebrows—the exquisitely formed lips, and the rounded chin; above all, there is not that play of varied expression, that air of intelligence, and that indescribable emanation of a rational mind, that ray of divinity, at the appearance of which the most wild and ferocious of the brute creation are awed and subdued. But, besides, the Creator seems to have allotted characteristic external signs to express the passions of the mind, that in social life man might not easily impose on his fellow-man; for the various muscles of the face express the several passions of the mind so faithfully, that they may be even represented in painting. This is said to be the natural expression, and would appear to be understood even by animals; for a dog, on looking to the countenance of his master, easily recognises the mute expressions either of commendation or dissatisfaction. From the action of these muscles being so often repeated,

The Brain.

physiognomy arises; the action of the prevailing muscles fixes an enduring expression on the features; and thus traces of frequent anger often remain in the countenance after the passion itself is gone off. With the power of speech and reason, man has also the means of expressing his feelings and passions by laughter and weeping, manifestations which are not found in the lower animals. Weeping proceeds from a deep emotion of the mind, and seems an effort of nature to relieve the system of grief. It usually begins with deep inspirations of the lungs, after which follow short alternate inspirations and expirations, and it is finished with a deep long-drawn expiration, which is immediately followed by an inspiration. When moderate, it certainly relieves the distress arising from grief. Laughter has its rise from some ludicrous ideas impressed upon the mind, and would seem to arise directly from a sort of titillation conveyed to the branches of certain internal nerves, probably those of the diaphragm; immediately to this succeeds a number of imperfect inspirations and expirations, which seem to be checked by the contraction of the glottis in the throat or larynx. Laughter in a moderate degree may be conducive to health, as it gives impulse to, and ultimately promotes, the circulation; carried to excess, however, it may prove dangerous, from accumulating too much blood in the lungs. Sneezing consists of one deep inspiration, succeeded by a powerful single expiration, and seems to consist of a convulsive effort of the muscles of breathing to throw off some cause of irritation in the sensitive membrane of the nostrils. The common hiccup is a spasmodic action of the muscles of the stomach, caused by something irritating the stomach itself. Some of the causes by which our mental happiness is either increased or diminished, proceed entirely from the bodily sensations. Any gentle stimulus applied to a nerve seems to cause a feeling of pleasure; strong stimuli, or any causes disturbing seriously the natural condition, produce pain. Itching is akin to pleasure, and in both cases the flow of blood is increased into the part in which either pleasure or titillation is perceived; but when farther increased, it degenerates into pain, or excessive sensations in the nerves. Anger violently excites the motion of the spirits, increases the motion of the heart, the frequency of the pulse, and the strength of the muscles; forces the blood into the extreme vessels; and even sometimes bursts the smaller vessels themselves: passion also increases the secretion of bile. Grief weakens the strength of the nerves and action of the heart, retards the pulse, destroys the appetite, and frequently produces paleness, looseness of the bowels, indigestion, and those slow or lingering diseases that take their rise from an interruption of the secreting glands, and a disease of their structure. Fear diminishes the force of the heart, weakens the muscular motions, relaxes the whole system, and, if long continued, causes a general sinking of the body. Excessive terror often increases for the moment the muscular strength, even to convulsions; excites the pulse, interrupts the course of the blood, and in not a few instances has produced sudden death. Love, hope, and joy, promote all the salutary actions of the body, gently quicken the pulse, promote circulation, increase the appetite, and aid the cure of diseases. Excessive and sudden transports of joy, however, often prove fatal, by increasing the motion of the blood, and exciting a fit of apoplexy. Shame, in a peculiar manner, retains the blood in the face, as if the veins were obstructed; when felt in an extreme degree, it has also been known to prove the cause of sudden death.

THE LUNGS OR BREATHING APPARATUS.

In the highest part of the cavity of the chest, on each side of the breast-bone, the lungs are situated. A membrane passing from the breast-bone to the back, divides them into two portions, the right lung and the left lung. The right lung consists of three sections called *lobes*, the upper, middle, and lower; the left lung, rendered smaller in bulk by the presence of the heart in the same cavity, has only an upper and a lower lobe.

The lungs have a dark bluish appearance, a familiar example of which is afforded in the *lights* of sheep, that part generally appended to the heart and wind-pipe. Inside they are composed of an immense number of cells, which alternately inflate or collapse as the lungs are filled and emptied of air. When an inspiration is made, and the lungs are filled with air, these cells become expanded; and the blood sent from the right side of the heart, and spread over the cells, is exposed through an extremely thin membrane to the air. An important change, as formerly alluded to, here takes place on the blood: from being of a dark purple colour, it immediately changes to a bright scarlet, having absorbed or taken up all the oxygen, or vital part of the air, and parted with a corresponding volume of carbonic acid gas or fixed air, which it had acquired in its circuit through the vessels of the body. So essential is the matter imparted by the air to the blood for sustaining animal existence, that the breathing cannot be suspended even for a very short period without extinguishing life. It is probable, too, that the heat of the body is generated, and constantly kept up, in some way or other, by means of this process of breathing, and the change which the blood undergoes. We know, at least, that the evolution of carbonic acid cannot go on, in ordinary chemical processes, without an accompanying discharge of heat; and hence it is presumed that the vital warmth, derived by the body from the blood, may be in this way produced. The lungs, like every other internal organ, are covered with a thin transparent membrane called the *pleura*: this membrane, as well as the substance of the lungs themselves, is liable to inflammation; and hence the name of the disease called *pleurisy*. The trachea or windpipe, the communication between the mouth and lungs, is a hollow tube, having a series of cartilaginous rings passing round it, to prevent the possibility of its being compressed either by external means, or from the food in the act of swallowing, and, in consequence, the breathing obstructed. It takes its rise from the bottom of the mouth, and passes down in front of the neck, where its strong cartilage may be seen and felt. At its lower part it divides into two parts, like the prongs of a fork, one going to join the right section of the lungs, the other the left. Lungs for breathing air are only found in the higher classes of animals. Fishes are furnished with gills, those comb-like substances which lie within a flap on each side of the head; over them a stream of water is constantly sent by inhaling it at the mouth in a similar manner to breathing. The air, which is always present in considerable quantities in water, is thus absorbed by the blood-vessels while ramifying over the gills, and all the purposes of breathing are answered. In insects there are no lungs, nor do they breathe by the mouth, but along the sides of their bodies, by means of numerous holes with small tubes or spiracles, leading to a longer middle tube, by which the air enters and mixes with their fluids. When we descend lower in the animal scale, even this substitute for breathing ceases, and probably the vital air is absorbed by such animals by simple pores or openings in the skin.

THE TEETH.—DIGESTING APPARATUS.

The first process performed in connexion with the supply of nourishment to the body is that of masticating the food, and this is the office of the teeth.

The Teeth.—These are placed in the upper and lower jaw, to which they are attached by roots, which sink into the porous sockets of the jaw, somewhat in the same manner as a nail is fixed in a piece of wood, though they are retained in place chiefly by the softer parts around. The teeth are composed of bony matter, covered externally with a thin coat of an extremely hard substance, called enamel. The teeth are furnished with nerves and blood-vessels, and have thus vitality like the rest of the body, although possessing it in a less perfect degree than most other parts of the structure. Hence they are very liable to disease and decay. In decaying teeth a blackish spot is first perceived upon

the outer crust or enamel; this substance gradually gives way, and then the bone below proceeds to rapid decay. The irritation of the air, and particles of the food, inflame the nerves and soft pulpy parts inside, and thus the excruciating pain of toothache is produced. The first set, or temporary teeth, begin to make their appearance in the child about the fifth or sixth month, and towards the end of the eighteenth month the whole set of temporary teeth, consisting of twenty, have generally cut through the gums. These teeth continue till about the sixth or seventh year, from which time, till about the twelfth or thirteenth year, they gradually fall out one by one, and are succeeded by the second or permanent teeth. The roots of the temporary teeth are much smaller, and sink less deep into the jaw than their successors. The rudiments of the second set of teeth begin to form early in cavities below the others, and, gradually growing and pressing upwards, displace them. The number of the permanent teeth is thirty-two, consisting of sixteen in each jaw. The four front teeth are called the incisors, and have one long root; on each side next to these is one eye or dog tooth; then there are placed two small grinders on each side, having double roots, and three large grinders, or molar teeth. The last of these is called the wisdom tooth, from its making its appearance latest in the jaw, from the seventeenth to the twentieth year, or even later. By this change and gradual succession of teeth, we have a beautiful provision of nature for permitting the jaws to increase in size, and, at the same time, for preserving the relative positions and regularity of the different teeth; for had the first teeth of childhood been permanent, it is impossible that the jaw could have increased in growth without deranging the order and position of the whole. The teeth of various animals differ according to the kind of food on which they live. In carnivorous, or flesh-feeding animals, the teeth are sharp-pointed, and adapted for tearing their prey to pieces; in those animals called graminivorous, that live on grasses and other herbage, the teeth are of a rounded form, with broad surfaces, and the grinders are furnished with several layers of the hard enamel, following each other in succession, with a slight layer of common bone interposed; so that, when the grinder is worn down by the friction of chewing, it is not rendered useless, but a new layer of the enamel is presented at the worn-down surface. Some animals, as the hare, rabbit, beaver, and mouse, have the front teeth of a chisel shape, with enamel only on the outer side of them. These animals are called gnawers, because they chew or gnaw down their food in this particular manner; and by the inner soft part of the tooth being liable to be worn down, while the outer is harder, the enamel is thus always kept with a sharp edge. Some animals have large projecting tusks for defence, as the elephant, wild-boar, &c.; others, as fishes, are provided with teeth more for holding fast their prey than for mastication. Many have no proper teeth at all, as birds, worms, and other soft formed animals. Man is characterised by having all his teeth set close to each other in a half circle; they are of a medium form, between that of carnivorous and herbivorous animals; the front teeth are adapted for cutting; the canine are sharp, though not of undue length; and the grinders are suited for masticating vegetable and farinaceous matters, as nuts, &c. In short, the form of the teeth of man evidently points out that he is adapted to live on a mixed kind of diet, or a conjunction of vegetables and flesh.

Stomach.—Behind the windpipe, taking its rise also from the bottom of the mouth, lies the oesophagus, or tube which passes into the stomach. This tube expands at the top into what is called the pharynx, forming the whole of the upper part of the throat immediately behind the tongue. Into this cavity the windpipe opens, and, to guard against any particle of the food or drink passing into the windpipe instead of into the passage to the stomach, there is a little tongue or valve which closes accurately over the mouth of the windpipe every time food or drink is swallowed. When the substances

have passed, the valve again springs open, and admits of free breathing. To show how accurately and precisely every part of the human machine performs its duties, a celebrated writer has instanced this same valve, which, in a multitude of persons dining together, not one time out of a hundred in any one individual instance is at fault. When a drop of fluid or particle of food does by chance insinuate itself into the windpipe, so sensitive is this tube, that a convulsive cough is excited till it is again expelled. There is another little tongue or flap attached to the roof of the palate, and seen above the tongue when the mouth is opened. This, which guards the passage to the nose, is not, however, to be confounded with the other, which is farther down the throat, and invisible. The oesophagus, or gullet, passes down through the chest, traverses a ring in the diaphragm, that large muscle which stretches across the lower ribs, and which assists so materially in breathing. Immediately below this muscle, on the left side, is situated the stomach, which is partly sustained in its place by being attached to the oesophagus, or tube from the mouth. The stomach is an oval bag of considerable size, occupying a slanting position immediately below the heart, with its right side overlapped by the left edge of the liver, and extending to the lower end of the breast-bone. The stomach has three coats—an external membranous one, a muscular, and a soft villous inner covering. The upper passage, by which this bag communicates with the oesophagus, is called the *cardiac* opening; the lower, where the first gut commences, is called the *pyloric* orifice.

Digestion.—One of the most important operations in the animal economy, is that of digestion, whereby the various substances used for food are dissolved in the stomach, and undergo changes, by which they are formed into matter fit for entering into the composition of the different parts of the body, to nourish its growth, and supply the daily waste which takes place in the system; for such is the constitution of animal bodies, that the substances of which they are composed are liable to constant waste; the solid parts are worn down, and a large quantity of fluid is constantly given off by the exhalant vessels, both from the skin and the surface of the lungs. This is manifest in the sweat and the vapoury exhalations constantly passing off by the mouth; and there is also an imperceptible perspiration regularly proceeding from the surface of the body, which has been computed to amount to several pounds in the course of a day. It must be evident, therefore, that if this waste was allowed to proceed but for a very short period, the body would soon be reduced to a state of complete decay. A constant supply of new material is therefore daily needed, to replace that which is wasted; and thus it has been supposed that a human body changes its whole materials many hundred times from the period of its birth till death; and that an individual, as regards his mere corporeal structure, is not at all the same at the period of manhood to what he was when a boy, nor in old age what he was in his prime. Although this change then is complete, even to the bones and most solid parts of the frame, it is brought about so gradually, and with the regular and minute substitution of one particle for another, that it is never perceptible. Man has been called, with relation to his diet, omnivorous, from his being adapted to live on every kind of food, whereas most other animals are confined to one particular description. The carnivorous animals live on flesh alone, the graminivorous on grass and green herbs, and the granivorous on grains and other smaller seeds. These animals never change their respective diets; nor, from the construction of their teeth, stomachs, and intestines, were they ever intended to do so. But in man it is plainly evident, from his anatomical structure, that he was intended to feed on every sort of food promiscuously, or that he could adapt himself to either animal or vegetable fare, as habit or necessity impelled him. Man also differs from brutes in resorting to the arts of cooking, whereby the food is put into a state more fitted for digestion, and for yielding a sufficiency of nutritious aliment. The

food being received into the mouth, is broken down and masticated by the teeth. It is here also reduced into a soft pulp by the saliva, which flows into the mouth by the salivary glands; and thus being sufficiently broken down and softened, it passes into the stomach. The stomach has numerous glands situated on its inner coat or surface, which secrete a peculiar fluid called the gastric juice, which is clear and colourless, with little taste, or smell, or sensible qualities. On this fluid depends the important office of digestion. It has the power of coagulating substances in the stomach, of preventing the contents of the stomach from passing into a state of fermentation or putrefaction, and of dissolving the whole into one homogeneous mass. When the stomach is first filled with food, it appears to remain there for a short period without undergoing any change; gradually, however, successive portions of the food, as they come into contact with the gastric fluid, are dissolved; till at length, in a shorter or longer period, the whole is collected into a thin greyish paste, called chyme. In the upper or left division of the stomach, it would appear, from some recent observations, that the food is freed from its superabundant moisture, which drains off by some undiscovered means to the blood-vessels, and from thence to the kidneys. The chyme then, as it is gradually formed, moves to the other extremity of the stomach, called the pyloric, where it passes out to enter the intestinal canal. It would appear, also, that the pylorus, or lower mouth of the stomach, has a sensitive power, whereby it freely permits the digested chyme to pass out, but refuses exit to the undigested matter. The chyme having passed into the first part of the intestines, or duodenum, is then mixed with the bile from the gall-bladder, and with the pancreatic juice. Both these substances, especially the bile, seem essential for the conversion of the chyme into proper alimentary matter, but their peculiar action has not yet been satisfactorily explained. That the liver and bile ducts are of the utmost importance, however, cannot be doubted, from their magnitude, and the care with which they are supplied with numerous vessels, and from their being universally present in a great proportion of animals. The chyme having passed through the duodenum, and having been mixed with the bile and pancreatic juice, now changes its appearance and properties, and becomes the chyle, or nutritious matter destined to supply the various parts of the system with nourishment. The digested mass is passed gradually along the course of the small intestines, urged forward by what is called their *peristaltic* motion, which is effected by a successive contraction of their fibrous coats. Here the minute mouths of the lacteal vessels, opening on the inner surface of the small intestines, take up the chyle, and carry it, as has already been described, to the receptacle of the chyle, and then by a duct running up the chest along the spine, called the thoracic duct, it joins the blood-vessels. The refuse of the aliment which has not been taken up by these lacteal vessels passes on through the large intestines, and at length is ejected from the body. Digestion is not brought about, as has by some been supposed, by any mechanical means, as by the grinding powers of the coats or sides of the stomach, nor by heat alone, nor fermentation, nor by the simple resolution of the food into a fluid; but it is evident that it undergoes a series of chemical actions in the stomach and bowels, whereby its nature and properties are completely changed; and thus animal and vegetable substances, however different, are reduced to one peculiar kind of fluid, the chyle, which, though it may be found to vary slightly according to the kind of food, is, in its general properties, always the same. The gastric juice varies in different animals. In those which feed on vegetable matter, it dissolves these substances only; whereas grain and vegetables pass through the stomach of a purely carnivorous animal without undergoing any change. The gastric juice has this singular property, too, that although it readily dissolves dead animal matters, and reduces them in a

short time to a thin pulp, it will not usually act on the living fibre; so that, after death, the coats of the stomach have been found dissolved into holes, by the same juice, which, in the living body, had no such effect. This forms a most important fact in medical jurisprudence. A stomach of some kind or other is found in all animals; for it is by this organ that nutrition and growth are solely promoted. There are some very simply formed animals whose whole body consists of an oval hollow bag, or stomach, with a simple outlet for the mouth to take in nourishment, and no other organ whatever. The common polypi have simply a mouth and hollow stomach; with several tentacula, or arms, by which the creature seizes the worms and grubs on which it feeds; these it swallows, abstracts their juices, and then voids the remainder from its mouth. The common leech has its whole body divided into a number of small cells, like a piece of honey-comb; and these receive the water, and sometimes blood, on which it feeds. Flesh-feeding animals have a simple bag for a stomach, and their food is easily and soon digested. Those animals, again, that feed on grass, which is of more difficult digestion, have three and four stomachs, into which the food successively passes after it has been masticated or chewed a second time in the mouth. This is the case with cows, sheep, deer, &c. Birds that feed on grain have first a sap-bag, or crop, into which the food enters, and remains for a considerable time, mixed with a juice somewhat like saliva; here it is softened and rendered moist, preparatory to its passing into the true stomach, or gizzard, which is an extremely strong muscular bag; in this, with the assistance of a number of sharp-pointed pebbles, which such birds always swallow, it is ground down and acted on by the gastric juice. This compensates for the deficiency of teeth in fowls. Crabs and lobsters have no teeth in their mouths; but in their stomachs will be found three or more teeth, which assist in grinding down the tough sea-weed on which they feed. By domestication, the qualities of the gastric fluid may be so changed, that animals accustomed to live entirely on flesh will exist and thrive on a vegetable diet. This is the case with dogs, and many birds. All these peculiarities in the natural history of animals illustrate, at least directly, the uses of the digestive organs in the human being.

THE LIVER, &c.

The Liver.—Opposite the stomach, on the right side, lies the liver, a large flat substance, of a dark brown colour, divided into two lobes. The liver has a round, convex upper surface, and is hollow or concave below; it is also thick and solid at the back part, and its edge becomes thinner towards the front, where it lies over a portion of the stomach and bowels. It is suspended in its place by several ligaments attached to the surrounding parts. In the under side of the liver, in a small hollow, is situated the gall-bladder, a small oval bag which contains the bile. A tube from this bladder, called the bile-duct, passes into the upper portion of the bowels, carrying the bile there. The liver is supplied by several branches of an artery in the usual way that the other organs are, but it has also a peculiarity which no other organ of the trunk possesses. The large veins, which return the blood from the lower part of the bowels, before going to the heart, enter the substance of the liver, and there spread into innumerable branches throughout its whole surface. From this venous blood the bile is supposed to be secreted, and after having yielded this substance, the vessels collect again into one large trunk, and join the large vein which carries the blood to the heart. The liver weighs, on an average, from three to four pounds weight, and the quantity of bile which it secretes, taking into account its large supply of blood, must be very considerable. The greater proportion of animal beings are provided with an apparatus of some kind or other for preparing a supply of bile, and in many the liver bears a large proportion to the

other contents of the belly. In some animals, as the horse, the gall-bladder is wanting, there being merely a duct to convey the bile into the intestines. In the lowest classes of animals, all traces of liver or gall-ducts disappear.

The Spleen.—This substance is situated below the stomach, on the left side, betwixt it and the ribs. It is in shape a flat oval, and of a dark iron colour. No duct or opening has been discovered proceeding from it, nor has its use been as yet accurately ascertained. It possibly serves to relieve the stomach of its surplus quantity of blood while this organ is distended with food; and the splenic vessels have also been held by some to contribute to the secretion of the gastric juice. The spleen, it is remarkable, has been frequently cut out from living dogs, without causing any apparent derangement in the health or digestion of these animals.

The Pancreas.—This substance, known under the name of the sweet-bread, is a large oblong gland (or secreting organ), lying across the back part of the belly, extending between the spleen and the middle of the liver. This gland pours out a substance something like the saliva or spittle of the mouth; and by means of a small duct or canal, empties it into the upper bowels, along with the bile from the gall-bladder, both these substances aiding in digestion, and the preparation of the nutritious fluid to be afterwards mentioned.

Lacteal Vessels.—These are innumerable small tubes, proceeding from the ileum or small intestines, along their whole course, and spreading along the mesentery, where they form an immense number of small knots, or glands, by joining together. These are the vessels which take up the fluid chyle, or milky-like substance, after it has been digested and properly prepared in the stomach and bowels. From these mesenteric glands, the chyle is conveyed by these ducts or canals to another large gland, situated in the loins, on the right side of the aorta, and immediately below the diaphragm, called the receptacle of the chyle. From this receptacle the thoracic duct arises, and passing upwards by the side of the aorta, or great artery of the body, it joins the left subclavian vein, lying under the left clavicle or collar-bone, and thus pours the whole of the chyle into the general circulation.

The Kidneys.—These are situated in the loins, one on each side of the back-bone, about one-third up the spine. They are in shape somewhat like a French bean, and their internal structure consists of a number of minute porous tubes. They each at the middle hollow part receive a large artery, and their use is to filter from the blood the superabundant fluid, and salts and juices unnecessary for the system, and transmit these, by means of two small tubes, called the ureters, to the urinary bladder. These tubes enter the back part of the bladder in a slanting direction, which serves the purpose of valves, preventing a flowing back of the fluid when the bladder is full. The bladder is situated in front, immediately above the bone of the pelvis, called the pubis.

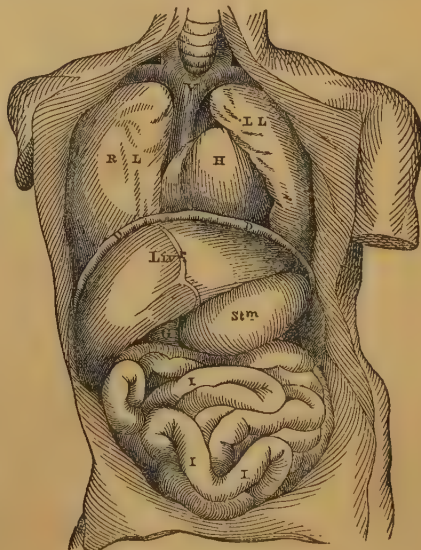

The whole cavity of the belly is lined by a thin membrane, called the peritoneum, which is double, being reflected from the sides of the cavity over the whole of the intestinal organs. This peritoneum is liable to inflammation, in the same manner as was mentioned of the pleura, which produces a very violent disease. The coats of the intestines, too, are also subject to the same affection. Dropsy may arise from water being formed between the two folds of the peritoneum.

The Lymphatic Vessels.—These are another distinct set of vessels spread over all the inner cavities of the body, and also throughout the skin, on which they open by innumerable small mouths. Their office appears to be to take up from the blood a thin lymph, which they convey into the receptacle of the chyle and thoracic duct, and also to exhale or carry off from the skin the superfluous moisture of the body. This moisture forms the sweat, and several pounds of fluid are daily drained off from the body in this manner, even when little or no bodily exercise is taken, for perspiration continually goes on insensibly. These vessels are composed of a

series of extremely small tubes, and, joining and interweaving, form numerous glands, especially in the groin, armpits, and neck; when swelled by disease, they harden and enlarge, forming knots like a pea or bean. But they are no less numerous on the surface of the inner cavities of the body as on the skin; they are found in the brain, on the surface of the lungs, where they give out a large proportion of vapour at every expiration of the breath, and in the abdomen or belly. It is a disease or sluggishness of these vessels, whereby they do not perform their necessary duty of taking up all the superabundant fluids, that causes accumulations of water in the chest, belly, and legs. The branches of the lymphatics of the lower half of the body join the receptacle of the chyle; those of the upper part enter the thoracic duct just before the latter pours its contents into the subclavian vein.

THE BOWELS.

From the lower or pyloric orifice of the stomach, the duodenum, the first portion of the intestinal canal, takes its origin. This gut passes below the liver and receives the bile-duct, and the duct from the pancreas, when it terminates in the jejunum, which again passes into the ileum, or principal portion of the small intestines. These are of great length, and occupy a great part of the abdomen, being folded and twisted backwards and forwards in many intricate windings. At the end of the ileum, the colon, a large gut, makes an arch upward towards the right side, and across the belly, and descending at the back part, ends in the short bag, called the cæcum, which joins the rectum, the termination of the intestinal canal. The whole length of the intestines in man is generally about six times that of his average height, or from thirty to thirty-six feet. In all animals that feed on vegetables, the intestines are of great length; whereas, in those that derive their nourishment from animal food, they are of much shorter proportions. Two membranous substances, called the omentum and mesentery, run along nearly the whole length of the intestines, and serve as a means of their attachment and proper suspension in their places. The bowels have three coats—an external one, common to them with the other viscera, a muscular coat, and an internal mucous covering.

Organs of the Chest and Abdomen.

R.L., the right lobe of the lungs; L.L., the left lobe; H, the heart; V, the great arteries; D.D., the diaphragm, a muscle separating the chest from the lower regions; Liv., the liver; Stm., the stomach; G, the duodenum, or beginning of the small intestines; I.I., the intestines or bowels.

It is of the greatest importance to health that the bowels, through which all rejected matter from the stomach is to pass, should be kept in an easy open condition, and that there should be a free passage through them once every day. When nature fails in this respect, a small quantity of medicine, under proper advice, may be taken; and the irritation which it causes usually leads to the desired result.

THE SENSES.

Man possesses five senses—sight, hearing, smell, taste, and touch, each of which acts through the medium of appropriate instruments, and all regulated by and acting in connexion with the brain.*

Sight—the Eye.—The eye is the exterior instrument of sight, and is a most beautiful and ingeniously constructed object. The eye may be compared in its structure to a telescope, the purpose of both being to collect the rays of light proceeding from the surface of bodies, to concentrate these rays, by means of a refracting lens, into a focus, and, therefore, to form a very small image or picture of the object before them. The human eye is placed in a large hollow or socket in the upper bones of the face, surrounded by fatty substance, and the various muscles necessary for moving the eyeball and eyelid. At the upper and outer angle of the eye-socket is placed a gland, which secretes the tears that serve to moisten the delicate surface of the eye, to wash off any dust or other substance, and to keep the eye continually wet and transparent, for the purpose of perfect vision. The tears, after spreading over the eyeball, collect at the inner angle, where, at each corner of the eyelid, both above and below, there is a small opening visible, which carries the tears down a passage into the nose. The edges of the eyelids are also supplied with glands, which pour out a mucus that prevents them from adhering together; and these, when irritated and inflamed, are often the seat of disease. The membrane which covers and imparts the white colour to part of the eyeball in front, is called the sclerotic coat. The middle transparent part of the eye in front is called the cornea, which is filled with the aqueous humour of the eye. Immediately behind the cornea is seen a circular fringed-like substance, which varies in colour in different individuals, being blue, black, hazel, &c.; and hence it is called the iris, or rainbow curtain. This iris has the property of opening and closing, according to the quantity of light which falls upon the eye; and thus the pupil, a black circle contained within the iris, is enlarged or lessened. Behind the iris is situated the crystalline lens, in shape resembling the small lens or ground glass of a common telescope, but of unequal swell on each side, being more flattened before than behind. This lens is contained within a capsule, or thin covering of delicate membrane. A familiar example of the lens of a fish's eye is presented every day in that white globular substance found in such eyes after boiling. The heat coagulates the lens, which is of the same nature as the white of an egg; and in the fish it is nearly a circular body, to adapt the animal's vision to the dense medium of water. The lens is the substance which receives the rays of light entering the eye, and refracts or bends them inwards, whereby they are collected into one point upon the back chamber of the eye, or retina, and thus a minute picture of the object seen is formed. If a bullock's eye is taken when fresh, and a hole cut in the skin covering the back part, and then presented to the light with a piece of white paper put opposite the hole, a representation of the objects in front of the eye

will be distinctly traced on the paper. When through disease the lens becomes of an opaque white colour, and will not transmit the rays of light, the affection is known as the cataract, producing blindness. The fluid filling the lens is called the crystalline humour. Behind the lens is the back chamber of the eye, filled with a fluid, called, from its thickness, the *crystalline* humour. Over this back chamber the retina is spread out like a lining or covering. It is covered over with a black pigment, the better to prevent the intermixture or reflection of the rays of light. On this membrane the optic nerve, which comes front the front part of the middle brain, and enters the eyeball at the back part, spreads out in numerous branches; and here the small images of the outward objects presented to the eye are painted in miniature. All these objects are painted on the retina in a reversed position, or turned upside down, the same as happens in a common microscope; and how they are perceived in their upright position through the medium of sensation, is a curious question, not easily admitting of explanation. Each eye, too, forms a distinct impression of every object, and yet things are not seen double, but both eyes combine to give one impression to the brain or seat of perception. Besides the numerous muscles which roll the eyeball in various directions, to adapt it to the various positions of vision, there seems also a power, in the cornea or front portion of the eye, whereby it can flatten or become more convex according as the object viewed is at a greater or less distance from the eye, thus adapting itself to the focus of vision in a similar manner as the joints of a telescope are drawn out or pushed inwards. When the cornea is, from its natural form, of too rounded or convex a structure, distant objects are always seen imperfectly, hence causing what is called night-sightedness; on the other hand, when it is too flat in form, near objects are then seen indistinctly. This change occurs generally to the cornea as old age approaches, and hence spectacles, or artificial rounded lenses, to aid the flatness of the eye, are in such cases made use of with the desired effect. From the different densities of the three humours composing the eye, the refraction, or breaking of the light into the various coloured rays, is avoided. This for a long time was a great objection to telescopes, till different kinds of glass were joined together in the lenses, thus imitating the resources of nature in the eye. The eyes are supplied by two large optic nerves, proceeding by separate trunks from the brain; they join together for a short space within the cranium, where they again separate, and each entering an opening at the back part of the orbit, spreads out into branches over the retina. Sometimes these nerves lose their power of sensibility, and total blindness is occasioned without any perceptible disease of the eye: this is called *amaurosis*, and is in most cases incurable. All the larger and more perfect animals are possessed of eyes. Birds have in general very acute vision, especially birds of prey, to enable them to distinguish their victims at a great height in the air. They have also a third eyelid, or transparent membrane which covers the eyeball when they are darting suddenly through the air, and which thus protects the delicate organ of the eye from injury, at the same time that it allows the transmission of a sufficient quantity of light. Fishes have eyes of a somewhat different form from land animals, to adapt their vision to the denser medium of water, through which the rays of light pass to their eyes. Insects have great numbers of small eyes clustered together, and most probably they are of microscopic structure. Many of the inferior animals, as shellfish, worms, &c., have no eyes.

Hearing.—The ear is the instrument of this sense. The outer part of the ear is formed so as to collect and transmit the currents of air into the passage which leads to the drum. This passage is of a winding description, and, besides being defended at its mouth by a number of small hairs growing up in it, there is also a waxy substance constantly secreted, which keeps the whole moist, and is an effectual bar to the entrance of insects or other offensive substances. At the inner

* What may be called a *sixth* sense is almost if not altogether demonstrated, namely, the *muscular sense*, or that by which we are made sensible of the condition of our muscles, as acted upon, for the moment, by gravitation and the resistance of matter, in order to enable us by our powers of voluntary motion to command these muscles. Sir Charles Bell has thrown much light on this subject by his discovery of distinct origins for the nerves of feeling and motion, although they are found undistinguishable, in their substance, in the same sheath. Hunger and thirst are *sensations* also, and so perfectly different from all others, that they have been held by some to be the effects of a *seventh* sense.

end of this winding passage is the thin membrane or drum, which is stretched out on four small bones, and which, by its vibrations, conveys, through the medium of the nerves, the sensations of sound. There are also attached to these small bones several muscles, which, by their contraction and relaxation, modify the tension of the thin membrane, and prevent sounds from acting too strongly on it, or render it tighter, in order to be even sensible to feeble vibrations. Behind the cavity of the tympanum, or drum, there is another passage which leads from the ear to the mouth, called the *Eustacian tube*, the object of which is most probably the same as the holes in the common drum, to allow the air to escape from behind, and thus promote the vibration of the membrane of the tympanum; for it is found, that if such holes are not made in a drum, little or no sound will be produced; and in the human body, when this tube, leading to the mouth, is choked up by the inflammation of a common cold, deafness is produced. There is another cavity called the vestibule of the ear, covered over also by a thin membrane: on this membrane the nerves of hearing are expanded, and convey the sensations of sound to the brain. The sense of hearing is very acute in some animals, especially those that live by prey. In the lower orders of beings the sense is wanting, but is compensated in a considerable degree by the extreme acuteness of feeling, or touch, which is so diffused over their bodies as to make them sensible of the least agitation in the air by which they are surrounded.

Smell.—The nose is the instrument of smell, and is of comparatively simple structure. The bones forming its inner cavity are of a spongy nature, or rather are composed of a number of very thin plates, covered with a soft membrane, over which the branches of the nerves of smell are minutely exposed. The effluvia proceeding from bodies, and which imparts their peculiar odour, must pass in a stream or current through the nose before the odour is perceptible. If the air is perfectly still, and no current allowed in the nose by suspending the breathing through that organ, the strongest smells will make no impression. In some animals the sense of smell is acute and powerful, beyond the conception of human beings; thus a dog, by the acuteness of this sense, will distinguish the footsteps of his master amid those of a hundred other people, and can thus trace him for miles, although he has been a long while out of sight; pointers also scent game at a great distance. On the other hand, this sense is entirely denied to many of the lower animals. In man it is in many cases very imperfect, and may be blunted, or even extinguished, by disease. In colds affecting the delicate membranes lining the nostrils, the smell is very much diminished.

Taste.—The sense of taste is nearly allied to that of smell. The nerves of taste are spread over the upper surface of the tongue, and are raised up in innumerable small points, like the pile of velvet. In the lion these papillæ are very large, and easily distinguishable. No other part of the mouth is endowed with the property of tasting, except the tongue, as may be proved by touching any part of it with a piece of salt or sugar, when no sensation of taste will be communicated until the tongue has come in contact with the part so touched. That the taste or flavour of many bodies is heightened by the accompanying effects on the organ of smell, is evident; because, if the nose is stopped up so as to prevent the exercise of its functions, many substances having different flavours will taste alike. This is the case with the various kinds of wines, but especially with the ardent spirits. It is almost impossible to distinguish between the flavours of different kinds of spirits if they be tried in the dark, and with the passage to the nose accurately shut up. The tongue and whole cavity of the mouth and throat are kept moist by the saliva, or spittle, which continually flows into them from repositories placed around the cheeks and under the tongue, called salivary glands, which communicate with the mouth by means of small ducts. This saliva flows in greatest quantity during meals, and may even be

excited by the sight of food when the appetite is good. It is of essential service in moistening the food, and preparing it for the process of digestion in the stomach. The sensation of taste is in all probability diffused among every class of beings, however low in the scale of existence, although it is probable many animals possess little of it in their mouths, especially when these are formed of hard, horny, or even earthy substances, as in many insects—the lobster, crab, &c.—and where any organ corresponding to a tongue is wanting. Even many birds that feed on grain and hard bodies, not chewed or broken down in the mouth, must have little sensation of taste.

Touch.—The sensation of touch is diffused more or less over every part of the body, but is most perfect at the points of the fingers, which in man are generally used to examine the figure and texture of bodies. For this purpose they are furnished with a large supply of very minute blood-vessels and nerves. It would appear that there are different nerves that convey the sensation of touch, distinct from those which are the nerves of motion; and that these proceed in pairs from the spinal marrow; and that, moreover, the sensation of heat or cold may be perceived very distinctly, in cases where the pricking of a needle or contact of other bodies is never felt. The sense of touch may be said to belong to every animated being, and is one great characteristic of animal existence. Vegetable bodies possess a certain degree of life, and show what is called irritability of their fibres; but they have no sensation, properly so called; they are not sensible of pain or injury, as the lowest and simplest sentient animal is; neither have they the compensating perceptions of pleasure. It is probable, however, that sensation is not by any means equally acute in all animals; some feel more intensely than others, and it is a happy provision of nature that it should be so. The lower insects and reptiles, from their structure and habits, are continually exposed to injury; and did they feel it as acutely as the larger animals, the degree of animal suffering throughout nature would be excessive. Many animals bear the loss of limbs with impunity, and have the power of restoring these lost members in a very short time. It is probable that, according to the perfection of the nervous system, is the acuteness of animal sensation.

On thus reviewing the different parts of the human body, it will be observed that most of its organs are double. On a line being drawn in the middle, on each side will be found parts which are exactly similar to the corresponding side. This is the case with the brain, which is a double organ, having two series of nerves proceeding out from each side of it to go to the respective sides of the body. There are two eyes also, each reflecting a distinct image on the retina; yet the nerves communicate so that only one impression is conveyed to the sense. The arms are double, to suit the various purposes for which they are employed, and so are the lower limbs, an essential requisite for the support of the body, and for progressive motion. The lungs, too, may be said to be double, having two distinct lobes; and it sometimes happens that one of them is entirely shrunk or diseased, and yet the important office of respiration is still carried on. The stomach, the liver, and some of the other viscera of the abdomen, are, however, single, their several offices being common to the whole body.

THE HAIR AND NAILS.

The hair grows out from the skin somewhat in the manner of a vegetable production. Hairs are fixed by roots in the skin, from whence, by a series of minute vessels, they draw nourishment, and continually increase in length. They possess no sensibility, however, and, unlike the other parts of the frame, may be cut off without producing the least pain. Hair is of different colours in different individuals—is fair in those of light complexion, and deep black in the swarthy. As old age approaches, and even in many young persons, where

there is a particular disease in the hair, or dryness in the skin, this colour changes to grey and white. The colouring matter of the hair is contained in the centre, which is of a hollow form, and consists of an oily substance, in which carbon or charcoal, in minute particles, is more or less mingled. The nails are somewhat like hair in their production and composition; they are, like hairs, insensible to the touch, and may be cut or pared without producing pain. They receive nourishment from the blood-vessels of the extremities, and have a constant growth or renewal of their substance. Nails serve as a defence to the tender parts of the fingers; in animals they form formidable weapons of attack. The horns of cattle are exactly of the same nature as nails, and are chiefly composed of animal gelatine.

The manner in which the various secretions take place in the system, that are to form hair, nails, wax for the ears, blood, perspiration, &c., cannot but excite our admiration; for the whole is a chemical process of the most perfect kind, and such as art possesses no power to imitate.

THE SKIN.

An external compact membrane or skin covers the whole body. The outer skin, or cuticle, is unprovided with any blood-vessels or nerves, and consequently is insensible; in this manner it is well suited for a protection to the parts beneath; it is pierced by innumerable minute pores, which are the mouths of the exhalant vessels: it is thicker in the palms of the hand and soles of the feet than in any other parts of the body. Below the outer skin is a thin membrane, called the *rete mucosum*, which, assuming different hues in different nations, gives rise to the variety of colour in the human race. Some have held this membrane to be double, but this is not established. In Europeans it is white, passing into yellowish brown; in native Americans, of a copper colour; in Negroes, of a deep black. The common belief is, that climate has the effect of modifying the colour of the skin, as the black skin only occurs in tropical regions, and it is found that there it is a protection against the scorching influence of the sun's rays. Negroes will remain cool and comfortable exposed to a sun which would be intolerable to a white-skinned person. Their free perspiration seems to be of great service. Immediately below this network is the *cutis*, or true skin, an extremely sensible membrane, so thickly studded with minute blood-vessels and branches of nerves, that the smallest-pointed needle cannot prick it without touching many of them. On the points of the fingers, lips, and other parts of the body, these vessels are very numerous; and hence these parts are endowed with exquisite feelings of touch. Below the skin is situated the cellular membrane, which is a network, whose interstices are filled with fat, and it thus serves to fill up the spaces between the muscles, and to make up the shape, and preserve the symmetry, plumpness, and beauty of the whole frame. In cases of emaciation, this fatty matter is sometimes entirely taken up by the absorbent vessels—as after a tedious fever or other lingering disease—when the rough outlines and indentations of the muscles, and the projections of the bones, become painfully apparent.

SLEEP.

The various functions of the body are divided into voluntary and involuntary. When we eat we perform a voluntary motion, but digestion is performed without the action of the will, or is involuntary. The whole interior functional operations are involuntary, and go on whether we are awake or sleeping.

As a constant supply of food is necessary to repair the waste of the grosser parts of the body, so sleep is essential for the repose and renovation of the finer and more subtle nervous energy. Mere rest alone will not recruit the animal frame, but sleep, or a profound oblivion of feeling and sensation, and of every external circumstance, seems essentially necessary at every

periodical revolution of the day. Toward the close of a day of exertion, the muscular powers which have been employed in motion, and in sustaining the body erect, begin to suffer particularly; the eyes become dim and heavy, and the eyelids close involuntarily; the lower jaw falls down; the circulation of the blood through the lungs is sluggish, hence frequent yawning is caused; the head nods forwards; all external objects affect us less and less; the thoughts become confused; and at last the profound oblivion of sleep ensues. We are unconscious of the exact moment when we pass into sleep, but occasionally it happens that immediately afterwards we are awaked by a convulsive start, which is caused by the sudden breaking in of the powers of volition, when as yet but newly and imperfectly lulled to rest. Sleep is quite essential to existence. Deprive a person of sleep, and the body sinks under the privation more rapidly than under famine. Indeed, no circumstances, however urgent, will prevent the approaches of sleep for any length of time; and under the severest calamities, and even while in the hour of battle, or when suffering from extreme fatigue, or cold, or hunger, sleep steals upon us to steep the senses in oblivion. Healthy sleep is so profound as to resemble, in all that regards self-consciousness, death itself. Sometimes, however, the mind exerts its activity, though it is but a partial exertion; and hence dreams, or thoughts of sleep, are made up of all incongruous associations, such as thoughts of the past day and incidents of long bygone years; scenes of actual experience, and others totally imaginary, being all mixed up and jumbled together. In sleep the heart continues to beat with regularity, and the circulation of the blood is carried on throughout the body; the lungs perform their functions, the stomach digests, and the bowels, and all the glands for secretion, carry on their operations; in short, every thing is carried on connected with the sustenance of the body and the existence of the vital powers; but for the most part all other powers, such as those over which we have a control in our waking hours, are at rest. This is not always the case, however, as walking during sleep, or somnambulism, is a peculiarity to which some individuals are liable. Dreams are most common when the sleep is imperfect or too long continued, and thus they occur frequently towards morning, or through the night, if the stomach is loaded and oppressed with food, or the mind harassed and deeply impressed with cares and solitudes. In a state of health and serenity of spirits, the most profound and most refreshing sleep is during the first period of the night. When asleep, the circulation and breathing are both somewhat slower than when awake, hence the animal heat becomes diminished; and this is the reason why more clothing is required in bed than during the day. This is the reason, too, why a person lying down to sleep out of doors, or on a sofa, with the usual allowance of clothes, feels chill and uncomfortable on awaking. Digestion, too, would appear to go on less vigorously during sleep; and hence the impropriety of going to bed with a full stomach. During the night and darkness is the most natural and obvious time to select for repose, and it is only the absurd encroachments of fashion that have well nigh turned day into night. By going early to bed, the damps and colds of night are avoided, which is of essential consequence, especially for the delicate. There is also a natural connexion of the functions of the body with the periods of day and night, which makes sleep taken in the first part of the night peculiarly refreshing. The absence of every irritation of the head and other parts of the body—the perfect rest of the mind and external senses—have also great influence in promoting sleep. Again, a variety of causes which weaken and debilitate the body, incline to sleep; such as great losses of blood, cooling medicines, purgatives, coldness of the atmosphere; and narcotics, such as opium and tobacco, drinking largely of wine or spirituous liquors, by first causing great excitement, and afterwards a corresponding debility of the system, also predispose to profound and lethargic sleep. Inju-

ries of the head, by pressing on or otherwise interrupting the functions of the brain, also induce sleep; and great corpulency, by retarding the return of blood through the veins, and thus keeping up a pressure upon the head, is generally accompanied by a disposition to sleepiness.

The period required for sleep, by different individuals, depends much upon temperament and peculiarities of constitution, as well as on mode of life and habit. While some cannot sleep beyond five, six, or seven hours, others, again, cannot well do with less than eight or nine hours. Children sleep more than half of their time, and require it, and thrive under it; while adults need much less repose. On a general average, eight hours has been reckoned a good allowance. Certainly sleep beyond this does no good, and often does harm. In order to enjoy grateful and uninterrupted sleep, it is necessary that due exercise shall have been taken during the day; that temperance in food and drink shall have been observed; that strong tea or coffee, which have a stimulating effect on the system, shall not have been taken within an hour or two of going to bed; and that there has been no supper, or a light one. It is true, gluttony and intoxication produce sometimes deep sleep, but it approaches more to an apoplectic stupor than the calm repose of the temperate.

THE SEXES.

In almost all animals the sexes are distinguished by a difference of form and texture of their bodies; and in many a superior gloss of colour in the hair or fur, or a superior brilliancy of the plumage, very generally characterises the male of the species. In most animals, too, the males are of superior size, and endowed with greater muscular strength. In the human species man is marked by a larger and more muscular body than the female; his chest is square and capacious, and particularly at the shoulders, whence it tapers gradually downwards; his bones are large, and his joints firm and sinewy; his muscles are round, tense, and conspicuously marked; his limbs thick and fleshy, and his arms powerful; his skin is firm and tense, and his hair strong, crisp, and often curly. The female figure, again, is smaller, less powerful, and, in every respect, more delicately formed; the bones are less projecting, the muscles softer, less conspicuous, and more smoothly blended one into the other; the shoulders are narrow and rounded; the greatest breadth of the body being at the pelvis, from whence it gradually tapers upwards; the skin is soft and delicate; the hair smooth, and of a silken appearance. The mental qualities and dispositions differ somewhat also. Man is commanding, resolute, daring, adventurous, addicted to deep and abstract thought, as well as to high and imaginative speculations. Woman is gentle, submissive, timid; with a mind, perhaps, little inferior in compass to man, she is more commonly distinguished for acute penetration, nice and delicate discrimination, refined and chastened taste, and elegant and playful fancy. It was the opinion of Plato, that, with regard to the mind, there is no natural difference between the sexes, but in point of strength. "When the entire sexes are compared together," says he, "the female is doubtless the inferior; but in individuals, the woman has often the advantage of the man." With warm and tender attachments, pure morals, and high religious feelings, she is admirably calculated for the sacred charge of watching over and training up the young, and of instilling into their tender and susceptible minds the beautiful lessons of early wisdom—of faith, truth, and charity. All nations, as they have advanced in civilisation, have uniformly increased in that respect and refined attention which is due to the softer sex; and one of the most powerful minds and of the most splendid endowments has been the foremost to appreciate those superior qualities which are to be found in a gentle and unsophisticated female. The late Professor Dugald Stewart thus introduces a quotation from a well-known traveller, which affords a just and beautiful estimate of

the tender disposition of woman:—"From the greater delicacy of their frame, and from the numerous ailments connected with their temperament, combined with their constant familiarity with distresses which are not their own, the sympathy of women with the sufferings of others is much more lively, and their promptitude to administer relief, wherever it is possible, is much more eager than in the generality of men. To the truth of this remark every day's experience bears witness; and, from the testimony of travellers, it appears that the observation extends to women in all the different stages of society."

TEMPERAMENTS.

There are certain conditions of the bodily frame which evidently give rise to varieties of the human constitution, and which have been called temperaments. These have been peculiarly the object of attention to Dr Spurzheim, and others of the phrenological philosophers. As their views on this subject seem to us of a very clear order, a passage is here extracted from one of the journals devoted to that science. "Dr Spurzheim," says the journalist, "recognises four primary or cardinal temperaments, to which he considers all individual cases may be advantageously referred, either as pure, or much more frequently as consisting of two or more combined. I shall first give Dr Spurzheim's brief description of them, and shall afterwards enlarge upon each in detail.

1. The lymphatic, or phlegmatic temperament, is indicated by a pale white skin, fair hair, roundness of form, and repletion of the cellular tissue; the flesh is soft, the vital actions are languid, the pulse is feeble, and the whole frame indicates slowness and weakness in the vegetative, affective, and intellectual functions.

2. The sanguine temperament is proclaimed by a tolerable consistency of flesh, moderate plumpness of parts, light or chestnut hair, blue eyes, great activity of the arterial system, a strong, full, and frequent pulse, and an animated countenance; persons thus constituted are easily affected by external impressions, and possess greater energy than those of the former temperament.

3. The bilious temperament is characterised by black or dark hair, yellowish or brown skin, black eyes, moderately full but firm muscles, and harshly-expressed forms. Those endowed with this constitution have a strongly-marked and decided expression of countenance; they manifest great general activity and functional energy.

4. The external signs of the nervous temperament are fine thin hair, often inclining to curl, delicate health, general emaciation, and smallness of the muscles, rapidity in the muscular actions, vivacity in the sensations. The nervous system of individuals so constituted preponderates extremely, and they exhibit great nervous sensibility.

The pure lymphatic temperament is characterised by a pallid complexion, soft skin, mostly free from hairs, the hair flaxen, the pulse weak and low; a general tendency to corpulence, and a deficiency of expression in the face. Instances of pure lymphatic temperament are more rare than of either of the others, and perhaps are never to be found, except amongst females and habitual invalids, when past middle age, who, from the want of exercise, have lost all trace of some other temperament which they may have possessed in youth. The mental characteristics of the lymphatic temperament are soon told; an insurmountable tendency to idleness, an aversion to exertion of either body or mind, form the hopeful traits. It is, therefore, obvious that the restraining faculties, Cautiousness and (in some of its manifestations) Secretiveness, are the only organs with the operation of which it will correspond; while all the other propensities, and the intellectual faculties, will be enervated and restrained by it.

It has been generally supposed that the sanguine constitution is produced by the perfection or redundancy of the circulatory system; and it seems such a natural supposition, that it is difficult for us to allow its

proper force to the fact, that individuals of other temperaments are frequently found who can bear loss of blood, by phlebotomy or otherwise, as well as those of sanguine constitutions, and in many instances much better. There is, however, one anatomical peculiarity which appears always to attend the sanguine. The skin is much less disposed to transpiration than the bilious or nervous; and, in consequence, Dr Prichard, in a work lately published, considers that individuals possessing it are much better calculated to bear cold than others. The Fins, who, as a nation, are decidedly sanguine, bear extraordinarily cold winters much better than their more bilious neighbours the Laplanders. Dr Prichard adds, that as the sanguine temperament is very rare in those warmer countries, near the spot where man was first placed by his Creator, he considers the sanguine temperament as the result of a natural adaptation to external circumstances, analogous to the white hares and other animals of northern regions; but, if this is the case, it is difficult to imagine how it is that Laplanders should continue tawny, while the Fins, situated farther south, are fair. The most striking moral feature of the sanguine temperament appears to be a tendency to enjoyment of the present time, with little inclination to regret the past or to dread the future; and, in general, to look at either past or future no more than is accessory to happiness. The bilious temperament is characterised by a decided cast of features, complexion inclining to brown, dark eyes, and black or dark brown hair, with the muscles firm and well marked, and the figure, in general, expressive of vigour, with every motion significant and decided. In combination, it is frequently traced in a slight yellowness of the skin, which can only be detected by comparison, or an extraordinary acute perception of colours; for example, you may frequently find two persons, particularly ladies, the one with dark hair and eyes, the other with flaxen hair and blue eyes. The complexions of both would be denominated fair; on observing them near each other, however, it will be seen that the fairness of the dark-haired one differs considerably from the clear snowy whiteness of the sanguine.

With respect to the nervous temperament, it manifests itself in a remarkable quickness to learn and readiness of comprehension, but little tendency to sensual gratification, and an extraordinary power of passing from one subject to another."

MAN ADAPTED TO LIVE IN ALL CLIMATES.

Man has this superiority over all other animals, that he can inhabit every different region of the globe, however extreme the degree of temperature. He is found under the scorching sun and amid the arid plains of Africa, as well as in the frost-bound regions of Spitzbergen; and he is found to live and thrive under these different extremes, not only after a gradual naturalisation of ages, but can even move from one country to another, and undergo a vicissitude of climate with comparative impunity. Thus we see, even from our own country, emigrants going forth, and naturalising themselves amid the cold regions of the north, onward to the very verge of the equator. The Esquimaux and the Canadian savage will prosecute their usual employments of the chase in a temperature where mercury freezes into a solid mass, and where even brandy congeals to ice in apartments containing fires; while the African negro, again, feels quite at his ease in a burning climate, where the thermometer in the shade ranges from 90° to 100°, and upwards. Man has an equal facility in adapting himself to the pressure of the atmosphere attendant on low or elevated situations. In Mexico, he is found living in elevated regions, from 6000 to 8000 feet above the level of the sea; and the hamlet of Antisana, in Quito, is 15,500 feet above the level of the ocean. On the contrary, we find almost all animals only adapted to live in the regions in which they are naturally found; and if they are removed from such localities, they seldom enjoy the natural period of their lives. Even the dog and the horse, the domesti-

cated companions of man, degenerate and change their natures under extreme varieties of temperature; and the monkey tribe, which, in the structure of their bodies and in the substances on which they feed, approach the nearest to man, become sickly and diseased, and never propagate their species, when removed into any of the colder regions of the globe. In order to enable man thus to subsist in regions having such a diversity of natural productions, he is endowed with the power of feeding on and digesting every possible variety of food—he is, as compared to other animals, in respect to diet, omnivorous. We thus find the Greenlanders and inhabitants of frozen regions living almost exclusively on the fat and flesh of land and sea animals, the only species of food which the barren and ungenial nature of the climate affords, but one, nevertheless, which, from its stimulating and nourishing nature, is the very best for enabling them to live under such an extreme depression of temperature. The inhabitants of hot countries, again, will be found living on rice, fruits, and other vegetable substances, which the warm and genial soil produces in abundance, and which, from their nature, are less heating and stimulating than an animal diet. In the intermediate and temperate regions, a mixed diet of animal and vegetable food is preferred. Much discussion has arisen whether man be more a flesh-feeding or herb-eating animal; experience demonstrates that he is equally adapted to become both—that he will live on an almost purely animal diet, as well as on one purely vegetable; although, were we strictly to compare the form of his jaws and teeth, and the general structure of his intestines, with those animals that live on nuts and other fruits, and farinaceous or mealy substances, as, for instance, the monkeys, the near approach of these to the human structure would indicate to us that at all events a farinaceous diet is the most suitable to his natural organisation. We thus find among all civilised nations that bread, and the grains and mealy roots, in some shape or other, have always a preponderance in every meal. But the art of cooking, which man resorts to even in the first dawnings of civilisation, enables him to change the nature of his various food, and to render it more suitable both for digestion and the purposes of nourishment, and thus gives him a wonderful superiority over all the rest of the animated world. Indeed, it is by this improved mode of preparing his food, perhaps, as much as by original strength and perfection of frame, joined to the other comforts of civilisation, that he is enabled to brave the vicissitudes of climate, and to prolong his life to a longer period than the great majority of other animals.

Man has been formed with a naked skin, with the evident intention that he should clothe himself by his own labour and ingenuity. Almost all the larger and more perfect animals have a covering of hair, of feathers, or of down, which is at stated periods renewed, and in some animals in greater length and abundance at particular seasons, to suit the variations of temperature. But man can always adapt his clothing to the climate he inhabits, or to the varying alterations of the seasons; and he can at all times, by his own industry, vary or renew his suits. Man, too, builds for himself a comfortable habitation, to protect him from the inclemency of the weather, and is not contented with a burrow under ground, or the casual shelter of the woods and coppices, as is the case with the animals of the forests. It is true the architecture of bees, and some other animals, is curious, ingeniously combined, and admirably suited to their necessities; but in comparative taste, splendour, or even convenience, how far are all these surpassed by the houses, and temples, and cities of mankind! Though man is naturally defenceless and unarmed, how soon does his ingenuity enable him to obtain a mastery over the beasts of the field and forest, and furnish him with weapons of defence against all his enemies! How soon does his ingenuity enable him to improve and cultivate the soil—to drain marshes, cut down woods, level mountains—to select and cultivate the best species of grain, and the most wholesome and

nourishing vegetables, for food—to invent tools and engines, by which he acquires a command over the sea and land, by which he erects bridges, constructs machinery, and launches the towering vessel upon the wide ocean! And, lastly, with what skill he constructs instruments of art and of science, by which he can examine and investigate the most minute objects of nature, as well as bring within his sphere of observation other planets and other suns in the vast dome of the universe!

INFANCY.

At the moment of birth, the infant begins to exercise an independent existence, whereas before it formed a part, and was nourished by the vessels, of its parent. A general similarity takes place in the embryo growth of most animals, and the familiar instance of the chick in the egg may be taken as an example. The egg is composed of a centre part, or yolk, and of the albumen, or white part surrounding it. In this white part, a small darker speck may be seen floating, from whence the first rudiments of the chick are derived. In a few days after the hen has sat on the egg to impart to it the necessary heat, a small whitish spot will be observed, which is the first rudiments of a brain; in a few days more, vessels will be seen spreading out from a central heart, and forming a network all around; gradually an appearance of a head is seen, with indications of brain and spinal marrow; the eyeballs next are formed, then the several parts of the viscera, the projections of the wings and legs, and lastly, the skin and rudiments of the future feathers. During these periods of incubation, the chick has been nourished by the yolk of the egg, which has gradually been absorbed by its vessels for this purpose. At last, when its growth is perfected, and the whole contents of the egg converted into the materials of its body, the little animal begins to pick a hole in the shell, and, by repeated efforts, bursts from its shelly prison, and assumes an independent life. The infancy of man is of much longer duration, and of a much more helpless nature, than the same state in any other animals. A child cannot walk till it is at least twelve months old; and even for a considerable time after that period, it has to be fed and tended with the utmost care; whereas, after a very short time, the young of most animals are able to provide for themselves; in a great many, a few minutes after birth they are able to walk about, to search for and distinguish the teat of their mother, and to pick up the food that is suitable for them; and having remained under their maternal protection for a short space, they leave their parents, and never know or distinguish them more. It is very different with the infant: during a long and helpless period of childhood, it is tended by a fond mother, who anticipates all its wants; while it, on the other hand, watches her smiles, and imitates her most minute actions; and thus a reciprocal bond of union is established, by which not only every species of knowledge and experience is acquired for the conduct of after life, but those moral ties and affections established which constitute the great boast and solace of human society. Man proceeds from infancy to maturity by a slower and more gradual expansion of the bodily structure than any other animal, and this may be one reason of his superior organisation, his greater fitness for supporting labour and fatigue, and the longer period to which his life is extended. From infancy upwards, the mental powers also gradually expand. This is also different from animals; for in them the faculty of instinct at once is perfected, and never afterwards increases or undergoes any change. In childhood, the mental faculties are constantly active, and on the alert to catch new information, inquisitive to know every thing, and imitate every gesture. The facility with which children acquire the knowledge of words, and in a few months master a language, is very astonishing, when we reflect for a moment how much time and pains it takes a grown-up person to become a proficient in any unknown language: and our astonishment will be heightened when we consider, that, in the case of chil-

dren, they have not only to acquire the words and their proper applications, but even to master the articulation of sounds, with all their infinite combinations. The age of puberty, or that period when boyhood terminates and manhood commences, varies somewhat in different climates, according to their high or low temperature; the mean period may be reckoned about fourteen years; and, between twenty and twenty-five, the growth of the body generally terminates. About the age of thirty, man may be said to be in his full vigour, with his mental and bodily powers completely developed. Females arrive earlier at a state of maturity than males: in warm climates females are full grown as early as their ninth or tenth year; in more temperate regions, about their fifteenth or eighteenth year. The proportion of male children born to that of females, is as 21 to 20; there is thus a small superabundance of males; but, from various causes, it so happens that there is generally rather a superabundance of females actually existing in society. Among these causes may be mentioned, the greater hardships and labours to which men are exposed, the effects of war, and, on the whole, the longer life enjoyed by females. This regular proportion of male and female births throughout mankind in all ages, and in all parts of the world, shows the admirable design and precision of an unerring nature.

OLD AGE.

We have seen that there is, within the animal frame, a system of operations, by which a constant supply of nourishment is afforded to make up for the daily waste and decay, and that every part is constantly undergoing a renewal. To view a man in the full vigour of life, then, we might suppose that, excepting accidents, he was calculated to go on, in the course of existence, for an indefinite period. The principle of life, however, seems to have limits set to its duration, beyond which it fails to keep in healthy motion the animal faculties. The apparatus of life is evidently destined but to last for a certain time. Old age creeps on apace, and the vital flame burns fainter and fainter, till at last it sinks in the socket, and is seen no more. The commencement of decay is perceptible even in youth itself. The child at first grows quickly, from the soft and yielding state of all its vessels; but gradually these begin to thicken and get harder—a greater proportion of earthy matter is adding to the bones. The extremities grow large, while the heart itself does not increase in an equal degree; hence the circulation becomes less and less quick, till the period of full growth. When the growth of the body can proceed no farther, a degree of fatness not unfrequently occurs. This proceeds from the superabundant nourishment produced from the food, which, from the impetus or force of the circulation being more lessened by the greater extension and resistance of the body, accumulates in the cellular textures and by the sides of the extreme vessels. In every part of the body, the induration produced by approaching age becomes conspicuous—in the bones now wholly brittle, in the skin, in the tendons, in the glands, in the arteries, and in the brain itself, which gets firmer and drier. Moreover, the arteries continue to get denser, narrower, and even shut up in their minute branches. At the same time, the nerves become more and more callous and insensible to the impressions of the senses, and the muscles to irritation; thus, the contractile force of the heart, and the frequency of its pulsations, are diminished, and, of consequence, every force which impels the blood into the ultimate vessels. The quality of humours is diminished in the denser body; the moisture which lubricates the solid parts every where manifestly decreases. Nor is the quantity of humours only diminished; they themselves likewise become vitiated. They were mild and bland in children; they are now acrid, salt, and fetid, and loaded with a great quantity of earthy matter. This circumstance of the superabundance of earthy matter is evident in the gouty concretions in the joints of old people,

in the frequency of stone, and in the arterial tubes, and even the heart itself, being frequently converted into real bone. The rigidity of the whole body, the decrease of the muscular powers, and the diminution of the juices, constitute old age, which sooner or later comes upon all men—sooner, if subjected to violent labour, or addicted to pleasure, or fed upon a too scanty or unwholesome diet; but more slowly, if they have lived quietly and temperately, or if they have removed from a cold to a moderately warm climate. There are three obvious divisions of human life—a period of youth, including the period before the age of 30; of maturity, from 30 to 50; and of old age, commencing about the period of 50 or 60. David speaks of the age of man being, in his time, only threescore years and ten, or in rare cases fourscore years, which may be reckoned the average limit of human existence. After the period of 50 or 60 years, varying of course in different constitutions, the marks of old age begin to make their appearance. The skin becomes more lean and shrivelled; the hair changes to a grey colour, or baldness occurs; the teeth drop out, and, in consequence of this, the lower parts of the face, about the mouth and jaws, incline inwards; the muscular motions of the body become less free and elastic—this is especially seen in walking, old people generally treading on the whole base of the feet, and hence having a shuffling gait; the blood circulates slowly; the animal heat is diminished; the pulse occasionally intermits, and the whole energies of the animal frame become lessened; the eyesight begins to fail, and dullness gradually comes over all the senses; the memory undergoes a remarkable change—while recent events pass through the mind and make no impression, the occurrences of early life continually suggest themselves, and are minutely called to remembrance.

Although usually seventy years is the extreme period of human life, yet a small proportion of those born ever reach even this; a few rare instances occur where one hundred years or upwards are attained. The famous Parr lived to the age of 159 years; he married at the age of 120, and, when 130, was able to thrash, and to do every description of farmers' work. He was at last brought from the pure air and the homely diet of the country, into the family of the Earl of Arundel, in London, where he drank wine and lived luxuriously. The sudden change of diet and circumstances, however, proved quickly fatal to him. Henry Jenkins, another poor man, lived to the astonishing age of 169 years, and retained his faculties entire. Some time ago, a statement appeared of the ages of the resident pensioners of Greenwich Hospital, which contained at the time 2410 inmates. Of this number, 96 had attained to or passed the age of 80; one only was above 100; 15 were 90 or more; and 80 were 80 or upwards. About 42 of the 96 were of aged families, and in some of this number both parents had been aged. Longevity has in a great number of cases been found to be hereditary. Eighty of the 96 had been married; 79 were in the habit of using tobacco in some form or other, and 48 had drunk freely; 20 were entirely without teeth; 52 had bad, and 14 good teeth. But the oldest man in the house, who was 102, had four new front teeth within the five preceding years. The sight was impaired in about one half, and hearing only in about a fifth part of the number. Old people are not generally inclined for much exercise, nor is it suited to their stiff joints and impaired vigour; for the same reason they cannot endure much cold. Cheerful company, especially the company of the young, is peculiarly grateful to old people. Innocent amusements and recreations are also of great consequence, and the mind should be exercised in some useful or amusing pursuit. Cities, or at all events constant and agreeable society, are favourable to the condition of old age. In lonely secluded country places, the mind sinks prematurely into a total gloom and blank, for want of sufficient stimulus and variety to keep up the vigour of thought and play of ideas. Few deaths occur from what is commonly

called old age, or a gradual and simultaneous decay of all the functions. It may be said to happen when the powers gradually decay, first of the voluntary muscles, then of the vital muscles, and, lastly, of the heart itself; so that, in an advanced age, life ceases through mere weakness rather than through the oppression of any disease. The heart becomes unable to propel the blood to the extreme parts of the body; the pulse and heat desert the feet and hands, yet the blood continues to be sent from the heart into those arteries nearest to it, and to be carried back from them. Most commonly, however, some one part gives way, and disease gradually coming on, cuts off the lingering flame of existence. Thus the body, after having grown up to maturity, and flourished in its prime, sinks to the earth, and moulders into the elements of which its several parts are composed.

CONCLUSION.

The admirable structure of the body of the human being—its superiority in every respect to that of the lower animals—afford a most perfect proof of design in the all-wise Creator, and is one of the most striking instances of the impossibility of our formation being the result of blind chance. Paley, after going over a great number of examples of this kind of design in a Creator, proceeds to state that, in all "instances wherein the mind feels itself in danger of being confounded by variety, it is sure to rest upon a few strong points, or perhaps upon a single instance. Amongst a multitude of proofs, it is *one* that does the business. If we observe in any argument (he continues) that hardly two minds fix upon the same instance, the diversity of choice shows the strength of the argument, because it shows the number and competition of the examples. There is no subject in which the tendency to dwell upon select or single topics is so usual, because there is no subject of which, in its full extent, the latitude is so great, as that of natural history applied to the proof of an intelligent Creator. Perhaps the most remarkable instances of mechanism in the human frame are—the pivot upon which the head turns, the ligament within the socket of the hip-joint, the pulley or trochlear muscles of the eye, the epiglottis, the bandages which tie down the tendons of the wrist and instep, the slit or perforated muscles at the hands and feet, the knitting of the intestines to the mesentery, the course of the chyle into the blood, and the constitution of the sexes as extended throughout the whole of the animal creation. To these instances, the reader's memory will go back, as they are severally set forth in their places; there is not one of the number which I do not think decisive; not one which is not strictly mechanical; nor have I read or heard of any solution of these appearances, which in the smallest degree shakes the conclusion that we build upon them.

The works of nature require only to be contemplated. When contemplated, they must ever astonish by their greatness; for, of the vast scale of operation through which our discoveries carry us, at one end we see an intelligent Power arranging planetary systems, and, at the other, concerting and providing an appropriate mechanism for the clasping and reclasping of the filaments of the feather of the humming-bird. We have proof, not only of both these works proceeding from an intelligent agent, but of their proceeding from the same agent; for, in the first place, we can trace an identity of plan, a connexion of system, from Saturn to our own globe; and, when arrived upon our globe, we can, in the second place, pursue the connexion through all the organised, especially the animated, bodies which it supports. We can observe marks of a common relation, as well to one another as to the elements of which their habitation is composed. Therefore one mind hath planned, or at least hath prescribed, a general plan for all these productions. One Being has been concerned in all."

VEGETABLE PHYSIOLOGY.—BOTANY.

GENERAL ECONOMY OF VEGETATION.

EVERY one is acquainted with the usual forms of vegetables, either as herbs or trees; for they exist in all situations suitable to their growth, and constitute not only a highly ornamental covering provided by nature for the exposed surface of the earth, but, as is well known, are an inexhaustible source of nourishment to the animal races.

Plants are in the main easily distinguishable from animals, and the consideration of them falls under different sciences. Yet it is not easy to say where the animal world ends, and the vegetable world begins. The two seem to melt into each other in the class of existences called *zoophytes*, which appear a combination of both plant and animal.* We are not, however, to suppose that the highest class of plants are thus connected with the lowest or simplest class of animals, and that the organic world is consequently one continuous chain. The two systems may be rather said to be united at a point near the base of both, above which they rise side by side. Apart from this connexion, plants are to be distinguished from animals by not only certain external appearances, but by the absence in them, of what animals possess, an *internal principle* not easily described, but traceable in certain very remarkable results, namely, motion from place to place, a selection of advantageous circumstances, and a power of adapting means to ends.

Of the nature of life, or the vital principle, science does not profess to be able to give an explanation. In using the term, we only mean that power or quality resident in certain structures, by which they are enabled to incorporate with themselves those nutritive particles of matter which they require, and to reproduce structures of their own species or type. The most simple forms of life are observable in plants whose economy is limited to mere absorption of nutrition and reproduction; and it is only when we reach the link that unites vegetables with animals, that we find any thing sensitive, a nervous energy, or spontaneous locomotion. With respect to the powers of reproduction, it must be carefully impressed, that neither plants nor animals come into existence without a parentage. It was at one time supposed that some kinds of animals, as, for example, maggots, locusts, and myriads of smaller creatures, were produced from external causes alone, such as putridity or a certain state of the atmosphere; but such notions have long been abandoned by men of science, and it is placed beyond the possibility of doubt that all animals and vegetables whatsoever, notwithstanding any mystery that may attach to their appearance, are the offspring of others of their own type.

The method of reproduction, as will be afterwards shown, is different in different plants, but, as a general

principle, it may here be stated that the parent vegetable is charged with the function of liberating germs or seeds, which vegetate as soon as brought into a condition fitted for their growth. A seed is like an egg in character, for it possesses in itself that amount of nourishment which will enable it to subsist in the ground during germination, or until it draws the means of existence from the soil and atmosphere. Most kinds of seeds, being contained in husks or shells for their preservation, are able to retain their vegetative power for a long period of time, if entirely excluded from heat, air, and moisture; thus, on turning up soil which had been covered centuries ago, a new order of vegetation is always observed to arise from the long-buried seeds.

It may be further mentioned, as a provision in the economy of vegetation, that, while each species of plants is incapable of being transformed by reproduction into any other, it is possible, in some instances, as in the animal species, to produce a hybrid or mixed breed, and, with the additional means afforded by cultivation, plants and fruits may be improved in quality to a very high degree. Thus, the common sour crab, growing wild in our fields and hedges, is the uncultivated original of the different varieties of the apple. Yet, to sustain this improvement, constant culture, transplanting, crossing, or grafting, are required. The plant is only improved as respects itself, and if its seeds be allowed to grow up without culture in a poor soil, they will produce plants exactly resembling their humble original.

The term of vegetable existence, from the period of germination till the final decay of the plant, is extremely various: some plants are annuals, or grow but for one year or season; while others are perennial, and continue their growth from year to year; trees are among the longest lived plants, some being known to exist for upwards of two thousand years. The reproductive powers of plants are likewise very varied; but it may be stated in general terms, that in each case nature has provided effectual means of perpetuation, either by means of roots or seeds, or by both. This power of reproduction is strikingly observable in such plants as the potato, which propagates by oviparous seeds pendent from the stalks, and by the tubers clinging to the roots in the ground. In most instances, the artificial deprivation of the seeds before they arrive at maturity, incites the reproductive powers of the roots, and they increase in bulk, or throw up new plants at a distance from the parent stem. When annuals have ripened their oviparous offspring (grain in the ear, for instance), the object of their growth is accomplished, and they forthwith droop and decay.

The development of vegetable life is greatly dependent on certain concurring agents, among which, in a particular manner, are included *heat, air, moisture, light, and soil*. Each of these agents, however, is limited to a certain range, and this range is different in different plants,

* See ZOOLOGY, Number 34, in the present series.

so that excessive heat and excessive cold, and also the extremes of drought and of humidity, are always unfavourable to vegetation generally, though not to all kinds of vegetables. Thus some mosses and other plants, whose parts are few and little developed, continue to grow in very cold weather, and even under the snow; others, which generally contain much juice in their substance, but which are covered with an epidermis so compact that it resists the action of heat, and prevents any evaporation of the juice of the plant, live in situations where the heat is extreme, and during that part of the year when excessive drought renders the common vegetation as inactive as it is in polar countries during the depth of winter.

The condition of the atmosphere as respects temperature, moisture, and other qualities affecting vegetable life, is comprehended in the term *climate*. No two places at a distance from each other can be said to have the same climate, because each is subject to particular influences not affecting the other to the same degree. That district will possess the most genial climate, and be best adapted for the perfection of vegetable life, which at once lies most fair towards the sun, and is exposed to the action of refreshing rains, or is moistened in some other way. A free exposure to the sun throughout the year is equal to several degrees of latitude nearer the equator, other circumstances being favourable. The more free the exposure, the more readily will most plants blossom, and yield a rich fruit; so well is this understood in the grape countries on the Rhine, that the right bank of that river, which faces the sun, is reckoned to be much more valuable than the left, and commands a higher price for its wines.

The character of the vegetation in tropical and extreme northern and southern climates, is of the most opposite kind—the one luxuriant and continuous, and the other only for a short period during summer. In the tropical regions there is always about twelve hours of sunshine, and nearly the same length of darkness; and when the air is clear, the action of the sun is generally sufficient to occasion a suspension of the powers of many vegetables, or what is sometimes called a *sleep of plants*, during the heat of the day. But, unless for local circumstances, the chief of which are alternate successions of drought and rain, there is nothing in the mere solar action which can affect vegetation there very much more at one time of the year than at another; and therefore, considered with reference to the sun alone, the vegetation there is not only generally ever-green, but ever-growing, ever-flowering, and ever-ripe and in fruit.

In the extreme northern and southern latitudes, a portion of one half of the year is continual day, and a corresponding portion of the other half continual night; and when the continual day approaches, if part of the heat of the sun were not occupied in melting snow and ice, and turning into vapour the water which clouds the atmosphere and mitigates the ardour of the solar heat, the action of the sun in those high latitudes would at these times be excessive. As it is, vegetation, during the short period that it acts, is more vigorous in such parts of the polar countries as are out of the range of the cold produced by melting snow or ice, than it is in any other part of the world; and even in Lapland, we have the expansion of the bud, the blowing of the flower, the ripening of the fruit, and the preparation of the new bud, in little more than half the time in which these operations take place in the temperate climates. This state of things requires a suitable character in the vegetables placed in those countries—they must be capable of resisting equally the ardour of summer and the rigour of winter. For this purpose, such vegetables as stand exposed to the air at both seasons, form complete buds, encased in a hybernaculum, composed of a number of scales of a resinous or gummy consistency, with thin strata of dry air between them; and buds so shielded are proof against the utmost severity of cold. The more lowly plants of

such places are defended by the snow which covers the ground; and thus, though the action of the vegetable world is limited in its annual period, and also in the number of species in which it is displayed, it is as perfect in its system, and as secure in its continuance, as in the tropical regions. Between these extremes, there is a regular gradation; and taking that and local observation along with us, we are in possession of at least the elements upon which a geography of plants may be formed.

While heat, variously modified, serves as a prime exciting cause of vegetable life, air and moisture or water are elements on which the vegetables feed and exist. The soil in which the plants have their roots, and the atmosphere in which their branches and leaves flourish, are the great laboratories of nature whence these elements are drawn. To understand properly how plants derive nourishment from these sources, it is necessary to appeal to *chemistry*, or that branch of science which recognises the elementary properties of matter. The following are a few leading principles, briefly stated:—

“The substances which constitute the principal mass of every vegetable, are compounds of carbon with oxygen and hydrogen in the proper relative proportions to form water. Woody fibre, for example, is composed of such compounds of carbon with the elements of water. In another class of substances containing carbon as an element, oxygen and hydrogen are again present; but the proportion of oxygen is greater than would be required for producing water by union with the hydrogen. The numerous organic acids met with in plants belong, with few exceptions, to this class. A third class of vegetable compounds contain carbon and hydrogen, but no oxygen, or less of that element than would be required to convert all hydrogen into water. These may be regarded as compounds of carbon with the elements of water and an excess of hydrogen. Such are the volatile and fixed oils, wax, and the resins. The juice of all vegetables contains organic acids, generally combined with inorganic bases or metallic oxides; for these metallic oxides exist in every plant, and may be detected in its ashes.”*

Nitrogen also forms a portion of most plants, being an important ingredient in the substance called gluten, or the starchy material of farinaceous vegetables. It is chiefly drawn in the form of ammonia from the soil to which animal manures have been applied. In general, carbon is the fundamental and principal element in plants, and this is derived chiefly from the atmosphere. The carbon exists in the atmosphere in the form of carbonic acid, or in a state of union with oxygen; and therefore, before appropriating the carbon, plants must necessarily decompose the atmosphere. This process is actually performed by the vegetable kingdom. Plants possess the power of separating the carbon of the carbonic acid from the oxygen, and, seizing upon the carbon, return the oxygen to the atmosphere.

The process of decomposition and appropriation is performed by the leaves and other green parts of plants, these constituting the breathing apparatus. But, for the performance of this remarkable chemical action, aid from the sun's light is necessarily required. While vegetables are in a considerably darkened shade during the day, and in darkness during the night, carbonic acid is accumulated in all parts of their structure; and the assimilation of the carbon and the exhalation of oxygen commence from the instant that the rays of the sun strike them. As soon as a young plant breaks through the surface of the ground, it begins to acquire colour from the top downwards, and the true formation of woody tissue commences. Plants thus improve the air by the removal of carbonic acid, and by the renewal of oxygen, which is immediately applied to the use of man and animals.

The growth of plants, and their transformation of elementary properties in the soil and atmosphere, must

* Leibig's Organic Chemistry

hence be regarded as a protracted and various process in the chemistry of nature, proceeding on fundamental laws. In order that the process may not be defeated, pure atmospheric air, and also the sun's light, must be allowed in their proper proportions, independently of pure water. The air best adapted for robust vegetable growth is that of an ordinary density, near the sea's level. Generally speaking, the more elevated the station of the plant is, its action is the less, because the air is less dense, therefore colder, and is understood to have greater evaporative power; but mountainous countries are generally much better supplied with humidity than plains; and therefore the dwarfed growth of plants in such situations must be considered as resulting much more from their diminished action than from any excess of evaporation. Hence, as we ascend the slopes of mountains which are of sufficient elevation for having their summits covered with perpetual snow, we find upon them plants resembling those of a succession of latitudes, gradually getting colder than the mean temperature of that which answers to the level of the sea, in the same latitude as the mountain. So that, upon very lofty mountains near the equator, the Andes in upper Peru, for example, we meet with something resembling the succession of plants in the whole quadrant, from the equator to the pole. But it is a resemblance only, and not an identity; because, although it be possible to find upon the side of such a mountain places which have the same mean temperature for the year as is found in every parallel of latitude, yet both the daily and the seasonal distribution of the sun's action are very different; and it necessarily follows that the habits, and even the characters, of the vegetables are equally so.

Humid air supplies some vegetables with all the nourishment which, from their situations, they can possibly obtain; and therefore we may conclude that it is capable of affording some nourishment to every vegetable. But the air also acts as a drain upon vegetables, in removing out of their structure a portion, and sometimes a very large portion, of that water which is necessary for the purposes of growth; and in proportion as the air is more humid, it must perform this function less perfectly. We must therefore suppose that there is a certain degree of moisture, and of evaporative power jointly, in the air, which is best adapted to the healthy action of plants; but what this is must depend upon the nature of the plant, and must therefore be ascertained by direct observation. Indeed, this is one of the circumstances which tends to the local distribution of the different kinds of plants, as we find them in a state of nature; but, like the others, we cannot so separate it from co-operating causes as to obtain the law of its action. There is one other circumstance connected with the air which is worthy of notice, and that is, whether it be more generally stagnant or in motion. It is perfectly evident that the action of stagnant air upon a plant must be every way less than that of moving air, whether we suppose the action to be of one kind or another; and therefore, up to a certain point, motion in the air must be favourable to the growth of vegetables. Of this there have been proofs by direct observation, in the same part of the world; and when we examine different parts of the world, we find proofs which are much more striking: thus, for instance, the trade wind of the Atlantic sets constantly against the shores of Brazil and Guiana, and up the valley of the Amazon, until its motion is gradually destroyed by the dense mass of vegetation over which it passes.

The Oriental isles, and the southern part of the Malay peninsula, are in like manner exposed to a constant current of the air; and those two regions are, in respect of the number, the variety, the beauty, and the activity of their vegetable productions, the very gardens of the two hemispheres. Even when the current of air is an alternating one, the return of which is actually unfavourable to vegetation, such a situation is still highly favourable upon the whole. Of this we have striking examples in the valley of the Mississippi, the

Malabar coast of India, and even in the British islands, and, generally speaking, along the whole of the west coast of Europe, where the advantage is not counteracted by some local cause.

Winds are therefore to be considered as performing an important part in the economy of nature. From northern and southern latitudes, where there is a small supply of sun's light during winter, with weak vegetation, and consequently a superabundance of carbonic acid in the atmosphere, the winds convey the deleterious material to tropical regions, where, by means of the brilliant sun's light and strong vegetation, it is readily and profitably consumed. Streams of wind in a contrary direction, or from the equator to the poles, in the same manner bring to us the superabundance of oxygen produced from tropical plants. While heat, moisture, air, and light, variously modified in the multifarious climates on the globe, produce the extraordinary diversity of vegetable growth, another set of circumstances affect the life of plants, and these relate to the nature of the soil in which they are placed. Although properly belonging to GEOLOGY, we shall present a short exposition of what soils usually consist.

The soil is mainly composed of particles which have been disengaged by various means in the course of time from the rocks on which it rests. In some instances, and more particularly on hills, it is composed chiefly of pulverised materials from the rocks immediately at hand or beneath; but in many others, the pulverised matter has been washed down from high into low grounds, or transported by floods from great distances. The action of the air and water on rocks in dissolving them, and the power of the latter element in transporting the disengaged particles, are the principal causes of the present arrangement of the soil.

Notwithstanding the different appearances which the earthy covering of the globe exhibits, it is composed almost entirely of four substances, formed by an original union of simple elementary matters. These four substances, washed at a former period from rocks, and more or less compact from influencing circumstances, are called primitive earths, and are named *clay*, *sand*, *lime*, and *magnesia*. Clay is variously named alumine or argillaceous earth; sand is sometimes termed *silex*, *silica*, or *silicious earth*; and lime is commonly called *calcareous earth*. The distinctive characters of all these substances are well known. Besides these four earths, which either in a soft or hard state constitute the soil and subsoil, the upper stratum or mould contains the relics of decayed vegetable and animal substances, also certain metallic bases, generally oxide of iron. The particles of decayed vegetable matter, sometimes termed *humus*, and known as food for new vegetation, are understood to be in reality a deposit of carbon gained by plants from the atmosphere. Ammonia, as already said, is also an ingredient in fertile soils.

The whole of these circumstances, modified in a variety of ways, influence vegetable growth, and require to be studied by the cultivator of plants. It has long been remarked, that plants have a tendency to exhaust the soil in which they grow, and to exchange their situation for one more suitable to their wants. The following propositions on this subject have been laid down by two eminent French chemists, Yvart and Piolet:—1. That every plant has a natural tendency to exhaust the soil; 2. That all plants do not exhaust the soil equally; 3. That all plants of different kinds do not exhaust the soil in the same manner; 4. That all plants do not restore to the soil the same quantity nor the same quality of manure; 5. That all plants differently affect the growth of weeds. From these fundamental principles the following conclusions are drawn:—1. However well a soil may be prepared, it cannot long nourish crops of the same kind in succession, without becoming exhausted; 2. Every crop impoverishes a soil, in proportion as more or less nutritious matter is restored by the plant cultivated; 3. Perpendicular rooting plants, and such as shoot horizontally, ought to succeed each other; 4. Plants of the same kind should not return

too frequently in a circle of cropping; 5. Two plants equally favourable to the growth of weeds ought not to succeed each other; 6. Such plants as greatly exhaust the soil, as grains, should only be sown when the land is in good heart; 7. In proportion as a soil is found to exhaust itself by successive crops, plants that are least exhausting should be cultivated. It may be added, that a successive change of crops has a tendency to destroy noxious insects, as those which are produced by one crop cannot be supported by another of a different description.

Nature, when unassisted, invariably makes an effort to change the crops of plants. When a forest in North America is burnt down by accidental fires in the summer season, trees of quite a different kind spring up from long concealed seeds in place of those which have been destroyed. When, in ordinary circumstances, one kind of plant has exhausted the soil in its neighbourhood, it pushes its roots to as great a distance as possible in quest of food, and there sends up shoots, while a new race of plants grows upon the spot which it has vacated. The seeds of certain plants, such as the dandelion, thistle, &c., are furnished with downy wings, by which they are rendered buoyant, and carried away from the parent plant by the slightest wind. The seed-vessels of other plants, such as the whin, when ripe, burst open with considerable force, and scatter the seeds to some distance from the place where the old plant grows. In these, as in a thousand other circumstances, we find that one of nature's great primary laws is that of perpetual change—an alteration from one condition and appearance to another, in endless succession and variety. In the artificial cropping of the ground, the farmer, for his own sake, is impelled to take a lesson from nature, and to study what species of plants he can most advantageously produce in succession from his fields. Hence, *aration*, or the *rotation of crops*, as it is differently termed, is a matter of first importance in husbandry.

A long course of experience and scientific inquiry have proved that all soils are capable of being improved by art, and supplied with restoratives suitable to the demands of the proposed vegetation. These artificial restoratives receive the name of *manures*, and are commonly in the form of animal excrements, these containing ammonia, one of the bases of vegetable structure, in greater or lesser abundance. Some idea of the powers of restoration from substances of this nature in a due state of putridity or decomposition, is obtained from the fact, that, from every pound of ammonia which evaporates, a loss of sixty pounds of corn is sustained. Potash, soda, gypsum, and other materials, also constitute manures, or bases whence are drawn fertilising principles in vegetation.*

CLASSIFICATION OF PLANTS.—LOWER FORM OF VEGETATION.

According to the latest researches of naturalists, about 80,000 plants of distinct specific forms have been discovered, but it is believed that as many more remain to be made known, and additions to the list are constantly taking place. For the sake of order and classification, as in the case of the Animal Kingdom, all plants, from the lowest to the highest forms of vegetation, are arranged in a progressive series of groups or families, the members of which possess a common resemblance, or are otherwise allied in character. This very necessary classification belongs to BOTANY—a term from the Greek, signifying a plant—and an outline of the plan adopted is given in the latter part of the present sheet. Here it is only necessary to mention, that, according to the Linnæan system, the whole Vegetable Kingdom is arranged in two grand divisions, namely, plants having visible flowers (*Phanogamia*), and plants having no visible flowers (*Cryptogamia*).

* To students who desire full information on this highly important branch of vegetable economy, and particularly all who are to be engaged in agricultural pursuits, we recommend the careful study of "Organic Chemistry," by J. Leibig; published by Taylor and Walton. London: 1840.

The whole are also divided into classes, orders, genera, and species, each species containing a number of varieties.

The lowest forms in which vegetables make their appearance are those of the *cryptogamia*,* among which are included the *fungi*, the *musci* (mosses), *hepatæ* (liverworts), *lichines* (lichens), *algæ* (sea-weeds), and *filices* (ferns), &c. The fungi, which may be placed at the very bottom of the vegetable scale, are observable in a great variety of forms, and, among others, mushrooms, toadstools, puff-balls, the fungous dry-rot, fermentation, mildew, and mould. We may take the last mentioned as about the lowest in the group. Mould, as most persons are aware, makes its appearance on the surface of various familiar objects—decaying paste, fruit-preserves, cheese, and old shoes. It never appears on any thing which is new or fresh, but is always a harbinger of decay, and may be considered a first step towards the decomposition of the substance into its constituent elements. How vegetation should appear in so secluded a situation as the inner cracks in cheese, or in a jar of preserves placed carefully away in a cupboard, or on the leather of an old boot in the remote corner of a bed-closet, is at first sight incomprehensible; but a consideration of the reproductive powers of fungi at once explains the circumstance. The whole of the fungous tribe possess the most extraordinary productive powers. Instead of propagating by the ordinary and slow process of elaborating and throwing off seeds, they increase by the dispersal of their entire substance. Every particle in their mass is a germ, or technically a *spore*, which, though smaller in bulk than a particle of fine dust, and generally so minute as to be invisible to the naked eye, is the embryo of a new plant, and will develop its powers of vegetation as soon as placed in an appropriate situation for its growth. In this manner, a toad-stool having performed its office and exhausted its means of nourishment, shrinks, dries, and dissolves in millions of atoms, which, being liberated and floated away in the atmosphere, are deposited in every imaginable situation. Some are inhaled into the lungs of animals, while others enter into the fabric of trees and herbs, and, in short, they find admission into every exposed and penetrable substance. It is, however, a distinct principle in fungous vegetation, that it can develop itself only in decaying bodies. Decay, or liability to decay, is necessary for its fructification; and when this condition ensues, and other circumstances are suitable, the embryo expands and rises with surprising rapidity into notice.

Large fungus.

A very remarkable kind of fungous vegetation is known to make its appearance in wine cellars, the substance which supplies the growth being the vapour from the wine in the casks or bottles. If the cellar be airy and dry, the vapour escapes, and no fungous vegetation is manifested; but if it be somewhat damp and secluded from air and light, the fungous growth becomes at once apparent. Round every cask a mould-like vegetation will exhibit itself, and the vapour from the casks rising to the vaulted roof, will there afford nourishment to great festoons and waving banners of fungi. In the wine vaults of the London docks, this kind of vinous fungi hangs like dark woolly clouds from the roof, completely shrouding the brick arches from observation. On a small piece being torn off and applied to the flame of a candle, it burns like a piece of tinder. Should wine escape from a cask in a moist and ill-ventilated cellar, it will altogether resolve itself into fungi of a substantial kind. A circumstance of this nature once

* A term signifying *hidden marriages*, or, by a liberal interpretation, plants whose means of reproduction are concealed, not obvious, as in the case of flowers.

came under the notice of Sir Joseph Banks. Having a cask of wine rather too sweet for immediate use, he ordered that it should be placed in a cellar to ripen. At the end of three years, he directed his butler to ascertain the state of the wine; when, on attempting to open the cellar door, he could not effect it, in consequence of some powerful obstacle. The door was therefore cut down, when the cellar was found to be completely filled with a firm fungous vegetable production, so substantial as to require an axe for its removal. This appeared to have grown from, or to have been nourished by, the decomposed particles of the wine, the cask being empty and buoyed up to the ceiling, where it was supported by the surface of the fungus.

The disease called rust, which affects grain in the ear, particularly in moist seasons, is well known to be a fungous vegetation, proceeding from germs which had previously existed in the substance of the plants. In a dry season, and on a favourable soil, rust rarely makes its appearance; certain conditions are necessary for its development, and it is to obviating these that the farmer must look for exemption from this destructive malady in his crops. It is now placed beyond a doubt that rust arises in many cases from the over-manuring of fields; the grain is overloaded with nourishment, and the dormant fungi, brought into a condition of development, speedily show their destructive properties. The tendency to rust may be neutralised by steeping the seeds before sowing in a corrosive solution, or strong brine, but the same end may be better secured by not over-manuring, or by a free use of saline manures. Salt, as is well known, is an enemy to corruption, and, when applied to the soil, it prevents the injury which plants receive from the fungus tribe. Skilful agriculturists are now fully aware of these facts.

Offensive in appearance as nearly all fungous vegetables are, and injurious as they may sometimes be to the crops of the husbandman, they perform a highly useful office in creation. Existing only by the absorption of foetid exhalations, and rapidly depriving them of their insalubrious properties, they execute duties analogous to those of certain tribes of insects (maggot-flies, for instance), and in this respect have been appropriately associated with these animals as the "scavengers of nature." On this point in their economy, a naturalist observes as follows:—

"The peculiarity of their agency consists in their power of suddenly multiplying their numbers, to a degree which could only be accomplished in a considerable lapse of time by any larger beings; and then as instantaneously relapsing, without the intervention of any violent disturbing cause, to their former insignificance. If, for the sake of employing on different but rare occasions a power of many hundreds or thousands of horses, we were under the necessity of feeding all these animals at a great cost in the intervals when their services were not required, we should greatly admire the invention of a machine, such as the steam-engine, which should be capable at any moment of exerting the same degree of strength, without any consumption of food during the periods of inaction; and the same kind of admiration is strongly excited when we contemplate the powers of insect and fungous life, in the creation of which nature has been so prodigal. A scanty number of minute individuals, only to be detected by careful research, and often not detectable at all, are ready, in a few days or weeks, to give birth to myriads, which may repress or remove the nuisances referred to. But no sooner has the commission been executed, than the gigantic power becomes dormant; each of the mighty host soon reaches the term of its transient existence; and when the fitting food lessens in quantity, when the soil to be removed diminishes, then fewer of the spores find soil on which to germinate; and when the whole has been consumed, the legions before so active all return to their latent unnoticed state, ready, however, at a moment's warning, again to be developed; and, when labour is to be done again, again to commence their work either in the same districts, or to migrate in

clouds like locusts to other lands. In almost every season there are some species, but especially in autumn there are many, which in this manner put forth their strength; and then, like the spirits of the poet, which thronged the spacious hall, 'reduce to smallest forms their shapes immense.'"

It will now be understood that mould is a fungous vegetation, produced by a previous deposit of germs in the tissue or on the surface of the object on which it grows. The proximate cause of its development is generally damp, and, without this condition, the embryo remains in a dormant state. Still, it may be asked, how cheese happens to have green mould at its very centre: the reply is, that the fungous germs floating in the atmosphere had various opportunities of finding admission into this article of diet. They may have been deposited on the grass of a field; the grass was eaten by the cow, and the germs were so lodged in the milk; or, what is more probable, the germs fell upon the curd, and there lay concealed till a certain dampness in the cheese brought their vegetative powers into operation. It is well known that the exposure of curd for a day to the atmosphere will have the effect of producing cheese liable to mould. The mouldiness of Stilton cheese is produced, we believe, by practising this device. Those who wish to make sweet cheese, not readily liable to mould, should avoid exposing the curd to the atmosphere.

A fully more surprising instance of fungous vegetation in a secluded situation, is that which occurs in the fermenting of yeast, and other substances. Fermentation is, in one respect, a chemical process, forming a first step towards dissolution, but the action is also vegetative. The whole mass of matter gradually assumes the condition of active vegetative growth. The fungous germs which had been incorporated in the material, begin to live and expand, each being a plant which grows and gives rise to new plants of the same species. A popular author observes of fermentation at this stage in its progress—"If a small portion of the fluid be examined at intervals with a powerful microscope, it is seen that each of the little vesicles contained in it puts forth one or more prolongations or buds, which in time become new vesicles like their parents; these, again, perform the same process: so that within a few hours the single vesicles have developed themselves into rows of four, five, or six. This is not the only way, however, in which they multiply; for sometimes the vesicles are observed to burst, and to emit a number of minute granules, which are the germs of new plants, and which soon develop themselves into additional cells. By the time that five or six vesicles are found in each group, the fermentation is sufficiently far advanced for the purposes of the brewer; and he then takes measures to check it, by which the vegetation of the yeast is suspended. The groups of vesicles then separate into individuals resembling those which first constituted the yeast; and thus, a greatly increased amount of this substance is the result of the process."*

We may learn from these observations that the germs of fungi, necessary to produce dry rot, mould, fermentation, and other species, are dispersed throughout all organic matter. Every thing we eat, drink, taste, or which ministers to our wants, contains the germs of fungi, and all that is required to bring them into visible operation are certain conditions of decay, heat, and moisture.

It is generally allowed that the algae embrace the most minute forms of vegetation (not of a fungous character). One of those forms is that which has vulgarly been called *red snow*, or *bloody rain*. A shower of red-coloured rain or snow is by no means a rare phenomenon in the northern parts of Europe, or within the arctic circle; and the tinging matter, which has been accurately examined, is found either to proceed from the incorporation of vegetables or animalcules, both too small to be seen by the naked eye. The colouring vege-

table matter is an aggregation of an infinitude of plants either sucked up by a water-spout into the atmosphere, or overtaken while carried along by the winds, and brought down by the falling drops. On the stones by the side of brooks, we may sometimes observe a similar reddish colouring matter, which, if not caused by metallic ores, will generally be found to be a primitive kind of vegetation. When touched, it feels slippery, and on examination by a microscope, it is observed to consist of myriads of plants, each consisting of a small vesicle or globule, which, on arriving at maturity, expands, bursts, and liberates plants of its own species. This excessively humble plant is classed with the algae, as being the nearest to it in character, although these plants are for the most part of a large size, and grow principally on rocks in the sea.

The object which nature has in view by the germination and dispersal of the algae, mosses, and lichens, is clearly that of preparing the way for a higher order of vegetation. It cannot possibly escape our observation, that the tendency to vegetate is a power restless and perpetual. We hew a stone from the quarry and place it in a damp situation, on the ground or in a wall, it is all the same which, and shortly a green hue begins to creep over it. This is the commencement of a vegetable growth, produced by germs floated in the atmosphere, and being attached at random to the stone, have been brought to life through the agency of the moisture. Other stones equally exposed, but in dry situations, have also received a clothing of these germs, but circumstances not being suitable, they have not been developed: give the moisture, and they will immediately appear. We hew another stone from the quarry, and build it into the pier of a bridge, just within the surface of the water. Shortly, the same kind of green algae will appear; but the wet being in greater abundance and more continuous, the growth will become more luxuriant. Instead of the simple green hue, we have the addition of long filaments resembling green hairs, which float and accommodate themselves to the water around. This kind of plants, which are known to naturalists as the *confervæ*, propagate, like others of the cryptogamia, by a rupture of their tissue, and the liberation of germs, which become plants of the same species. Of course there cannot be a doubt that all open ponds, lakes, and running waters, abound in germs capable of producing this green filamentous vegetation.

The inquiry may perhaps here be made—supposing that nature designs this species of growth to be a fore-runner of a higher order of vegetation, how is that result to be brought about? To answer this, we must take an expansive view of the subject, and not confine ourselves merely to one department of science. Nature is incessantly working out vast ends by humble and scarcely recognisable means. It seems to be a principle that nothing shall remain stationary or unchanged. The whole surface of our planet is every instant altering in its features. Mountains are being washed down into the plains, rocks are mouldering into soil, the sea is filling up at one place and encroaching on the land at another, and water-courses are constantly shifting their outlines. The duty of filling up seas, ponds, lakes, and rivers, is consigned to divers means within the animal and vegetable economy, and one of these is the growth of algae and other aquatic plants. Take a pond of water, and shut off its means of supply from rivulets and springs, and then observe what an effort nature will make to fill it up. The sides and bottom become speedily covered with a luxuriant crop of *confervæ*; other plants, which grow only in water, begin to make their appearance, their seeds being wafted thither by winds; at length the superficial matting of herbage is able to support the weight of birds, grass grows, there is alternate vegetation and decay, and finally the pond is filled up. This routine is observable in many small lakes which are fed by weak springs, and, except for an artificial clearing out occasionally, they would in a short time become dry land. What, indeed, are the extensive peat-mosses but lakes and pools clogged with vegetable matter,

which remains in a half-consumed condition. Thus we see that the green hair-like ooze which grows upon stones in the water, humble and apparently insignificant as it is, performs a distinct part in creation necessary to work out the important designs of providence.

Algae.

The algae are the vegetation of the deep, and grow as immense forests in the rocky bed of the sea, where they furnish food for animals, and assist in filling up and altering the channels. On being decomposed, they afford an alkali to soap manufacturers, and are exceedingly useful in furnishing iodine, a substance which is now used in medicine for reducing glandular swellings.

Lichens are a numerous family of plants, and put on various appearances. Their usual aspect is a dry scaly crust of a grey or yellow hue, and their appropriate place of growth is on old walls, gravestones in churchyards, and rocks; they are also seen growing on the trunks of old trees. Their structure is very simple;

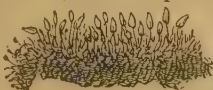

Lichen.

each plant consists of a membranous scale, or *frond*, divided into lobes, and they cling to the object on which they grow by means of small filamentous roots, which insinuate themselves into the most minute crevices. Growing usually as parasites on some kind of hard substances, they derive their nourishment exclusively from the atmosphere, and only require pure air and sun's light, with a fair proportion of moisture, for their subsistence. Their whole economy being rudimentary and simple, they are capable of living at great altitudes on mountains, where the air is too thin for the growth of the higher orders of plants; on this account the lichens are found flourishing beyond the limits of every other kind of vegetation, even to the very verge of perpetual snow. At these great heights they cannot be said to be of any service in preparing soil for plants of a superior order, but they at least help to bray down their rocky beds, and level mountains with the grounds beneath. From the atmosphere they have the power of secreting oxalic acid, which, acting chemically on their rocky base, causes small hollows, sufficient to gather rain from the atmosphere; and the moisture finding its way into crevices, the rock is split by frost, and in time moulders into fragments. The tenacity with which they adhere to their situation, renders it difficult to scrape them from stones by art; but as light and air are essential to their subsistence, they may be easily removed by covering them over for a short time with a turf or quantity of earth. Gravestones whose inscriptions have been obliterated by lichens, may by this expedient be completely cleared from their growth. Liverworts are a superior kind of lichens, possessing leafy fronds, and

expanding to greater dimensions; they also seem to grow best in situations somewhat damp.

In our comparatively mild climate, we have little experience of the lichenous family of plants, which appear to flourish best in those cold regions of the globe where almost every other living thing would perish. In the extreme northern parts of the American continent, there are found on the rocks a kind of lichen called by Canadian voyageurs *tripe de roche*, from its resemblance, when boiled, to tripe, and in which cooked state it forms a meal when more nutritious food is wanting. Another kind, called reindeer moss, is common in the arctic regions, where it grows to a foot in depth, and is the chief resource of the reindeer. The celebrated Iceland moss is also abundant in these regions, and may be reduced by cooking to a fine mucilaginous substance.

The name *moss*, however, is misapplied to these and most other lichens and liverworts. Mosses are plants a stage higher in structure and functions, and generally require a greater quantity of heat, air, moisture, and soil for their growth. With moss plants commence the rudimental characters of root, stem, branches, and leaves.

Moss.

Mosses have a bright green colour, a proof of the activity of their leaves or breathing apparatus; and their slender stems, with minute feathery branches, are among the most elegant structures of vegetable growth. Mosses fructify in a peculiar manner. On examining a soft green mass of moss, we may at certain seasons observe a forest of small thin stalks raised considerably above the general level. These are the seed stems. At the top of each is a small pouch containing the seed, and covered over with a lid or veil, which drops off when the fructifying matter is ripe, and suffers it to escape. By being elevated in this manner, and freely exposed to the wind, means are afforded of scattering the seeds over the recumbent moss, and for their being blown to places at a distance. The object seems to be, to keep up an active fresh vegetation on the surface of the moss, while a corresponding decay is going on beneath, and adding deposits of new soil. The whole economy of the plant is beautiful, and it will be remembered that it so much affected the feelings of Mungo Park, in one of his moments of desolation in the wilderness, as to inspire him with an energy sufficient to carry him over his difficulties.

HIGHER FORMS OF VEGETATION.—PHYSIOLOGICAL STRUCTURE.

From the humble class of cryptogamous plants, we ascend to the second great division in the vegetable kingdom, called the *PHENOGAMIA*, or plants which flower, and possess the attributes of distinct seeds, roots, stems, branches, and leaves.

Seeds.—A seed, upon being placed in the ground, in due time sends forth two shoots, one ascending and forming the stem, and the other descending and forming the root. The annexed figure gives a representation of the germination of a dicotyledonous or two-lobed seed: *a a* the seed lobes, *b* the leaf-germ, *c* the root spreading into fibres.

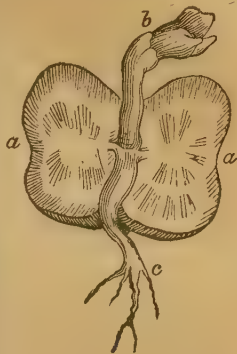

The time required for vegetation varies much in different species; thus the mustard takes little more than one day, whilst the rose, the hazel, &c., require two years. When a seed begins to germinate, it enlarges until it bursts its shell. As soon as the embryo stem has reached the open air, its leaflets are expanded, and begin to perform all the functions of leaves.

Roots.—The root (*radix* in Latin) is commonly defined to be that part of a plant which attaches itself to the soil where it grows, or to the substance on which it feeds, and is the principal organ of nutrition. Exceptions to this definition occur, as in the case of some vegetables which grow floating loosely in water, as duckweed and others, having no root at all. As the nourishment of a plant is derived from the earth, the root is that part which grows in an opposite direc-

tion to the stem, and is buried in the ground. A root consists of several parts, which have been called the body or *caudex*, the collar or life-knot, the branches or radicles, when such exist, and the rootlets or small fibres, which seem to be indispensable in all roots.

The body of the root assumes various forms; it may be globe-shaped, as in the turnip; conical, or tapering gradually from the collar to the attenuated fibre, as in the carrot; fusiform, or tapering at both ends, as in the radish; this latter may be abrupt, that is, as if the lower end had been cut off, exemplified in the devil's bit scabious; fibrous, or consisting of small thread-like fibres, which proceed directly from the collar, as may be seen in most grasses; tuberous, when the fibres bear globe-shaped bodies filled with starchy matter, as in the potato; fasciculated, when the fibres swell slightly in the middle; bulbous, when the round lobe consists of coats or layers, such as may be seen on cutting an onion across. A corn is similar in form to a bulb, but is not composed of layers; a palmated root consists of a number of oblong tubers proceeding from the collar, like the fingers from the body of the hand, as in the dahlia. Tuberous roots, such as the potato, are considered by some modern botanists as merely underground stems, from the circumstance of their having eyes, or buds, from which branches will spring. The crown, collar, or life-knot, as it is variously called, is that part which lies between the stem and the root. It is the most essential portion of the whole; for, if it be removed or seriously injured, the plant will inevitably die; whilst the small fibres or rootlets, although an essential part of a plant, may be destroyed at pleasure so long as the crown remains, for it readily reproduces them. When it is of a slender make, as the seeds form, it dries up, and the plant soon dies. Such plants are termed annuals, as the poppy, mignonette, and others. The crown, however, in some cases, by proper treatment, may be rendered so strong that annuals can be brought to grow two years, when they are termed biennials; or for three years, when they are called perennials. The fibrous root consists of a quantity of long thin fibres, of different lengths and thicknesses, and having still finer ones springing from them, as in the case of wheat, barley, and most grasses. These small fibres or rootlets bear a resemblance to the branches and leaves of the stem. Fibrils consist of a central fasciculus of vessels, enclosed by a cellular cortex and cuticle. Like the leaves of trees that are not evergreen, they are annually produced; in some cases dying and falling off like leaves, in others becoming thicker, harder, and forming radicles or root-branches. The spongelets, as they are called, which take up nourishment from the soil, are situated at the extremity of these rootlets. They are minute spongy bodies, of an oblong shape. We have an instance of rootlets falling off like leaves in those arising from bulbs—such as the lily, the onion, the tulip, &c., which are pushed off and perish like leaves by buds containing the rudiments of the rootlets to be evolved next season.

Roots have a remarkable tendency to grow downwards, or in the direction of the earth's centre, and, from experiments, it is likely that this tendency is an effect of gravitation. The precise direction, however, is very much influenced by the condition of the soil. Both root and rootlets extend as if in quest of food, and this will penetrate sideways or obliquely to great distances. When plants are by any means prevented from fructifying by seeds, they almost invariably increase by extending their roots, from distant points of which new plants will spring up.

The stem or stalk.—When a plant shows itself above the ground, it evidently manifests a strong tendency to the light. Light, in fact, is essential in bringing it to maturity, and in giving the green colour to its leaves. The stem, with a few exceptions, is always above ground, and is the perpendicular pillar from which various lesser growths, such as branches, shoot off laterally. "The stem," says Rennie, "is divided from the root by the part called the crown or collar. The space between the collar and the first leaf or bud is termed the bole; but the great body of a stem is called the trunk. The stem of grapes, corn, and reeds, is termed the straw; the stem of palms, ferns, mushrooms, and sea-weeds, is termed the stalk; the stem of such flowers as the primrose, the daisy, the snowdrop, and the lily, is termed the scape, though flower-stalk is certainly better; the running stem, as in the strawberry and cinquefoil, is termed a runner; a shorter runner that does not root, as in the house-leek, is termed an offset; a longer one that does not root, as in the cucumber, a vinelet; and a small stem proceeding laterally from a root or stool, a sucker."

The stem, it will be observed, assumes many forms and characters as to bulk, structure, position, place, and duration. It appears as a tuber (*Gladiolus*, 1), a bulb (the onion, 2), a scape (*Dodecatheon*, 3), a culm (*Arundo*, 4), or as a woody column (the oak, 5). It varies in size from that of a bristle to a trunk of many feet in diameter.

When a trunk bears permanent or perennial branches, the plant is termed a tree; when permanent branches arise, not from a trunk, but from the root, the plant is termed a shrub; when small and much branched, a copse shrub; when furnished with woody branches that are not permanent, as in the tree mignonette, it is termed an under-shrub; and when the whole stem is not woody, and dies down every year, at least as far as the crown of the root, the plant is termed an herb; when a trunk is formed like the underground stem of the iris, of the hardened bases of leaves which have withered and fallen, and is not taper, but all of one thickness, giving off no branches, as in the date and cocoa, the plant is termed a palm.

Buds, which have various forms, but are generally oval or roundish, consist of the young shoots either of leaf, flower, or twig, and proceed from what is called the axil of a leaf. They are usually formed either early in summer or in autumn, and are so contrived as to preserve from injury the delicate foliated structure within. The outside is composed of tough scales, which are frequently covered with a gummy resin, and they are internally kept warm by a downy substance interposed between the leaves. Buds are in most respects like bulbs, the scales being composed of cellular tissue, with distinct fasciculi running through it. This separation of the vascular fasciculi is the feature which distinguishes these scales from leaves. The inner scales perform the functions of leaves, until these are perfected and fully expanded, when they drop off; but in some trees, as in the apple and the almond, they are converted into leaves; whilst in others, as the rose, they are converted into the pellicles or foot-stalks of the real leaves, which spring out of them. When the central part of a bud contains leaves only, it lengthens upwards as it ex-

pands into a branch; thus a leaf-bud and a branch-bud may be said to be the same. When it contains a flower, this is situated as in the bulb of the tulip, in which small bulbs are formed on the edges of the crown of the root between the scales, which gradually enlarge at the expense of the scales, are detached, become perfect bulbs, and send up leaves and flower-stalks. With respect to the manner in which the leaves are folded—they may be plaited, as in the palm and birch; doubled, as in the rose and oak; embracing, as in the iris and the sage; double embracing, as in valerian, teasel, &c.; double compound, as in carrot, mimosa, &c.; rolled inwards, as in grasses; tiled, as in privet, lilac, &c.; rolled outwards, as in rosemary, primrose, &c.; rolled lengthways, breadthways, rolled from the tip to the base, or wrapped round the stalk.

The buds of trees, being in a state of great sensibility, and feeling the first warmth of the sun, the vitality of the continued shoot is roused into action; it attracts the moisture contained in the neighbouring cells charged with nourishing matter; the rising sap also enters its vessels; it gradually swells, and bursting the enclosing scales, pushes into the light and air, unfolding its leaves successively as it advances, until the whole tree becomes green.

Leaves.—Leaves are the grand ornament of plants, and from their numbers, position, and delicacy of organisation, they are designed to effect an important office in the vegetable economy. Springing from the branches, and exposed in profusion to the atmosphere, they perform the functions of a breathing apparatus analogous to that of the lungs or gills of animals. A similar purpose, at least, is designed, for the circulatory sap of plants, like the blood of animals, requires to be exposed to the atmospheric influence, in order that it may be suitable for nutrition. This purpose is accomplished by the agency of the leaves, to which the sap, on rising from the roots through the stem and branches, is propelled or attracted, and there both air and light exercise their beneficial influences. Gaseous qualities, however, are emitted as well as inhaled by the leaves; and that they allow the escape of aqueous fluids is well known. Leaves are thus indispensable to the growth of plants, and care should be taken not to injure them; for defoliation, either naturally or by art or accident, instantly arrests the growth, and the failure or diminished expansion of foliage is a certain sign of debility.

A leaf consists generally of two parts, the petiole, or leaf-stalk; and the lamina, or that part which is broad and thin. Sometimes, however, as in the rose tribe, stipules are attached to the base of the petiole. The leaf-stalk is that part which connects the leaf with the branch, and at the base will be found slightly hollowed, in which a bud rests. Sometimes the leaf-stalk is wanting, as in the sow-thistle and catch-fly, and in this case the leaf is said to be sessile or sitting. The lamina, or broad part of the leaf, is frequently of a different colour on the under side to what it is on the upper. This is exemplified in the common silver-weed (*Potentilla anserina*), the leaves of which are hoary on the lower side and green on the upper. Leaves are either *caducous*, falling in summer; *deciduous*, falling in autumn; *persistent*, remaining till pushed off in the following spring; or *perennial*, when of still longer duration, as in evergreens.

Some leaves are of a very remarkable shape, which none of the foregoing characters can describe. The most remarkable of these is the pitcher plant (*Nepenthes distillatoria*), which is seen in the annexed cut. The leaves of this plant are sheathing at the base, and at the end of the proper leaf is a petiole or stalk, several inches long, which is terminated by a bladder-like vessel, furnished with a lid. This vessel is always filled with water, which appears to be distilled from the plant itself.

With regard to the manner in which leaves project from the branches, and their distribution over the woody cylinder to which they are attached, every pos-

sible variety may be observed. They may be opposite, that is, two leaves growing on either side of the branch, the one directly opposite to the other; alternate, when one leaf springs out on one side of the branch, and another on the opposite side a little above it, and so on; whorled or *verticillate*, when a number of leaves grow round the stem from a common knot or joint, as in the bed straw. The distribution of alternate and opposite, however, is not regular; for in some instances it will be found that the leaves on the lower part of the stem are alternate, whilst those on the upper part are opposite.

The leaves of most plants possess a power of motion, which is the effect of what is termed irritability or vitality. Thus the leaves of the aspen (*Populus tremula*), from a peculiar formation of the petiole, never rest; and those of the sensitive plant (*Mimosa pudica*) close themselves up on the slightest touch. The flowers of many plants also possess this irritability, closing when night approaches. There is a numerous description of plants which have few or no leaves, as the torch and melon thistles; but their stems are much dilated, presenting a large superficies of parenchymous exterior to the air and light; or they are profusely covered with spines, which no doubt, conjointly, do the office of leaves. It may be remarked, that such plants as the common garden rhubarb, which require much moisture, are provided with very broad leaves, which catch the rain that falls upon them, and also, by their umbrageous quality, preserve the ground round the stalks from being parched by drought.

Green is the most general colour of leaves, but some are red, or purple, or yellow; some appear nearly white, in consequence of being clothed with short woolly or silky hair. They differ much in substance and structure; some are immensely thick and fleshy, as those of the genus *aloe*, others remarkably thin, as those of the beech. The texture of the surface is also very dissimilar; some are rough, prickly, and wrinkled, others smooth and glossy. Whatever be their form or appearance, it is found, by minute microscopic observation, that the interior of the fine membranous substance consists of cells and passages suitable to the due exposure of the sap, the inhaling of air, and the absorption of humidity from the atmosphere. The fine downy hair which grows on the leaves is understood to be of service in collecting dew at night, and supplying it to the plant.

Glands.—It is doubtful whether the bodies which usually receive this appellation (*glandule*) really exist in the vegetable system. There are, however, minute organs, differing in structure from the common texture of the part where they are situated, which separate some peculiar matter from the ordinary proper juice, and which may be regarded as glands. If this be admitted, these glands occupy the interior and exterior of stems and leaves, vary greatly in form and attachment, and perhaps in structure, although any attempt to demonstrate this can scarcely be depended upon. Internal vegetable glands are generally seated in the substance of leaves, with a small excretory duct or channel opening upon the surface of the leaf. These furnish the little drops of essential oil found on many leaves, as, for instance, that of the black currant. In some leaves, when the cells are swelled with fluids, these ducts are pressed upon and closed, so that the leaf exhales no odour, although a powerful odour is exhaled as soon as the withering of the leaf opens the ducts. This is the case in sweet-scented meadow-grass, whence new hay

derives its odour. External vegetable glands are either with or without a foot-stalk; and all these glands are cellular, with the cells more regular than those in the substance of the leaf, and arranged in circles: a cord of vessels can generally be traced into the substance of the gland. Bristles are sometimes the excretory ducts of glands, as exemplified in borage, the nettle, &c.

Flowers.—A flower consists of several distinct parts, the calyx, corolla, stamens, disk, nectarium, pistillum, and receptacle. A flower is essentially constituted by the presence of sexual organs, either male or female. When there is only one of these present, the plant is termed unisexual; but more commonly these organs are both present in the same flower, which is in this case termed a hermaphrodite. In some instances, although the same plant bears both male and female organs, it is not hermaphrodite, as these organs occur in different flowers; in others, again, the male and female flowers exist only in different plants. Lastly, male, female, and hermaphrodite flowers are sometimes found mingled together, either on the same or on different foot-stalks. Sometimes the male or female organs alone, protected in a small scale, constitute the flower; but in general they are surrounded and protected by the corolla and calyx. All these are commonly borne on a stalk called the peduncle (from *pedo*, to prop or support), which, expanding at its extremity, forms the receptacle or torus, as it has been called, upon which the whole of the parts above-mentioned are supported. What is called the berry in strawberries, appears to be nothing more than the receptacle bearing the naked seeds on its surface. It is called common when a number of florets rest on one receptacle. The round button which is exposed when the downy seeds are blown from the head of the dandelion, is an instance of the common receptacle.

The *calyx* is the external leafy envelope surrounding the flower, and in which it rests as in a cup. Sometimes it is entire, but more frequently it is divided into segments (*sepals*), which are more or less separated from each other. It is most commonly green, but in some flowers it is highly coloured.

The *corolla* is the true flower or blossom, and consists of several divisions or leafy parts, called *petals*, which are almost all articulated at the base, and consequently fall off at the earliest manifestations of maturity or decay. The extensive variety of tints in the flowering part of plants, is a remarkable circumstance in vegetable economy; and what may be the precise use of such gaiety of colour, has formed the subject of philosophic inquiry. Independently of the exceeding beauty to the eye, which is certainly a matter for pleasing gratulation, it is believed that the lively colours are useful in attracting insects, these creatures incidentally performing an office in the reproductive economy, and in carrying off saccharine exudations.

The lower part of the single petal of a corolla is called the claw, corresponding to the stalk of the leaf; and the broad part is called the limb. The corolla is frequently furnished with certain appendages, attached either to the throat or to the base of the petals, called nectaries. These are placed in different parts of the corolla; in the common auricle they surround the edge of the throat; in the ranunculus or buttercup tribe, they appear like scales at the bottom of the claw; and in the monkshood, in the form of a spur behind the corolla. They receive the name of nectaries from the supposition that they secrete honey, and they are always found to contain a clear, sweet-tasted fluid.

Stamens, &c.—Within the beautiful corolla are observed several small filamentous objects, on some of which are particles of fine coloured matter like dust. These are parts of the reproductive organisation, and consist of stamens and pistils. In general, a stamen consists of two parts, in most cases of a filament (from *filam*, a thread), which is usually white, and always of an anther, which is usually yellow or purple. It has been shown that the stamens are always next to the petals, that is, between their base and the base of the

seed-organ. It is upon the number and arrangement of the stamens that systematic botanical arrangements have principally been founded. The following are a few characteristics of the number, length, position, direction, &c., of the stamens. The number of stamens in each flower varies from one to twenty, or more. In length, they are equal or unequal, and this disproportion is sometimes symmetrical, sometimes not. In position they may be opposed to the divisions of the petals, or they may alternate with them. Sometimes they protrude beyond the corolla, at other times they are wholly included within it. Their direction may be erect, pendant, or horizontal, and their summit is variously inclined to or reflected from the centre of the flower. The filament which supports the anther is most commonly straight and filiform; sometimes, however, it is otherwise. It varies, from being as small as a hair to be large and flat like a petal, and its summit is either pointed or obtuse. On the summit is that essential part the *anther*, which is generally formed of two small membranous sacs, attached immediately to each other, or united by an intermediate connecting body. In form, anthers are subject to great variety, and, like the filaments, they sometimes cohere so as to form a sort of tube. Their colour is often yellow, orange, violet, white, &c., but never green or truly blue.

The pollen contained in the anthers consists of nume-

rous regularly-figured small particles, which possess in different plants a very different figure, size, and colour. The number of particles in a cell, which is very small, sometimes amounts to many thousands. In some flowers the pollen consists of transparent grains; in others they are of a white, purple, blue, or brown, and more frequently of a yellow colour. When a grain of pollen is dropped into water, it swells and bursts, and a minute quantity of matter escapes, which is supposed to be the fecundating principle of the pollen.

We may illustrate the action of the pollen from the anthers, by referring to the annexed small engraving. *a* is the filament or stalk of the stamen, *b* is the anther on its summit, and *c* is the pollen or dust in the act of being shaken down upon the stigma or upper part of a pistil, of which we observe three in a group.

In this figure, it may be remarked, that the anther is a roundish-shaped body, delicately poised on the filament, and ready to vibrate and shake its dust on objects beneath or near it.

In the larger engraving, figs. 9 and 10, the different parts of the flowering structure are combined, as they are frequently seen in nature.

Fig. 10.

f Peduncle.
g Calyx. *h* Corolla.

The pistil is a kind of tube with a communication from the stigma, through its style or stalk to the ovary or seed-bag beneath, and down this the pollen is permitted to exercise its influence. The seed-organ or ovary occupies almost always the inferior part of the pistil, and it is there that the process of fructification is fully effected. When cut open, it exhibits one or more cavities or cells, in which are contained the rudiments of the seeds or ovula; and it is in it that the change of the ovula into perfect seeds is effected. It is of various forms, but most commonly ovoidal. It is generally seated upon the receptacle together with the stamens, but frequently it is placed below the flower. Its cavity consists of one or more cells, in which the ovula or rudimentary seeds are found. It may be remarked, that the pistils spring from a nectary or disc in the centre of the flower, and surrounded by the stamens.

The precise mode of fructification is nowhere clearly stated. The stigmata are in all cases moistened with a clammy fluid, which causes the grains of pollen to swell, burst, and discharge their minute granules. Some suppose that these are taken up by spongelets in the summit similar to those of the root, while others allege that the fluid matter in which the granules float is sucked up. It has been discovered that the grains of pollen, when shed on the summit, in a few hours shoot out one or more delicate tubes, which by some philosophers are supposed to extend down as far as the seed-organs, and to expand around and between the nascent seeds. Some believe them to convey thither the granules, which at least enter into the tubes; others, however, deny that this is the case. The seed-organ lies at the base of the

pistil, and contains the seeds either nascent or advanced to maturity. It bears a very strong resemblance to the egg-organ of birds and insects, and its parts have accordingly received from naturalists the same scientific names. The seed-organ is usually of an egg-oblong form, and is always composed of an outer membrane, a middle membrane, and an inner membrane, all intimately united. As every seed derives its nourishment from the inner membrane, there must be a communicating point; and this point being always on the verge of the membrane, may be so termed; that on the seed being termed the seed-scar, but popularly, though improperly, named the eye. In some species the verge bears a number of smaller verges, to each of which a seed is attached, by means of the verge-cord or seed-stalk. All these parts are obvious in an unripe pea or bean.

Seed-vessels are various in form; as, for example, in the case of the pea, fig. 11, the vessel is a shell or pod, and in the case of the apple, fig. 12, it is the body of the fruit.

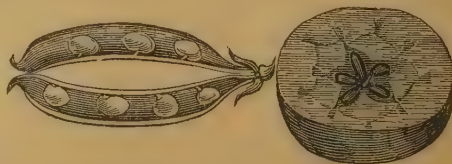

Fig. 11.

Fig. 12.

All fruits, in reality, are but so many vessels or recep-

tacles for the seeds, and the various forms in which they appear are individually suitable to the purposes of their growth.

Structural arrangements.—Vegetable, like animal structures, are composed of solid and fluid parts. Few of the latter are considered simple in their composition, as they contain more or less of a gelatinous matter, which frequently imparts to them a consistency approaching to that of a solid body. The gum which we often see exuding from trees, is an instance of the viscosity of vegetable fluids. Many of them, also, contain minute globules of matter, which thicken them to a considerable degree. It has next been discovered that these often cohere and form solid masses, or unite in lines so as to constitute fibres. These, again, collect together, and compose various kinds of texture. The solid parts of a vegetable are membrane and fibre, which form the tissues referred to, and their varied combinations in the bark, wood, pith, and medullary or marrow rays. The fluid elements are watery solutions of the soluble materials of the soil, which, by chemical and mechanical agency, as well as the influence of the principle of life, are decomposed, and again united in different proportions, so as to form new substances, or, in other words, the solid components, the textures, and secretions of the vegetable.

The elementary parts of the vegetable structure appear to consist of minute bags, bladders, or vesicles, the coats of which are transparent membranes of extreme tenuity. If a very thin slice of the stem of any plant be put into a drop of pure water, and examined by the microscope, it will be found to consist chiefly of these cells. Their size differs very considerably, from even the thousandth part of an inch to the thirtieth. Although in their original state they possess an oval or globular form, yet, by being variously compressed, they are made to assume other forms, such as twelve-sided figures, or six-sided, like a honey-comb, and pass by insensible gradations into the tubular structure. These various modifications of the same elementary texture have received separate technical names, which, however, it is unnecessary to specify. By the concurring observations of modern botanists, these cells consist of separate vesicles closed on all sides, and destitute of inlet or pore. It seems to have been satisfactorily established, that the partitions which separate them, however thin, must consist of a double membrane, formed by the adhesion of the coats of the two contiguous vessels, and that the fluids gain access not by means of regular apertures, for none can be detected, but by exuding through the substance of the membrane. As from the shape of the cells the coats cannot be supposed to unite at every point, the spaces thus formed have been called *intercellular passages, canals, &c.*, and they are supposed to perform an important part in the function of nutrition. The nature of the matter contained in the cells and the intercellular spaces, differs according to the part in which it exists, and the peculiar powers of the plant. Sometimes they are filled with certain liquids, the products of vegetable secretion; at other times the contents are simple watery sap, and occasionally they are only filled with air. Air-tubes and cells are most frequently met with in the centre of stems and in leaves, rarely in roots, and never in the woody part of plants. Although some plants consist entirely of cells, yet, as already observed, the greater number of them have, in addition to these, numerous ducts or vessels, consisting of membranous tubes of considerable length, interspersed throughout every part of the system. With regard to the origin of these, Dr Roget observes: "There can be little doubt, indeed, that the vessels of plants take their origin from vesicles, which become elongated by the progress of development in one particular direction; and it is easy to conceive, that, where the extremities of these elongated cells meet, the partitions which separate their cavities may become obliterated at the points of junction, so as to unite them into one continuous tube with an uninterrupted interior passage. This view of the formation of the vessels of

plants is confirmed by the gradation that may be traced among these various kinds of structures. Elongated cells are often met with applied to each other endwise, as if preparatory to their coalescence into tubes. Sometimes the tapering ends of fusiform cells are joined laterally, so that the partitions which divide their cavities are oblique. At other times their ends are broader, and admit of their more direct application to each other in the same line, being separated only by membranes passing transversely; in which case they present, under the microscope, the appearance of a necklace of beads. When, by the destruction of these partitions, their cavities become continuous, the tubes they form exhibit a series of contractions at certain intervals, marking their origin from separate cells. In this state they have received the names of *moniliform, jointed, or beaded vessels*. Traces of the membranous partitions sometimes remain where their obliteration has been only partial, leaving transverse fibres. The conical terminations occasionally observable in the vessels of plants also indicate their cellular origin."

Those parts of plants which do not exhibit the form of either membranes or cells, are comprehended in what is called the *vascular system*, which constitutes almost the entire bulk of the more solid parts of trees. If a branch be cut transversely early in spring, the sap will be found to exude, and cover the whole of the cut surface, which, if examined, will be found to consist of a vast number of exceedingly small fibres, vessels, or pipes, through which the liquid portions of the vegetable ascend or descend. These are, as it were, the veins and arteries of the plant. Indeed, whilst the tissue of cells above described may be said to constitute the flesh of plants, the tissue of fibres may be said to stand for the bones and other firm parts of the system. In animals, the fluids are conveyed to and from a central reservoir called the heart; but such an organ does not exist in the vegetable kingdom. The fluids enter by innumerable mouths at the root, and are conveyed by the vascular system to all parts of the plant fitted to receive them. There is little variation in the diameter of the vessels, and their general form is cylindrical. Their minuteness is quite astonishing. In a piece of oak of about the size of 1-19th of an inch, 20,000 vessels have been reckoned to exist. Hedwig measured the largest vessel in the stem of a gourd; it appeared 1-12th of an inch in diameter through his instrument, which magnified 290 times; so that its real diameter was the 3480th part of an inch. The vessels of plants do not, like those of animals, exist single, but are collected in bundles, or fasciculi as they are called, which sometimes contain hundreds of vessels. They occasionally also ramify; that is, some vessels shoot off from one parcel to unite with another, and afterwards return to that which they had left. By this ramification a reticulated appearance is frequently produced, especially in the bark and leaves of plants. They do not ramify like the vessels of animals from greater into less; but, by the division of a greater fasciculus into several smaller fasciculi, they at last become single, and thus their ramification is effected. It is generally supposed that they do not open into one another; that is, actually unite and be lost in each other, forming that kind of connexion which anatomists call *inoculation* or *anastomosing* (from a Greek word which signifies to open the mouth).

These vessels have been named according to the functions which they perform, or the appearances which they assume. There appear to have been two kinds of vessels discovered in plants, the straight and the spiral. Grew describes the former as straight hollow threadlets, fifty times finer than a horse hair, forming a larger tube, as if we should suppose a walking-cane composed of small straws. Leuwenhoeck describes them as composed, like the quills of birds, of two transparent tissues, one placed lengthways and the other across, with no lateral communication. It is the opinion of the highest authorities that both fibres and straight vessels take their origin from spiral vessels. The first is called the simple spiral. If the fleshy scale of any bulb, for in-

stance, that of the lily, be cautiously broken, and the parts separated, the spiral vessels will be observed like screws, partially unrolled. They consist of opaque silvery shining fibres, twisted in a spiral manner, so as to form a hollow cylinder, the spires being generally in contact. This hollow tube is sometimes formed of one continuous fibre, sometimes of several parallel fibres adhering together. The fibres are tenacious, and in some plants elastic. They differ much in size in different plants, and at different stages of the growth of the same plant. They stretch through the whole of its length, from the roots to the leaves and flowers, following the various curvatures of the stem. Grew found that they alternate with the straight vessels in every part of the wood, and surround and ensheath them in the leaf-stalk, the leaf, the flower, and the fruit. The straight vessels are said to be formed in spring, the spiral vessels in summer. These spiral vessels undergo various transformations. In many cases the inner fibres of the tube, instead of forming a continuous spiral, appear in the shape of rings succeeding one another at regular intervals, and constituting what are called annular vessels (from *annus*, a ring). This is considered a primary form of vessel, and from the two simple varieties of vessels described, more complex forms are elaborated as the plant advances in age. In the punctuated vessel the spires are separated to nearly equal distances from each other, and the intervening spaces are filled up with a membrane sprinkled over with small obscure points or dots.

This is the largest with respect to the diameter of the vegetable vessels; it is at first transparent, but becomes opaque by age. A fourth variety of vessel, which has the same origin as the last, being formed of rings, is that in which the separations are not filled with membrane, but with small productions proceeding from these rings themselves. These ramifications often have the appearance of network, whence they derive the name of *reticulated* spiral vessels. It is impossible, in the present limited treatise, to go into a definition of the varieties and purposes of these vessels; and it will suffice to say that the spiral vessels, in all their variety, serve the office of conveying the sap throughout the whole of the plant. Besides the vessels already enumerated, vegetables contain certain organs denominated *glands*, which are composed of closely-compacted cells, and which perform the function of *secretion*; that is, the conversion of the nutritious juices into particular products required for various purposes in the economy of the plant.

Among the parts associated with or arising from the elementary structure already mentioned, are the pith, the wood, the bark, and the epidermis or skin. The pith is that soft, light, and spongy sort of substance which occupies the centre of the stem (hence sometimes called the heart), where it is commonly surrounded by a circle of vessels, which construct for it an appropriate canal. When seen in its most perfect form, it is found to consist entirely of cellular tissue, rather loose in texture, as in the alder, or compact, as at the knot of the ash. The wood (*lignum*) is that hard cylinder which immediately surrounds and envelopes the pith, and is enclosed by the bark. It is essentially composed of vessels, and of cellular tissue combined in an infinite variety of ways, and exhibiting every diversity of form. If a tree of several years' standing be cut transversely and examined, it will be found to consist of a number of cylinders, enclosing one another like so many layers or concentric circles disposed around an axis. By the number of these the age of the tree may be determined.

Fig. 13. is a section of a stem five years old, having the pith in the centre, and a cylindrical layer

Fig. 13.

for every year of the growth, and the bark on the outside. The outermost layer, which is spongy and less durable than the inner or heartwood, is called alburnum. The whole are traversed by rays or lines diverging from the centre of the stem to its circumference. These are called medullary rays, or silver grain, and they are composed chiefly of large cells, extending transversely, or in the direction of the diameter of the tree, and composing by their union continuous vertical planes the whole length of the trunk. They are called medullary (from *medulla*, marrow), because they were supposed to be processes of the pith, or a continuation of it, which is not the case. Their use appears to be to keep open the communication between the bark and the pith, which the formation of the wood would otherwise have destroyed. The bark resembles wood in its component parts, being made up like it of vessels and cellular tissue, intimately connected with each other. As in trees a new layer of vessels is annually added to the wood, so a similar but much thinner layer is also made to the bark, to which the name of *liber*, or inner bark, is usually applied, the old layer being pushed outwards. Between the vessels thus annually produced, a considerable portion of cellular tissue is interposed, the cells being commonly filled with juices. The whole is surrounded by an outer zone or envelope, to which the name of skin, epidermis, cuticle, or rind, has been given. It is an extremely thin membrane, and extends over the surface of every part of the plant, excepting the spongelets of the roots, and the summit of the pistil in flowers. The rind of plants is similar to the skin of animals in the functions in which it performs. It is, no doubt, intended to protect the more sensible organs beneath. As the scarf-skin of the hand becomes indurated by hard labour, so the rind of the tree, if exposed to a stormy climate, becomes rough, whilst the rind of the same species of plant, if reared in a sheltered situation, like the hands of a delicate lady, remains smooth. As the plants grow, the rind stretches, and sometimes to a considerable extent; but in cases in which it is not easily stretched, as in the elm, it breaks up into innumerable cracks. The birch, and some other trees, "cast their bright skin yearly, like the snake." The rind is transparent and colourless where it is very thin; but it is usually of a brown or grey colour when thick. Various opinions are entertained respecting the origin and structure of this membrane. Some philosophers hold it to be continuous with the bark, and formed of the outer sides of its cells. Others describe it as a separate membrane, composed of minute cells, or "bladders," as Grew calls them, which shrink and are dried up as the plant grows older. This opinion is now supported by the highest authorities. There has in some instances been found a very delicate, transparent, and apparently inorganised, membrane on the outside of the rind. Whether it possessed pores, or, as they are sometimes termed, glands, was long a disputed point, but their existence has lately been incontestably proved. They are a sort of minute bags opening on the outside by an oval slit with a raised border, which contract when water or moisture is applied, and expand in dry air, or when exposed to sunlight.

Having already defined what constitutes the chemical elements of plants, as well as the nature of the food which they derive from the atmosphere and soil, nothing more need here be said on the subject, and we pass on to a short account of the methods by which the ascent and descent of the sap are effected.

The various matters held in solution by the fluid enter the plant in a perfectly crude state. The liquid rises in the stem of the plant, undergoing little or no perceptible change in its progress, and is in this state conducted to the leaves, where it experiences various important modifications. By causing the roots to imbibe coloured liquids, the general course of the sap has been traced with tolerable accuracy, and it is found to traverse principally the ligneous substance of the stem; in trees, its passage is principally through the albur-

num; that is, the wood last formed, and not through the bark, as was at one time believed.

The course of the sap varies under different circumstances, and at different periods of vegetation. At the time when young buds are preparing for their development, which usually takes place after the genial warmth of spring has penetrated beyond the surface of the earth, and expanded the fibres and vessels of the plant, there is created an urgent demand for nourishment, which the roots are actively employed in supplying. As the leaves are not yet completed, the sap is at first applied to purposes somewhat different from those it is destined to fulfil at a more advanced period, when it has to nourish the fully expanded organs; this fluid has, accordingly, been called the nursing sap. It does not rise through the alburnum, but through the wood which is immediately contiguous to the pith, and thence passes, by unknown channels through the other layers of wood, to the buds, which it nourishes. In this circuitous circulation it is supposed to undergo a change, or becomes assimilated, in which state it is fitted for entering into combination with the plant, or becoming incorporated with the new organisation. This nursing sap has been compared to the milk of animals, which is prepared for a similar purpose at those times only when nutriment is required for the rearing of their young.

The nutrient sap, which, as we have seen, rises in the stem, and is transmitted to the leaves without any change in its qualities or composition, is immediately, by the medium of the stomata, or orifices which abound in the surface of those organs, subjected to the process of exhalation. The proportion of water which the sap loses by exhalation in the leaves, is generally about two-thirds of the whole quantity received; so that it is only the remaining third that returns to nourish the organs of the plant. It has been ascertained that the water thus evaporated is perfectly pure, or at least does not contain more than a 10,000,000th part of the foreign matter with which it was impregnated when first absorbed by the roots. The water thus exhaled, being dissolved by the air the moment it escapes, passes off in the form of invisible vapour. Hales made an experiment with a sun-flower, three feet high, enclosed in a vessel, which he kept for fifteen days, and inferred from it that the daily loss of the plant by exhalation was twenty ounces; and this, he computes, is a quantity seventeen times greater than that lost by insensible perspiration from an equal portion of the surface of the human body.

The comparative quantities of fluid exhaled by the same plant at different times are regulated, not so much by temperature, as by the intensity of the light to which the leaves are exposed. It is only during the day, therefore, that this function is in activity. De Candolle has found that the artificial light of lamps produces on the leaves an effect similar to that of the solar rays, and in a degree proportionate to its intensity. As it is only through the stomata that exhalation proceeds, the number of these pores in a given surface must considerably influence the quantity of fluid exhaled.

By the loss of so large a portion of the water, which in the rising sap had held in solution various foreign materials, these substances are rendered more disposed to separate from the fluid, and to become consolidated on the sides of the cells or vessels, to which they are conducted from the leaves. This, then, is the first modification in the qualities of the sap which it undergoes in those organs.

The sap having undergone in the leaves the double processes of exhalation and aëration, is thereby elaborated into a fluid corresponding to the blood of animals, and fitted for becoming incorporated with the vegetable organs. The crude fluid which enters the leaves is

Cellular Membrane expanding perpendicularly.

called the ascending sap; and after it leaves them, in order to be distributed throughout the plant, it has been called the returning sap. It still contains a considerable quantity of water, but a large proportion of that which has not been exhaled by the leaves, and its elements, oxygen and hydrogen, has combined with certain other substances, so as to form proximate vegetable products, of which gum is the simplest, and generally the most abundant. The returning sap descends from the leaves through two different structures. In exogenous plants, the greater portion finds a ready passage through the liber, or innermost layer of bark, and another portion descends through the alburnum, or outermost layer of the wood. With regard to the exact channels through which it passes, the same degree of uncertainty prevails as with regard to those which transmit the ascending sap. De Candolle maintains, that in either case the fluids find their way through the intercellular spaces; other physiologists, however, are of opinion that particular vessels are appropriated to the office of transmitting the descending sap. The nature of the forces which actuate the sap in its descent from the leaves, and its distribution to different parts, as well as those powers which contribute to its motion from the roots to the leaves, are involved in equal obscurity. The hypothesis that it resulted from capillary attraction, is now generally abandoned.

SECRETION AND EXCRETION IN VEGETABLES.

The modifications which the returning sap undergoes, and its conversion into gummy, saccharine, amylaceous, or ligneous products, are effected by the simpler kinds of cells. But there are other cellular organs in which greater changes take place in its nature, the agents for effecting which are unknown, and are therefore referred generally to the vital energies of vegetation. The process is termed secretion, and the organs by which it is conducted, glands. The matter secreted is sometimes retained in the cells, and sometimes appears on the outside as an excretion, for the plant has the power of throwing out by the root those superfluous or noxious matters which, if retained, would injure it. This explains the fact why plants render the soil where they have long been cultivated less suitable to their continuance in a vigorous condition than it originally was; and also why plants of a different species are frequently found to flourish very well in the same situation, where this apparent deterioration of the soil has taken place.

The vessels in which the fluid secretions are contained are of a peculiar kind, and exhibit ramifications and junctions resembling those of the blood-vessels of animals. We may also discover, by the aid of the microscope, that the fluids contained in these vessels are moving in currents with considerable rapidity, as appears from the visible motions of their globules; and they present, therefore, a remarkable analogy with the circulation of the blood in some of the inferior tribes of animals. This curious phenomenon was first observed by Schultz in the chilionium, in the year 1820; and he designated it by the term *cyclosis*, in order to distinguish it from a real circulation, if, on further inquiry, it should be found entitled to the latter appellation.

The circular movements which have been thus observed in the milky juices of plants, have lately attracted much attention among botanists; but considerable doubt still prevails whether these appearances afford sufficient evidence of the existence of a general circulation of nutrient juices in the vegetable systems of those plants which exhibit them; for it would appear that in reality the observed motions of the fluid are in every case partial, and the extent of the circuit very limited. The cause of these motions is not yet known; but probably they are ultimately referable to a vital contraction of the vessels, for they cease the moment that the plant has received an injury, and are more active in proportion as the temperature of the atmosphere is higher.

BOTANY.

Various eminent individuals have attempted the classification and naming of plants, each of whose arrangements is called a *system*, and possesses certain peculiar features. The three systems which have been most esteemed, and wholly or partly adopted, are those of Tournefort (1656—1708), Linnæus (1707—1778), and Jussieu (1699—1777).

THE SYSTEM OF TOURNEFORT.

Tournefort founded his system on the absence or presence, the figure, situation, and proportion, of the *corolla*. This part of the flower is always, when present, the most conspicuous and imposing, and attracted the notice of the earlier botanists, as it does that of children now, more than it really deserved; because, in fact, no part of the flower is more subject to incidental change than the corolla. He divided the vegetable kingdom into two principal parts, namely, herbs and trees; the primary divisions he subdivided into twenty-two classes, the first seventeen of which comprise the herbs, and the other five the ligneous vegetables; these are again separated into one hundred and nineteen sections, but without names or titles being applied to them, as in those of other botanists. The characters of these sections were not always sufficiently defined; and consequently the young botanist often met difficulties in arranging plants in their proper places.

Though now known to be imperfect, the system of Tournefort possesses great merit. His labours, considering the state of the science when he lived, were indeed great, and far surpassing those of either Linnæus or Jussieu. In fact, Tournefort was pioneer to both, and amassed, and in many cases assorted to their hands, the materials of which both their systems are formed.

THE LINNÆAN, OR SEXUAL SYSTEM.

The sexuality of plants had been discovered long before the time of Linnæus; but, as far as is now known, he was the first who suggested the idea of classifying plants according to the numbers, connexion, and stations of the male and female organs. From the moment the idea occurred to him, he was indefatigable in the completion of a system which, no doubt, he fondly flattered himself was founded in nature. His great acquirements as a scholar, his love of natural history, his station among learned men, and his connexion with many learned societies, eminently fitted him for achieving this great and laborious work.

The plan of the Linnæan system of botany was intended to comprehend the whole vegetable kingdom, which was arranged in two grand divisions, namely, plants having visible flowers (*Phanogamia*), and plants having no visible flowers (*Agamia* or *Cryptogamia*). The whole are included in twenty-four classes; and these classes are subdivided into orders, genera, and species. The terms used to express the classes are compounded of the Greek numerals and the word *andria*, signifying man. These classes are subdivided into orders, which are designated from their number of pistils by Greek numerals also, with the addition of the word *gynia*, which signifies woman. The following is a summary of the distinguishing traits of the respective classes:—

1. Monandria, with one stamen—Maretail.
2. Monandria, with two stamens—Speedwell.
3. Triandria, with three stamens—Grasses.
4. Tetrandria, with four stamens—Bed-straw.
5. Pentandria, with five stamens—Primrose.
6. Hexandria, with six stamens—Snowdrop.
7. Heptandria, with seven stamens—Water plantain.
8. Octandria, with eight stamens—Heath.
9. Enneandria, with nine stamens—Flowering-rush.
10. Decandria, with ten stamens—Pink.
11. Dodecandria, with eleven to nineteen stamens—Agrimony.
12. Icosandria, twenty or more, inserted into the calyx—Rose.

13. Polyandria, twenty or more, inserted into the receptacle—Poppy.
14. Didynamia, two long and two short—Foxglove.
15. Tetradyndamia, four long and two short—Wallflower.
16. Monadelphina, filaments combined in one set—Geranium.
17. Diadelphia, filaments united into two sets—Pea.
18. Polyadelphia, filaments united into more than two sets—St John's Wort.
19. Syngenesia, anthers united into a tube, flowers compound—Thistle.
20. Gynandria, stamens situated upon the style, above the germen—Orchis.
21. Monocia, stamens and pistils in different flowers on the same plant—Spurge.
22. Dioecia, stamens and pistils in separate flowers and on different plants—Willow.
23. Polygamia, stamens and pistils united or separate, on the same or on different plants, and having two different kinds of perianth—Orache.
25. Cryptogamia, stamens and pistils not visible—Moss.

A more minute analysis of the system is as follows:—

Flowers with stamens of a fixed number, and equal in length.

FIRST CLASS, or Monandria, having one stamen.—If they have one pistil, they are of the first order, or Monogynia; if two pistils, they are of the second order, or Digynia.

SECOND CLASS, or Diandria, having two stamens.—If they have one pistil, they are of the first order, or Monogynia; if they have two pistils, they are of the second order, or Digynia; and if three, they are of the third order, or Trigynia.

THIRD CLASS, or Triandria, having flowers with only three stamens.—If they have one pistil, they are of the first order; if two, they are of the second order, and if three, of the third order.

FOURTH CLASS, or Tetrandria, having flowers with only four stamens equal in length.—If they have one pistil, they are of the first order; if two, of the second; three, of the third; and if four, of the fourth order, or Tetragynia.

FIFTH CLASS, or Pentandria, having flowers with only five stamens.—Those having from one to four pistils are named as in the preceding classes; those having five pistils belong to the fifth order, or Pentagynia; and if they have many pistils, to the sixth order, or Polygynia.

SIXTH CLASS, or Hexandria, having flowers with six stamens.—As they have one, two, or three pistils, they belong to the first, second, or third orders; if they have six pistils, to the fourth order; and if many pistils, to the fifth order.

SEVENTH CLASS, or Heptandria, those having only seven stamens.—If they have one or two pistils, they are classed as before; if four pistils, they belong to the third order; and if seven pistils, to the fourth order.

EIGHTH CLASS, or Octandria, having flowers with only eight stamens.—If they have from one to four pistils, they rank in the order corresponding to the number.

NINTH CLASS, or Enneandria, those having only nine stamens.—If they have one pistil, they belong to the first order; if three, to the second; and if six, to the third.

TENTH CLASS, or Decandria, having only ten stamens.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth; and if ten, to the fifth order.

Flowers with stamens of rather uncertain number, but of fixed insertion.

ELEVENTH CLASS, or Dodecandria, having flowers with from eleven to nineteen stamens inserted into the receptacle.—If they have from one to five pistils, they belong to the orders corresponding to these numbers; and if they have about twelve pistils, they belong to the sixth order.

TWELFTH CLASS, or Icosandria, having flowers with twenty or more stamens inserted into the flower-cup or

the blossom.—If they have one, two, or three pistils, they belong to the first, second, or third orders; if five, to the fourth order; and if many pistils, to the fifth order.

THIRTEENTH CLASS, or Polyandria, those having flowers with from twenty to one hundred stamens inserted into the receptacle.—If they have from one to six pistils, they are classed as before; if they have many pistils, they belong to the seventh order.

Flowers with two of the stamens shorter.

FOURTEENTH CLASS, or Didynamia, having flowers with four stamens, two longer and two shorter, inserted on a one-petalled blossom.—If the four seeds appear not to be in a seed-vessel, they belong to the first order, or Gymnospermia; but if they appear to be concealed in a seed-organ, they belong to the second order, or Angiospermia.

FIFTEENTH CLASS, or Tetrastynamia, having flowers with six stamens, four longer and two shorter, the blossom with more petals than one.—If the seed-organ is a short pod, they belong to the first order, or Sili-culosa; and if a long round pod, to the second order, or Siliquosa.

Flowers with stamens united by their filaments.

SIXTEENTH CLASS, or Monadelphia, having flowers with the filaments of all the stamens united at the base into one bundle.—If there are three stamens, they belong to the first order, Triandria; if five stamens, to the second order, Pentandria; if seven stamens, to the third order, Heptandria; if eight stamens, to the fourth order, Octandria; if ten stamens, to the fifth order, Decandria; if eleven stamens, to the sixth order, Endecandria; if from twelve to twenty stamens, to the seventh order, Dodecandria; and if more than twenty stamens, to the eighth order, Polyandria.

SEVENTEENTH CLASS, or Diadelphia, having flowers with the filaments of all the stamens united into two bundles.—If they have five stamens, they belong to the first order, Pentandria; if six stamens, to the second order, Hexandria; if eight stamens, to the third order, Octandria; and if ten stamens, to the fourth order, Decandria.

EIGHTEENTH CLASS, or Polyadelphia, having flowers with the filaments of all the stamens united into three or more bundles.—If there are from twelve to twenty-five stamens unconnected with the flower-cup, they belong to the first order, Dodecandria; if the bundled stamens are inserted in the cup, to the second order, Icosandria; and if there are more than twenty-five stamens unconnected with the flower-cup, to the third order, Polyandria.

Flowers with stamens united by their anthers.

NINETEENTH CLASS, or Heptandria, having flowers composite, with all the anthers in a floret united into a tube, whilst their filaments are not united. If all the florets are equal, they belong to the first-order, Polygamia equalis; if the florets of the circumference have pistils without stamens, to the second order, Polygamia superflua; if the florets of the circumference have neither stamens nor pistils, to the third order, Polygamia frustranea; if the florets of the circumference have pistils without stamens, and those of the centre stamens without pistils, to the fourth order, Polygamia necessaria; and if the florets have a partial flower-cup all within a general flower-cup, to the fifth order, Polygamia segregata.

Flowers with the stamens and pistils united.

TWENTIETH CLASS, or Gynandria, having flowers with the stamens inserted upon the style or seed-organ. If they have one stamen, they belong to the first order, Monandria; if two stamens, to the second order, Dian-dria; if three stamens, to the third order, Triandria; if four stamens, to the fourth order, Tetrandria; if five stamens, to the fifth order, Pentandria; if six stamens, to the sixth order, Hexandria; and if eight stamens, to the eighth order, Octandria.

Flowers of only one sex.

TWENTY-FIRST CLASS, or Monoecia, having flowers, some with pistils only, and some with stamens only, on the same plant. There are nine orders, taken from the number and bundling of the stamens, as before.

TWENTY-SECOND CLASS, or Dioecia, having flowers with pistils only, or with stamens only, on two separate plants of the same species. There are nine orders, founded as in the preceding class.

TWENTY-THIRD CLASS, or Polygamia, having flowers with both stamens and pistils, and also with only one of these, both on the same and on separate plants of the same species. There are three orders.

No flowers apparent on the plants.

TWENTY-FOURTH CLASS, or Cryptogamia. Stamens and pistils, if present, cannot, from being very minute, be ascertained. The class contains five orders—Ferns, *Filices*; Mosses, *Musci*; Liverworts, *Hepaticæ*; Sea-weeds, *Algæ*; and Mushrooms, *Fungi*.

To these Linneus added another class, or rather appendix, which he called *Palma*, the flowers of which were not sufficiently known in his time to admit of their being properly placed in the system. They are now distributed into the various classes and orders of the sexual system; they are still kept separate by Jussieu, who has, as Linneus did, arranged them into an order by themselves, under the old name. In fact, the genus *Palma* is of all others the least associable with the Linnæan plan of arrangement; being as distinct a tribe of plants in their structure, forms, and manner of growth, as can be found in the whole vegetable kingdom. Still there were stations provided for them in the sexual scheme, where they have been placed by late writers; but, as already observed, they do not associate well with the genera among which they are ranked. For instance, who would imagine that the cabbage-palm (*areca oleracea*) and the Scotch pine (*pinus sylvestris*) were any way allied to each other? Yet the Linnæan botanist must unite them, because their flowers are respectively monoecious, and their stamens are united in one brotherhood.

THE JUSSIEUIAN, OR NATURAL SYSTEM.

The author of this new system of botany has taken a very comprehensive view of the vegetable kingdom, and has been fortunate in fixing on those greater characteristics of plants which distinguish them from each other, and which at the same time are the least variable. On examining closely the vegetable membrane, he found it was either uniformly simple, that is, consisting of tissues of cells of nearly equal size and consistence, or of tissues of which the cells were of various sizes intermixed with each other, and formed into fibres lying in straight or in spiral positions, and forming tubes and openings of different structure and consist-

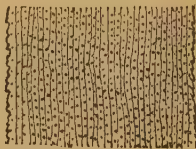

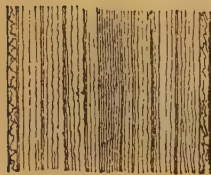

Germination of Dicotyledonous and Monocotyledonous Plants.

ence. This evident difference of structure served to divide the vegetable kingdom into two parts; the first he called *Cellulares* or *Acotyledoneæ*, that is, plants formed wholly of cellular membrane, and rising from their seeds, or spores, destitute of cotyledons or seed-leaves. Among these Acotyledoneæ are embraced the lower grades of the vegetable creation—the Filices, the Musci, the Hepaticæ, the Algæ, the Fungi—being placed, as it were, at the bottom of the scale, and exhibiting, in their outward aspect as well as in their internal structure, nothing of that loveliness of form,

and but rarely that brilliancy of colouring, by which some of the other divisions of plants are distinguished. They are the first and rudest types of vegetable life, many of them consisting merely of a cluster of minute cells, or of minute threads, as in the case of *proto-coccus* and *byssus*; and many of them being, in fact, nothing more than a mere slime or mucus, as in the *moulds* and *nostocs*. Yet these minute and apparently insignificant tribes of vegetables, as already stated, are by no means useless or superfluous in the scale of nature.

The plants composed of the second description of membrane, Jussieu named *Vasculares* or *Cotyledonæ*, because the organisation was more complicated, consisting of cells of various size, lying in various positions, in denser or looser laminae or partitions, and being invariably fibrous; and, moreover, rising from their seeds furnished with cotyledons or seed-leaves. Of these, some presented one seed-leaf only, but the great majority presented two; hence the latter were called *Dicotyledonæ*, and the former *Monocotyledonæ*. This difference in the development of the seedlings of *Vasculares*, served as a basis for the two classes into which it is divided and named, as above stated.

But besides the difference in the germination of vascular plants, they also differ materially in the manner of their growth. The first class, *Dicotyledonæ*, is annually increased in bulk by additions of bark and wood on the outside, hence it is also called *Exogenes*; whereas the second class, *Monocotyledonæ*, is enlarged by the expansion of the interior parts of the stem, and therefore is also called *Endogenes*. These are very striking cha-

Sections of Dicotyledonous and Monocotyledonous Stems.

acteristics of the two classes, as regards their manner of growth; but there is another very obvious distinction, not only in the structure of their stems, but in their leaves. In a leaf of the first class, the petiole, or footstalk, is extended directly through the web or face, and is branched pretty regularly from the mid-rib (*costa*) to the margin; whereas in a leaf of the second class, there is no very conspicuous costa or mid-rib, the petiole being pretty equally divided at the base of the

By these obvious distinctions in the manner of the germination of the seeds, the modes of accretion, and in the structure of the stems and foliage, the two classes of *Cotyledonæ*, or vascular plants, are clearly marked. But as there are great differences with respect to the stations, connexions, and numbers of the floral members of the plants included in this first division, the author of the system found it expedient, in order to facilitate the study of the science, to separate it, as already stated, into two classes; namely, *Dicotyledonæ* and *Monocotyledonæ*; the former being again separated into two subdivisions, namely, *Dichlamydeæ*, that is, plants whose flowers have two coats or coverings, the calyx and corolla being distinct; and *Monochlamydeæ*, that is, plants whose flowers have one coat or covering, the calyx and corolla not being distinct, but blended in one, as exemplified in those of the *mezereon*.

Monocotyledonous Leaf of the *Gloriosa Superba*.

In so limited a treatise it would be impossible, even were it desirable, to mention all the features and characteristics of the Jussieuan system, as comprehended in its ramified divisions, subdivisions, orders, genera, and species; and, indeed, to acquire any thing like useful knowledge on the subject, it must be studied practically in the garden and fields, under the instructions of a master. It is generally allowed that the minute complexity of the subdivisions and orders is most perplexing to the pupil, and a simplification in this respect, as well as in the harshness of the nomenclature, would be very desirable. It is well known that there are many genera which stand on the confines of two orders, with neither of which they exactly agree. In such cases, uniting the neutral with one or other of the more decidedly marked orders, would surely be better than constituting a new order, merely for the purpose of more completely or scientifically identifying one unsociable plant. It appears that Jussieu himself was strongly impressed with the desire of limiting the number of his orders, as well as the genera; nevertheless, almost all the improvements which have been recently made in the system by his followers, are divisions of orders, and subdivisions of genera, thus expanding rather than simplifying the system.

It cannot be denied, however, that there are many persons engaged in the cultivation of plants who would rejoice at seeing a new scheme of scientific botany by which the orders of the natural system would be reduced, and the number of genera diminished. Such a thing is not so impracticable as may be imagined; a master mind to contrive, and a few talented practical botanists to sanction the scheme, and fix the nomenclature, would be a work well worth the attention and labours of some universal botanical society instituted for this special purpose.

Botany, as well as every other science, has lately been greatly advanced by that friendly and highly commendable intercourse and interchange of social and scientific communion between home and foreign professors; and no doubt, whatever may be its defects, an union among its professors will speedily supply a remedy:

Dicotyledonous Leaf of the common Apple-tree.

leaf into several branches, which run in nearly parallel lines to the point.

NATURAL THEOLOGY.

NATURAL THEOLOGY is that branch of logical science which comprehends the discovery of the existence and attributes of a Creator, by investigating the evidences of design in the works of the creation; and, in an enlarged sense, it refers to the probable intentions of God with regard to his creatures, their duty, and conduct.

It cannot but appear to every rational mind, that a subject involving such important views and considerations is full of the deepest interest, and may be made the agent of much intellectual improvement. It is incumbent on us to read the wisdom of God, and his admirable contrivance, in all that we see around us and above us, and which pertains to the universe to which we belong. Independently of the pleasure, and perhaps worldly advantage, which the study of Natural Theology will produce, it will be equally serviceable in keeping alive feelings of piety and devotion. As Lord Brougham has properly remarked, "even the inspired penmen have constant recourse to the views which are derived from the contemplation of nature when they would exalt the Deity by a description of his attributes, or inculcate sentiments of devotion towards him. 'How excellent,' says the Psalmist, 'is thy name in all the earth! thou hast set thy glory above the heavens. I will consider the heavens, the work of thy fingers; the moon and stars which thou hast ordained.'"

It is worthy of remark, as showing the depth and solidity of the foundation on which rests the existence of a supreme, intelligent, and beneficent First Cause, that the farther we push our discoveries, the more clearly are the Divine perfections exhibited. It is not merely true that, on a superficial view, we perceive the necessity of believing that a limited and changing world, such as that on which we dwell, could neither exist without being produced, nor be the author of its own existence; and that there must, therefore, be, beyond the range of our senses, an independent and uncreated Essence, without beginning, without bounds, incapable of change, intelligent, ever-active, all-pervading; but it is also certain, that those views are not only uncontradicted, but fully established by the most minute survey of the objects within the sphere of our vision; so that he who penetrates the deepest into the secrets of nature, only multiplies proofs of that most sublime and most animating truth, that "verily there is a God" who made and rules the universe. It is difficult to understand that strange moral obtuseness which has induced a certain class of writers to reject this; for grant but one assertion, which is—and it is not easily to be questioned—that there exist in nature indisputable traces of design, planned with wisdom, directed by goodness, and accomplished by power, and it follows that there also of necessity must have been a *wise, a good, and a powerful Designer*.

Let us suppose ourselves cast ashore upon some island previously unknown to us; we immediately proceed to examine the appearances which present them-

selves, in order to discover if any traces exist of human inhabitants. To ascertain if such beings there existed, it would not be necessary that they should actually be seen by us. In our wanderings we might come upon a hut bearing all the marks of occupation; we might see the roots of the trees which had been felled to form it, and other tokens of the recent presence of man upon the spot; and did we desire to discover something of their character and habits before we presented ourselves to their notice, it is most probable that sufficient data would be also afforded on which to found an opinion. Were the habitations we discovered merely wigwags, or rude enclosures destitute of the conveniences of civilised life; or were the furniture, the weapons, or the instruments in and around them, such as barbarous nations generally use, we might reasonably argue that we had found the dwelling of an untamed savage. But if, instead of this, we find the surrounding land trenched, enclosed, and cultivated; should we find the common articles of European husbandry, and the common utensils of an European household, we should naturally draw the inference that we had reached the abode of an emigrant, who had thus reared around him the attributes of civilised life. Much more a few additional observations might reveal to us, and enable us to form conjectures, bearing the aspect of probability, concerning the people among whom we had fallen. Now, it is in this way alone that we can argue respecting the Author of all things, and discover proofs and demonstrations of a first supreme Cause. To prove that the formation of all things was the result of design, it is only necessary to show that they are in general, or in so far as we can discover, admirably suited to the uses and purposes to which they are to be applied—that their arrangement is perfectly harmonious—and that it is impossible that any chance could have thrown them together in a way so happy. To discover if this design can be evidenced or demonstrated, it is necessary to seek through the various works of creation with which we are surrounded; and the more minute we make our inspection, the more likely shall we be to perceive the deduction. If there be some departments to which our senses have a readier access than to others, and which we can therefore more readily examine, from these especially we ought to deduce our result. It may be that we shall find many things, which, from the deficiency of our observing faculties, we cannot understand, nor discover the uses or consequent design which they display; but still, if, in the course of our inspection, we find every part admirably adapted for a specific purpose, and teeming with the most convincing evidences of design, then we may with safety and true philosophy infer that in those objects, which from their nature and our imperfection we cannot so completely investigate, a greater degree of light would tend to confirm the result to which our previous observations, among other things, had led us.

DESIGN IN THE PLANETARY SYSTEM.

To the uninstructed eye, the earth which we inhabit appears on a clear night to be surrounded by a numerous host of radiant points, which, rising in the east, move majestically through the sky until they reach the western horizon, when they set or disappear; and so completely does this idea commend itself to the mind of an observer, that it requires a considerable effort to conceive how it can be otherwise. But science has taught us that this is a mere illusion, and the discoveries of Copernicus and Sir Isaac Newton have established the truth suggested by Pythagoras upwards of 2000 years before the time of either of them, that the apparent motion of the heavens is the consequence of the real revolution of the earth every twenty-four hours upon its axis; that, with relation to the earth, the sun is stationary, while the earth every year completes a journey round him; that the planets are globes similar to our own, revolving at once upon their own axis, and round the sun; that the moon is a satellite or attendant upon the earth, accompanying it in its course, and at the same time describing every month a circular orbit round it; and that to several of the planets are attached similar moons or satellites, bearing to them a corresponding relation.

By turning to our article ASTRONOMY, in which the number of the planets, and their distances from the sun, with other particulars, are noted, it will be seen that the earth which we inhabit is but a very small point, even in the solar system (as the concourse of planets round the sun has been called), and that it forms but a part of one magnificent and resplendent whole. But to ascertain the marks of a designing mind in this mighty maze of brilliant wonders, let us turn our attention to some of those particulars regarding them with which we are acquainted; and it must be confessed, that, if we are to suppose them mere masses of matter unclothed with aught bearing analogy to our vegetable productions, and uninhabited by beings either sentient or rational, it will be difficult to see why any of the arrangements connected with these bodies, so far at least as they themselves are concerned, and apart from their attractive influence upon our own world, should be either beneficial or the contrary. It is solely on the conjecture that there are organised beings on their surface to be warmed, and nourished, and upheld, that we can argue regarding such arrangements; and making this conjecture, we shall find that there are some very remarkable apparent contrivances for ministering to their comfort and happiness. It has been supposed that a planet so far distant as Herschel, or even Jupiter or Saturn, must suffer from an extreme deficiency both of light and heat; and hence it has been argued that they are necessarily unfit for the sustenance either of animal or of vegetable life. But when we consider that even Herschel, the most distant from the sun, possesses 248 times the light afforded by our full moon, it will not be difficult to believe, that, with a somewhat more acute power of vision than we possess, the inhabitants of that planet, if formed like ourselves, may be quite able to engage in employments which require considerable minuteness of perception. Besides, to compensate for the deficiency of light derived directly from the sun to this planet in common with Jupiter and Saturn, there is afforded the subsidiary benefit of several moons or satellites to reflect light upon the surface when the sun has withdrawn his beams; neither is it probable that the inhabitants should miserably perish from cold; for putting out of view the possibility that they may be furnished with constitutions adapted to a more frigid climate than that of any portion of our world, we must remember that heat is not dependent altogether upon the body from which it originates, but is regulated in a very great measure by the nature of the body to which it is transmitted. Keeping this in view, the planet Mercury may be as cool, and Herschel as warm, as our own globe, although they be at such different distances from the great source of heat. This, however, can be

the subject of conjecture alone; and it is only valuable, as showing that we have no reason to suspect the goodness of the Creator in having placed some of his worlds in situations which, at first sight, might be supposed necessarily incapable of affording even the most essential accommodations to organic existences.

Of all the planets, Saturn presents us with the most singular example of design in reference to this subject. When viewed through a telescope, this beautiful orb is seen to be surrounded by a double circle of 30,000 miles distant from any part of its surface. This apparatus consists of two concentric rings, separated from each other by a space nearly 3000 miles in breadth, and moving round the planet at the extraordinary rate of a thousand miles a minute. Now, there is one use of this appendage, whatever may be its other purposes, which is very apparent; it must contribute much to enlighten and beautify the globe to which it is attached; and a very little reflection will show the effect it must have in this respect. What a magnificent brilliant spectacle must these rings present to the inhabitants of Saturn! During its more than fourteen years of summer, the night must be enlivened by the bright reflection of this brilliant arch extending its luminous curve from the eastern to the western horizon; while even during the day, the sun must be materially aided by it in shedding light upon the world to which it belongs. "There is no planet in the solar system," says a late writer, "whose firmament will present such a variety of splendid and magnificent objects as that of Saturn. The various aspects of his seven moons, one rising above the horizon while another is setting; a third approaching the meridian; one entering into an eclipse, and another emerging from it; one appearing as a crescent, and another with a gibbous phase; and sometimes the whole of them shining together in one bright assembly: the majestic motions of the rings, at one time illuminating the sky with their splendour, and eclipsing the stars; at another, casting a deep shade over certain portions of the planet, and unveiling to view the wonders of the starry firmament—*are scenes worthy of the majesty of the Divine Being to unfold, and the rational creature to contemplate.*" Of the other planets it is unnecessary individually to speak; our knowledge of them is extremely limited, and we may simply remark, that, in most of them, the same causes exist which in our globe produce the various seasons. To the causes of the seasons, further than that they are the result of the influences of the celestial bodies, we will not here allude. To the arrangement of these, and to the forethought and all-pervading knowledge and goodness of Him who designed them, are we, in a word, indebted for the opening beauties of spring—the full glow of summer, arrayed in flowers and clothed with verdure—the sober and sear leaves of autumn, with its aureate fields and happy harvests—and the cold but not desolate winter, which even in its frigidty serves a valuable purpose in the scheme of the natural world.

In these arrangements we see proofs of the care, the power, and the beneficence of that great Being who was the cause of all things. To what else, indeed, shall we trace the primary fact, that, of all the heavenly bodies connected with our system, the sun alone, situated as he is in the centre, possesses undivided light, while the planets which surround him are all dark bodies receiving their light from him? There is no reason, in the nature of things, why a body placed in the centre of a system should give forth light and heat, while those revolving round it should be destitute of them. And yet we find it to be so: and we perceive the consequence of this arrangement to be not only most beneficial, but absolutely indispensable to the existence of the organised beings with which these orbs may be clothed or peopled.

But there is another view of the system of worlds to which our earth belongs, that strongly corroborates the existence of a creating and presiding Being. We mean the provision which is made for its perpetuity, notwithstanding the existence of so many conflicting forces

—any one of which, if the system were differently arranged to what we find it to be, might in the course of ages derange the relations which the different bodies composing it possess towards each other, and precipitate the whole into confusion, only equalled by that chaos from which, by might and power, it was called. It will hardly be necessary minutely to explain the causes by which the earth and the other planets are kept in a continual state of rotation round the sun; but as perspicuity is one of the chief objects at which we aim, a few words on this subject will not be out of place. Let it be understood, then, that in every body of matter there exists a certain tendency to rush towards every other body, and that the larger, and denser, and nearer, any two bodies are, the greater is that tendency, and it will easily be comprehended that the sun, the largest of all the bodies in our system, should attract every other orb with a degree of force regulated by the size, the density, and the distance of each; so that, had all these bodies at first been placed in a state of rest in the universe, they would immediately have begun to move towards the sun, and thus, in the course of time, would, one after the other, have reached and been amalgamated with him in the form of one vast and irregular mass. But at the creation, this result was prevented by communicating to the planets an impulse at right angles to the diameter of their orbits, which, combining with the force of attraction—that is, the power of the sun in drawing or attracting the planets towards himself—caused the planets to revolve round the sun. If each of the planets, however, were to revolve round the sun, with no other prevailing power to interfere with their motions except these two, viz. the attraction of the sun, and the original impulse at creation, they would of course continue as they are throughout all ages; but this is not the case. In the words of Mr Whewell, “each of them is acted on by all the rest. The earth is constantly drawn by Venus, by Mars, by Jupiter, bodies of various magnitudes perpetually changing their distances and positions with respect to the earth. The earth, in return, is perpetually drawing these bodies. What in the course of time will be the result? The cause acts perpetually, and it has the whole extent of time to work in. Is it not, then, easily conceivable, that, in the lapse of ages, the derangements of the planets may accumulate, their orbits may change their form, their mutual distances may be much increased or much diminished? Is it not possible that these changes may go on without limit, and end in the complete subversion and ruin of the system?” What might have been the case had the balance of power, so to speak, in our system, been differently disposed, it is not easy to say; but that all which is here suggested as possible, would actually take place, were a capricious or ignorant hand to interfere in the distribution of these forces, may assuredly be affirmed. We should soon have “years of unequal length and seasons of capricious temperature; planets and moons of portentous size and aspect, glaring and disappearing at uncertain intervals; tides like deluges sweeping over whole continents; and, perhaps, the collision of two planets, and the consequent destruction of all organisation in them both.” As the solar system exists, however, so nicely is it adjusted, that the deep inquiries of several of the philosophers of the last century, founded on the most complicated calculations, have shown that its arrangements are stable—that although there are and may be perturbations, there are invariably proportionate compensations; so that, whenever a maximum has been reached in the derangements of the system, it must necessarily begin to revert to its ancient order, and the restoration must in the end be as complete as was the derangement. It would require a hardihood greater than we can easily conceive to exist in the human mind, to view this subject, and to deny, after all, that a perfectly wise, beneficent, and powerful being, originally made and has since sustained and governed all things; for had the original impulse of which we have spoken been a little stronger or a little weaker—had the relative inclination of the orbits

of the planets to one another been greater—had one or more of them moved in a direction opposite to the rest—had any one of these causes operated, the whole solar system must sooner or later have been precipitated into chaotic confusion. Will any man, then, deny the proof here afforded of design and skill?

It is proper, before leaving the heavenly bodies, to advert to the fixed stars. If little be known respecting the planets, still less has been ascertained regarding these more distant bodies; but it is by no means an unedifying employment to contemplate, through them, the immensity of creation, and, thus elevated, to draw the conclusion that the Being by whom they originated must indeed be infinitely glorious. Had there been no other design on His part than thus to strike the mind of man with a sense of His magnificence and grandeur, no surer method could have been adopted to impart the lesson. The mind is bewildered when it dwells upon the glories which astronomy develops; and it cannot find words lofty enough to express its sense of the intelligence it discovers, or the proofs of the power and wisdom and goodness it perceives.

RELATIONS BETWEEN MAN AND EXTERNAL NATURE.

Leaving the evidences of design that are to be deduced from the contemplation of the heavens, let us regard some of the relations that exist between man and external nature, and consider the wonderful adaptations to each other which they exhibit. There can be no blank in nature, and, consequently, no body is isolated; all more or less influence each other, and it is of some of these relative influences that we are about to speak. Man is attached by the laws of gravitation to the earth which he inhabits, and is surrounded by an atmospheric medium capable of exercising certain influences upon him; these influences are modified by the Almighty Power to be subservient to his wants, and designed to be adapted not only to his necessities, but to those of every living thing, whether plant or animal, that exists. The air which surrounds us exercises, in consequence of its extent, a pressure on the human body equal to about 33,600 pounds. But why do we not sink and miserably perish beneath this immense weight? It is by the re-action of the elastic fluids contained within our bodies that we are enabled to support so enormous a pressure. Here we find a mutual relation between us and the air, which cannot be interrupted without mutual injury. Suppose this weight to be withdrawn from our bodies, what would be the result? The expansibility of the fluids contained within us would have no restraint; they would dilate, burst through the solids which contain them, and destroy the individual. Place any animal beneath the receiver of an air-pump, and withdraw the air, the result is very apparent. One of the causes of the inconveniences that are experienced when on the summit of a very high mountain, is, that the air is less dense, and does not oppose so much pressure to the body; and this it is which occasions the violent bleedings from the ears, eyes, and mouth, that sometimes attack those so situated. The effect of a cupping-glass, when applied to the skin, has the same cause. We feel more or less the effects of any sudden change of atmospheric pressure, but still the density of the air is well adapted to the wants of man; had it been greater, our energies would have been oppressed as by an unnatural load; and if less, insufficiently sustained as by a defective support. The senses of hearing and smelling, too, which depend for their perfection on a medium density of the air, would have been either insupportably intense or defective. Again, the atmospheric pressure materially affects temperature. If a certain quantity of air contains a certain quantity of heat, it is clear that it must be equally diffused throughout it; and if the same air be contained in less bulk, or if the pressure be greater, the heat is increased in the same ratio. In the same manner, if the pressure be lessened, the air expands, and with it the heat is diffused over a greater surface. By compressing air, we can produce a sufficient con-

centration of heat to cause ignition. This influence of the air upon the body is as universal as the former, and the adaptation of the one to the other as constant. With the exception of some countries near the equator, and there only in the hot season and the middle of the day, the temperature of the atmosphere is always below that of man; and as heat always tends towards an equilibrium, it is obvious that a constant subtraction of heat from the body must be going on. Now, we are so organised as to allow of this universal subtraction; and, indeed, were it suddenly stopped, or even diminished, we should soon perish. Again, if the subtraction became increased, or went on more rapidly than the vital principle could replace it, our temperature would sink, our humours and fluids freeze, and in this case, too, we should soon perish. But there are intermediate points between these two extremes; and as we before said, our organisation is such that it adapts itself to the degree. All organic bodies are capable of resisting to a great extent, and of modifying the action of, heat and cold; indeed, this principle of self-preservation is in them so striking as to have been regarded from a very early period as the most essential attribute of life. The power possessed by the higher classes of animals, of preserving a more or less uniform degree of heat, is almost unlimited. In very cold climates the thermometer not unfrequently sinks to 50° or 55° below the freezing point, while in very hot ones it is sometimes 120° or 125° above it, making a difference of 170° or 180° ; still, however, the temperature of the body remains unchanged. What unanswerable evidence of design is this, and how limitless must be that Power who could create such wonderful adaptations!

If the atmospheric pressure produces in some measure the regulation of heat and cold, in no less degree does it affect moisture and its concomitants—clouds, mist, rain, snow, and hail; and thus we are dependent for many of our comforts, and for most of our necessities, upon the due adjustment of atmospheric influences. Winds, too, arise from any unwonted atmospheric pressure disturbing the equilibrium of the atmosphere, and are the efforts of nature to restore the balance. All the changes of weather, the most violent storms and tempests, own the same cause.

Connected with this subject, as evidencing design, is the composition of the air, which is precisely that best adapted to support respiration. It consists, besides small proportions of aqueous vapour and carbon, of two fluids, or gases, called oxygen and nitrogen. In a separate state these gases are inimical to life. Lavoisier proved by experiment that pure air, or oxygen gas, if respired for a certain time, rarifies the blood too much, and increases the rapidity of the circulation, the effects of which are violent fever, inflammation of the lungs, and death. Nitrogen is equally destructive to life, as not yielding that principle on which the purification of the blood depends. It is their combination that renders them salutary to the constitution, neither consuming life by too much stimulus and excitement, nor deadening its energies by a languid circulation and depression of spirits. Why should the air have been composed exactly of twenty-one parts of oxygen and seventy-nine of nitrogen? Why were all other proportions excluded? It could not have been owing to a blind and fortuitous chance. The fact that we find two deadly ingredients so united as to become not only harmless but salutary, must strike every mind with an unanswerable evidence of design. Atmospheric air is absolutely necessary both to animal and vegetable life, and both classes of beings are fully adapted for its reception. The boldest Epicurean could scarcely imagine that so necessary a substance has by mere chance surrounded this globe for the support of its inhabitants, upon whom, without it, God would have bestowed his power and wisdom and goodness in vain; nay, even had men, according to the doctrine of Epicurus, sprung up like mushrooms from the earth without an atmosphere, they could not have existed upon it. Has not, then, the hand of a wise Creator been here visibly employed,

or why were we supplied with instruments that render the air available to us?—enabling us to resist its dreadful pressure, and to avail ourselves of its unutterable advantages. If we contemplate for a moment the evils which would have followed had not divine intelligence presided at the constitution of our globe, and placed an atmosphere around it, how fearful and dreary it would have been! The moon has no atmosphere, and hence its climate must be very extraordinary; either the fiercest sunshine must reign, or the keenest frosts endure. If our earth had been similarly situated, no organic being would have adorned its surface; neither plant nor animal could have existed; no reflection of light could have taken place; no dawn or twilight would have prepared us for morning or for night; a dome blacker than darkness would have surrounded the earth, and light only have become manifest when the eye received it directly from the sun. The blue sky which now surrounds us, and which is owing to the thin watery vapours floating in the atmosphere, and reflecting peculiar rays of light, the blue and the violet, would not have been there. And where can we find such evidences of design as the blue colour which the sky exhibits! Of all hues we could imagine, is there any to surpass that mild and soft ethereal tint, harmonising with all around us, and on which the eye, fatigued with more brilliant and dazzling objects, turns for relief and repose? The unbeliever may say that this colour was the result of chance; but suppose any other, a bright yellow, a dazzling white, a glaring red, a fearful colour, how uncomfortable and painful would it have been for the vision of man! Again, an atmosphere is necessary to hearing; it enlarges the field of vision, and contributes also to the means of smell; and not only do the beings on earth enjoy life through its means, but it contributes to the sustenance of the finny tribes, enabling them not only to exist, but to rest in the water, or ascend and descend in it in quest of food.

There are still other relations existing between man and external nature, to which we would shortly allude as illustrative of design; and they are such, that without them certain important functions could not be performed, and, consequently, man could not exist. These relations, which may be termed *organic*, are the more numerous and necessary to life, as the organisation of the individual is the more developed or complete; and while they may be all included in the two functions of nutrition and sensation, they are the more multiplied as the operations of the former are more complex, and the extension of the latter greater; and hence they are more numerous in man than in any other animal. As in the physical relations, to some of which we have already alluded, so in the organic we must assign the first rank to the atmosphere, so necessary to life, and so admirably adapted to sustain it. It is the medium, also, through which we receive heat, light, and electricity, of which we appear to be as much in need as of that principle of air which purifies our blood, and fits it for the performance of its several operations. These matters are inherent in all living bodies; and if simple elementary bodies do exist, these are they. Many physiologists recognise the greatest analogy between the nervous fluid and electricity, and there is great reason for believing that it assists considerably in the maintenance of the vital phenomena. We know, however, that all these agents exercise a great influence upon life, from the demand that living bodies make upon them. Observe how plants languish and become weak when deprived of light, and how solicitously they move in the direction that will the most expose them to its invigorating influence. Nor is it less necessary to animal existence. Eggs cannot be hatched when deprived of it; and the transformations to which many insects are exposed, go on more slowly when in a darkened place. But let us suppose that this element was only given for the purpose of enlightening the earth, what a wonderful relation, then, does it bear to the eye which perceives it! No one who considers the eye attentively can resist the impression of the evidence of

design and skill which its construction exhibits. At the same time, it must be obvious that this construction of the eye would not answer its purposes, unless the constitution of light corresponded to it. Light is an element of the most peculiar kind and properties, and such an element can hardly be conceived to have been placed in the universe without some regard to its operations and functions. As the eye is made for light, so light must have been made, at least among other ends, for the eye. What we have said of light is equally applicable to heat. It is obvious that the vital energy of plants is much diminished, even suspended, during winter, while with the return of summer they again shoot forth their leaves and flowers; the same alternation obtains also among hibernating animals. Heat is evidently the cause of these changes; so much so, indeed, that vegetables may be forced to invert the order of the seasons. The climates in fact demonstrate the influence of heat. How stunted is both animal and vegetable life in polar regions, and how exuberant do the same individuals become under warmer skies! Electricity undoubtedly exists in the atmosphere in all its states; but we know very imperfectly the laws of this agent, and are still more ignorant of its atmospheric operation. The present state of science, while it permits us to hazard an opinion, does not enable us to perceive those adaptations of its laws to its uses, which we can discover in those cases where the laws and the uses are both of them more apparent. "It is at any rate very probable," says Whewell, "that electricity has its important purposes in the economy of the atmosphere. And this being so, we may see a use in the thunderstorm and the stroke of the lightning. These violent events are, with regard to the electricity of the atmosphere, what winds are with regard to heat and moisture. They restore the equilibrium where it has been disturbed, and carry the fluid from places where it is superfluous, to others where it is deficient. We are so constituted, however, that these crises impress every one with a feeling of awe. The deep lowering of the gloom of the thunder-cloud, the overwhelming burst of the explosion, the flash from which the steadiest eye shrinks, and the irresistible arrow of the lightning which no earthly substance can withstand, speak of something fearful, even independently of the personal danger which they may whisper. They convey, far more than any other appearance does, the idea of a superior and mighty Power, manifesting displeasure and threatening punishment. Yet we find that this is not the language which they speak to the physical inquirer; he sees these formidable symptoms only as the means or the consequences of good. What office the thunderbolt and the whirlwind may have in the *moral* world, we cannot here discuss; but certainly *he* must speculate as far beyond the limits of philosophy as of piety, who pretends to have learnt that these work more of evil than of good. In the *natural* world, these apparently destructive agents are, like all other movements and appearances of the atmosphere, parts of a great scheme, of which every discoverable purpose is marked with beneficence as well as wisdom."

We think we have now sufficiently shown the wonderful adaptations and relations that exist between some of the phenomena of external nature and organised existences. It does not accord with our purpose to enter deeply or at greater length into the subject, but even the little we have said, must, we hope, carry with it the conviction, that verily it is a God who made and rules the universe.

DESIGN IN THE STRUCTURE OF THE EARTH.

It is evident, even on a very casual inspection, that the surface or crust of the globe we inhabit has undergone many changes, and these both great in extent and of long duration. Two agents, fire and water, have been mainly instrumental in their production. The ocean, the great source of aqueous influence, seems, from time immemorial, to have been engaged in a struggle to degrade or level the surface of the earth,

not only by the direct action of its tides and currents upon coasts, but also by means of the clouds of vapour which it sends up into the atmosphere, and which redescend on the earth in the shape of rain and snow, giving rise to numberless springs and rivers, all of which have some effect, less or more, in washing down the dry land. This system of detrition, carried on from age to age, would have produced a state of things very different from that which now exists, had it not been for the antagonising agency of fire, which, working from the centre outwards, either by extensive convulsions or by slow upheavements, has elevated and repaired the earth's surface as fast as the waters have abraded it, and has compelled the ocean to give back to the light, in the form of continents and islands, the materials which it had before swallowed up.

In this reciprocal action and counteraction, and in their effects upon the earth's surface, we find abundant proofs of benevolent design. By these means have been produced those extensive irregularities—that diversity of hill and vale, ridge and plain—on which depends the fitness of the earth for the maintenance of all organic life, whether animal or vegetable. If the surface were level and smooth, the vapours raised from the sea by the sun would find no channel for their return, and the globe would necessarily become a stagnant marsh, unsuited for the residence of man and the greater part of the creatures that now tenant it along with him. But even if man could have inhabited the earth without its existing irregularities, how few comparatively would have been the advantages of his position! Had the matters carried down and deposited in the early seas, in the form of chalk-beds, limestone-beds, and coal-beds, with all the treasures of minerals and metals accompanying them, remained where they were first accumulated, man would have lost all the most essential elements of industry and civilisation. The changes and disruptions which have taken place in the crust, have brought to light a fund of riches, without which he would have been poor in comforts and in arts. Looking to those vast coal-fields alone, which the crust of our globe contains, can we imagine for a moment that the great changes by which these ruined forests of the primeval world were first spread out and moulded into new forms, and then upheaved to the reach of man, to supply him with endless stores of heat, light, and wealth, were produced by blind chance, or by aught but a creative designer, a being equally great and good?

On examining further into the condition of the earth's crust, as established by the changes it has undergone, we find numerous other proofs of the wise foresight which has ordered and arranged the whole. We discover that all the successive mutations of our planet, extensive as they have evidently been, were rendered compatible with the existence and enjoyment of countless numbers of organised and sentient beings. All the rocky strata of the crust, with the exception of those which appear to be the oldest and deepest-seated, are mixed up abundantly with organic remains, both animal and vegetable, and indeed some of the great limestone-beds are found to be entirely composed of the shells of insects. In short, whatever was the state of the surface at any given period of the revolutions fitting it for the ultimate residence of man, we find organised beings to have sprung up upon it, with such habits and peculiarities of structure as enabled them to exist and enjoy existence under the peculiar circumstances in which they were placed. Nothing can more distinctly show that our planetary revolutions had a noble scope and purpose, and were under the guidance of laws framed by a being as benevolent as wise.

DESIGN IN ANIMAL PHYSIOLOGY.

The earth, whose structure we have just briefly noticed, serves as the place of habitation for two kinds of existences—the animal and vegetable—in whose formation and functions we discover the beautiful dispensations of Providence, extending on every side over a vast range of beings, and demonstrating the unity of

plan on which organised creation has been devised. And, first, the whole circle of our knowledge does not afford greater evidence of design than comparative anatomy: in it we find innumerable contrivances for the comfort and happiness of the different tribes of beings adapted to the peculiarities of their condition; in each animal we see the same organ repeated, but modified to render it more available to the habits of its possessor; and among all the wonders of creation, there are none which strike the inquiring mind more forcibly than this change or modification of formation for the obvious purpose of accommodation to circumstances. Were all animals formed alike, or did the differences which exist between them bear no relation to their habits or destinies, it would be less easy to refute the doctrine which assigns all things to material causes, and excludes the designing hand of an intelligent Creator. Although even then the argument would be totally untenable, still the demonstration which disproves it would have been less satisfactory and perfect, as the surprising skill and beneficent care by which the structure of every animal is adapted to its individual habits and necessities, could not have been so well displayed. A single tool in the hands of the carpenter is a proof of contrivance, but that proof is much multiplied and rendered more forcible when we find the same instrument modified into a thousand forms to suit the different operations of the workman. Few of the functions of animated beings better illustrate this than that of alimentation, which we shall now briefly trace, through the humble zoophytes and worms up to birds and mammiferous animals. Nutrition is common to all animals without exception; and the numerous and varied modifications of the means employed to effect it, are obvious proofs of the design and intelligence of the Creator. There are some animals so nearly allied to plants as to be scarcely distinguishable from them; and in these, as in plants, nutritive matter is introduced by mere imbibition. Fixed like plants to the spot where they grow, any other organs would have been superfluous; while to those which are not so attached, but seek their food and obtain it through their locomotive powers, organs for seizing and preparing it are necessary. In them, therefore, we find lips variously and curiously modified; glands about the mouth for furnishing fluids for lubricating dry alimentary matters; a tongue, or something analogous to it; teeth and jaws for breaking down hard substances, and rendering them fit for swallowing; with a passage called the *œsophagus*, or gullet, leading from the mouth to the stomach, in which the food is at last assimilated, and rendered fit for nourishing the animal. But it is not until we advance some way in the great chain of animal life that these parts become sufficiently obvious, or their offices clearly defined. In the very lowest orders, the mouth and stomach are one continuous tube, or all stomach, as it may be called, and so simple in construction, that the animal may be turned inside out without detriment to it; that which was external being now internal, and performing, apparently with equal facility, all the offices of what was previously the stomach. As we advance, however, we find the nutritive organs ceasing to be a mere sucking apparatus, or a receptacle for imbibed fluids. In those whelks which are furnished with proboscides, we find a cavity occupied by the aperture of the *œsophagus*, a tongue, and teeth; while the snail possesses a perfectly formed mouth and lips. Among the worms, whose stomachs are generally membranous bags, we find examples of wonderful contrivance and design. Thus, the powerful stomach of one species contains three hard calcareous shells, by which the individual is enabled to bruise and masticate the shelled animals on which it feeds. The discoveries of Ehrenberg respecting the animalculæ inhabiting different vegetable infusions, have extended, in an extraordinary degree, our knowledge of the stupendous power of God; and the inimitable proofs of design displayed in beings to whom, in relative size, the mite is as an elephant, afford astonishing displays of a minute and most

beneficent attention to the preservation of these curious creatures, in whose organisation and instincts new and admirable indications of creative wisdom are revealed. By the aid of the microscope, we are enabled to perceive the Creator of the universe minutely busy among the worlds of living creatures to which he has given birth on a blade of grass, or in a drop of water, and to discover fresh scenes of wonder, and interest, and evident design, among hosts of animated beings, infinite in number as in minuteness. These discoveries, of which an able analysis was lately given by Dr Gardiner in the *Edinburgh New Philosophical Journal*, have dissipated the obscurity in which the animalculæ were plunged, and displayed the wonders of their organisation. To render their digestive organs more conspicuous, he supplied them with coloured food, which communicated its tinge to the cavities through which it passed. The moment a minute particle of a highly attenuated solution of pure indigo was applied to the drop of water on the field of the microscope, in which were some of the infusory animalculæ, the most beautiful phenomena presented themselves. Presently their bodies, which had been hitherto quite transparent, became dotted with a number of spots of a dark blue colour, evidently produced by particles of indigo accumulated in these situations. In some species, particularly those which had a contracted part, or neck, between the head and the body, these particles were to be traced in a continuous line in their progress from the mouth to these internal cavities. In this way, by the employment of colouring matters, Ehrenberg succeeded in ascertaining the existence of a system of digestive cavities in all the known species of this tribe of animals: one of the largest of which he found to possess a highly complicated structure with regard to many organs: with respect to the nutritive function, he found a head provided with a regular apparatus for mastication, consisting of jaws having from two to six teeth, which were seen actively opening and shutting when the animal was taking its food.

As we ascend higher in the scale of existence, we find the digestive apparatus ceasing to be simple cavities, or canals hollowed out of the substance of the body, and becoming distinct organs formed by membranes and coats proper to each; and among these, the first example occurs in the sea anemone, in which we find spaces intervening between the coats of the stomach and the skin of the animal: here, however, the stomach is still a blind pouch, one aperture serving alike for receiving and ejecting the alimentary matters. In the *echini* or sea-urchins these organs are still more perfect. Those of mastication are peculiarly developed; an *œsophagus* or gullet also presents itself, and a stomach continued into a regular intestine, which takes two turns in the body before it terminates.

DESIGN IN THE FORMATION OF INSECTS.

In the digestive organs of insects we meet with a multitude of new and peculiar formations, while most of the simple forms found in the lower animals are here repeated. The organs of mastication, deglutition, and suction, present such remarkable differences, that the arrangements of modern systems of entomology have been chiefly founded on them. In this order of animals, nutrition by vegetable substances is much more common than in those below it; indeed, as Blumenbach has observed, the business of nutrition in insects does not seem to have for its object the mere preservation of the individual, as in most red-blooded animals, but chiefly the consumption of organised matter, which will appear from considering the structure of their alimentary canal. In most of those which are subject to a metamorphosis, the stomach in the larva state is of a great size in comparison with the short intestinal canal; while those, on the contrary, which take little or no nourishment in their perfect state, have this organ remarkably diminished, and, as it were, contracted. How beautifully does the great size and straight course of the intestinal apparatus of the animal, when in its caterpillar state,

coincide with its enormous voracity and quick digestion! It has been computed that caterpillars sometimes devour and digest no less than three times their own weight of aliment in four-and-twenty hours. On the other hand, during the subsequent metamorphosis which the animal undergoes, no food is taken; but nature, or rather the God of nature, has wonderfully, and with beneficent design, provided against any necessity for this, by causing insects to become very fat, as observed by Malpighi, on the approach of these changes; so that this fat, being absorbed into the blood while these are going on, serves all the purposes of a supply of alimentary matters from without. The insects now under consideration exhibit at different periods of their existence the greatest contrasts, not only in external form, but also in their habits, instincts, and modes of subsistence. The larva, as we have seen, is remarkable for its voracity, requiring large supplies of food, and consuming enormous quantities of vegetable matter; the perfect insect or butterfly, having attained its full dimensions, is sufficiently supported by small quantities of a more nutritious food, consisting either of animal juices or of the fluids prepared by flowers, which are generally of a saccharine quality, and contain nourishment in a highly concentrated form. It is evident that the same apparatus which is necessary for the digestion of the bulky food taken in during the former period, would not be suited for the assimilation of that which is received during the latter; and that, in order to accommodate it to this altered condition of its function, considerable changes must be made in its structure. Who can believe that these changes are made without wisdom, or persuade themselves that all this is to be brought about by causes divested of knowledge and understanding? Dr Roget, in his admirable Bridgewater Treatise, has beautifully illustrated the subject, by very clear and correct drawings by Mr Newport, of the three different states of the entire alimentary canal of the privet hawkmoth (*Sphinx ligustri*): first, when a caterpillar; then as a chrysalis; and, lastly, as the moth; and of these, taking our text from Roget, or rather from Herold, we shall endeavour to give some account. We have seen that in the caterpillar the stomach forms by far the most considerable portion of the alimentary canal, bearing some resemblance in its structure and capacity to the stomachs of certain worms. This is followed by a large but short and perfectly straight intestine. In the chrysalis, these organs have undergone considerable modifications; the whole canal, but more especially the stomach, being contracted both in length and width: the shortening of the intestine not being proportionate to that of the whole body, obliges it to be folded upon itself for a certain length. In the moth, the contraction of the stomach has proceeded much farther, and an additional cavity, which may be considered as a kind of craw, is developed; the small intestine takes a great many turns during its course, and a large pouch has been formed at the part where it joins the large intestine. "When we consider," say Kirby and Spence, speaking of the phenomena which we have detailed, "the adaptation of all these changes of form, the loss of old organs and the acquisition of new ones, to the functions and mode of life of the animal, we see evidently the all-powerful hand of that Almighty Being who erected the universe, upholding by his providence, and the law that he has given to every creature, the system that he at first brought into existence."

In insects, all parts concerned in digestion are in general smaller and less complicated in the carnivorous than in the herbivorous tribes, apparently from the matters on which the former subsist being already animalised, and requiring, therefore, less preparation before they are received into the blood; and it is no slight indication of design, to observe in them how admirably parts are adapted to the animal necessities. Thus, scorpions, spiders, millepedes, and others which live for the most part on hard animal substances, are furnished with jaws of a firm horny texture, in many

cases very large, when compared with the size of the animal; dragon-flies and beetles, particularly the stag-beetle, are examples in which the jaws are very large and manifest, often possessing tooth-like edges; and these, too, feed on smaller insects than themselves. In another description, of which the bee, wasp, and ant, are examples, we find the animal deserting the coarser kinds of food, living chiefly on juices; and in them also we again find the same mode of taking in nourishment, as in the lowest stages of the animal kingdom, viz., by means of organs of suction, which here, however, are combined with organs for mastication. These organs of suction are still more developed in insects, such as gnats, house-flies, &c.; in them they consist of a tube, of which the sides are strong and fleshy, and moveable in every direction, like the trunk of an elephant, and having at its extremity a double fold, resembling lips which are well adapted for suction. The gnat, and other insects which pierce the skin of animals, have for this purpose instruments termed *langets*, from their shape and office. In the gnat they are five or six in number, finer than a hair, exceedingly sharp, and generally barbed on one side; while in the house-fly they are flat, like the blade of a knife. In the butterflies, however, which are almost wholly independent of solid nutritive matter, these organs present themselves in the greatest perfection, and without any addition of teeth. The proboscis of this order of insects is a double tube, constructed by the two edges being rolled longitudinally till they meet in the middle of the lower surface, thus forming a tube on each side, but leaving also another tube, intermediate to the two lateral ones. This middle tube is formed by the junction of two grooves, which, by the aid of a curious apparatus of hooks, lock into each other, and can be either united into an air-tight canal, or be instantly separated at the pleasure of the animal.* It would be quite incompatible with the nature of this essay to enter at greater length into the evidences of design, deducible from the digestive apparatus of insects. "This immense class," says Cuvier, "in the structure of their alimentary canal, exhibit as many variations as those of all the vertebral animals together: there are not only the differences that strike us in going from family to family, and from species to species, but one and the same individual has often a canal quite different, according as we examine it in its larva or imago state;† and all these variations have relations very exact, often easily estimable, with the temporary or constant mode of life of the animals in which it is observable." That this statement is correct, we have seen; and no one can be blind enough to deny that it evinces an origin of things quite incompatible with mere brute and uncertain chance.

DESIGN IN THE FORMATION OF FISHES.

Still ascending in the scale of creation, we come to the contemplation of fishes. We ask, was it by mere chance that the respiratory apparatus of fishes was so formed that their blood receives its vivifying principle from the air which is held in solution by the water in which they move? And who cannot, in this one instance, but discern the hand of a ruling Providence, adapting the structure of animals to the habits which are to characterise them? Was it by chance that, in the plaice, the sole, the turbot, and other flat fishes, the eyes are placed both on one side of the body, an isolated instance of a want of uniformity in the two sides? No; the design is obvious: for as these animals are destined to continue always with one side in the mud at the bottom of the water, an eye on this side would have been superfluous and inconvenient to them. The same design and evident adaptation of structure to circumstances is apparent in the Surinam sprat. This singular animal generally swims so near the surface, that its eye is partly in and partly out of the water; and all its parts correspond with this strange peculiarity, the pupil being partially divided into an upper and a lower portion, and

* Roget, ff. 114.

† Imago or perfect state.

the lens consisting of two globes, an upper and a lower one attached together. It appears that the superior part of the eye is, like that of terrestrial animals, adapted to refract rays transmitted by air, and the inferior part, like that of aquatic animals, those transmitted by water, and that the refracting power of the several parts of the eye is accordingly much less above than below. With regard to the function of hearing, we find in fishes the Creator still proceeding on one vast plan or unity of design; with the exception of one species, all the parts of the ear are buried within the skull, and send no process to the surface; and this is precisely what we should have looked for in beings destined to hear through the medium of water, the vibrations of which being so much more powerful than those of air, would render the complicated apparatus requisite in terrestrial animals in them superfluous. In the class of fishes, we see the lowest condition of the alimentary canal as it is found in vertebral animals. Fishes, voracious to a proverb, subsist almost entirely on animal food. The ocean teems chiefly with animal life. It is a dense, and rich, and moving, and tempestuous element, where vegetation is comparatively small, contrasted with its development in the light and unresisting element of the atmosphere. This rich and resisting element of water abounds in every latitude and in every drop, with all forms of animated beings. Thus, fishes have the means of easily satisfying their voracious appetites with a selection of all kinds of food. Their teeth, more instruments of prehension than mastication, are sharp, recurved, dense, and pointed cones, adapted to grasp and retain every living thing that moves in the waters, and placed in all parts of the mouth of these all-devouring animals; their œsophagus or gullet is very wide and short, and directly opening into their capacious stomach. Thus, the food of fishes not being masticated in the mouth, does not dwell there; and as they are surrounded with an abundance of moisture, they require no salivary glands for lubricating the food, and they have none. Like larvæ, their stomachs are very large; and like them, also, they are chiefly intent upon the gratification of their appetites. All other senses seem to be absorbed in this. Their brain is very small, and their senses correspondingly obtuse.* The intestine of fishes varies considerably in length, according to the kind of food; but, generally speaking, it is not longer than their bodies; whereas, in most reptiles—which compose the next class of animals in the ascending scale—it is considerably longer; a provision unnecessary in fishes, perhaps, from the matters on which they for the most part feed, being almost always of the same nature as their own bodies, and therefore requiring comparatively little preparation.

Relinquishing our plan of illustrating design by an account of the digestive apparatus, let us consider, in reptiles, the organs subservient to the function of respiration, which, though somewhat similar to the organs designed for that purpose in birds and mammiferous quadrupeds, differ from those in some remarkable particulars. In reptiles, indeed, as in birds and mammalia, there is a kind of lungs; but they are membranous and not fleshy; that is to say, the cells which they contain are so much larger as to give them a membranous and not a fleshy appearance; nay, in many reptiles the lungs consist of one membranous bag, very similar to the air-bladder of fishes. These lungs or bags are situated in the abdomen, and are loose and floating among the entrails; and they receive their supply of air, in general, not as in birds and mammiferous animals, in consequence of the formation of a vacuum around them, but by a process very similar to that of swallowing. Hence, reptiles, unlike the higher classes of animals, can still continue to breathe if their bodies are cut open, because they do not require a vacuum round the lungs. The air thus received is subservient to the purification of the blood in the usual manner; but it is not so immediately viti-

ated as air received into fleshy lungs, owing to the larger size of the cells, which do not immediately allow the whole of it to come into contact with their sides. This is one reason why reptiles can sustain an impediment to their respiration for a much longer time than birds and mammals; but another and a much better reason is to be found in the distribution of their blood-vessels, those going to the lungs not forming a necessary part of the general circulating system, but constituting, as it were, only an appendage to it, which may for a time cease to transmit blood without inconvenience. A fish was destined always to be in the water, and a bird or quadruped always in the air; and hence the structure of their respiratory, as well as circulating system, is such as to incapacitate them each for the other element.

DESIGN IN THE FORMATION OF BIRDS.

We come now to birds; and whether we consider their external form or anatomical structure, or in whatever light it is possible to view them, the same conclusion presents itself to the mind. Inexhaustible contrivance, vast and comprehensive intelligence, are everywhere conspicuous. Behold, in their pointed bill, and gradually enlarging head and neck, a means of penetrating the yielding air; then the prow-like breast, the flexible rudder tail, the equiposed wings, and feathers at once adapted for lightness, for strength, and for tenacity, and all bearing relations, not only to each other, but to the air in which the animal is to fly: the wise contrivance of these could not be the result of chance. The investing membranes of their lungs, prolonged from various parts of their surface in the form of tubes, and expanding into bags, enveloping almost all the entrails, so as to keep them constantly surrounded with air, and similar prolongations extending also into the cavity of their bones, serving to inflate these in the same manner—are not these peculiarities for the obvious purpose of giving lightness to the animal, and thus enabling it to support itself in the air?—and does not this palpable subserviency of one part of the structure of birds to the rest, irresistibly inculcate the truth that one master-hand has regulated the whole?

In the beaks or bills of birds, various as are their forms, we can trace an exact adaptation to the food of the species. In those that tear their prey, as the eagle and hawk—or bruise hard fruits, as the parrot—or penetrate the bark of trees, as the woodpecker—the bills are of extraordinary hardness, and, in form, intimately connected with the habits of the animal. In those to whom a sense of feeling in this part is necessary to enable them to find their food in mud or water, as the duck, it is very soft, generally flattened, and so constructed that fluids may filter through it, while the solid food is retained. A bill hooked at the end, with sharp edges, characterises birds of prey. Another species of strong sharp-edged bill, of an elongated shape, but without a hook, serves to cut and break, but not to tear; and this is the form of the bill in birds which live upon animals which make resistance in the water; some of these are straight, as in the heron—others curved, some downwards, some upwards. Some sharp-edged bills have their sides approximating, like the blade of a knife to its handle, and thus adapted to seize small substances; as the penguin. The small, conical, arched bill of poultry, serves only to take up grain. The bills of the smaller birds present all the varieties of the conical form, from the broad-based cone of the hawfinch to the thread-like cone of the humming-bird. Such of them as have strong short bills live on grain; those with long thin ones, on insects. Where the bill is short, flat, opening very anteriorly, as in martens and swallows, the bird seizes flies and butterflies in the air; and if it be long and curved, possessing some strength, we find it grubs up worms for its food. The same evidence of design which we discover in the bills of birds adapting them to procure the kind of food on which the individual is to subsist, is apparent also in the conformation of their digestive organs. As the food of birds varies

from the softest animal matter to the hardest grain, so we observe every gradation in the structure of their stomachs, from the membranous sac of the carnivorous tribes to the true muscular gizzard of granivorous birds—varying according as the food consists of animal or vegetable materials, or presents more or less resistance from the cohesion of its texture.

In no branch of natural history do we find more remarkable evidences of design, than in the varieties of kinds of covering of animals adapted to their wants and situations on the globe. The covering of birds, in particular, “cannot (says Paley) escape the most vulgar observation. Its lightness, its smoothness, its warmth:—the disposition of the feathers all inclined backward, the down about their stem, the overlapping of their tips, their different configuration in different parts, not to mention the variety of their colours, constitute a vestment for the body, so beautiful, and so appropriate to the life which the animal is to lead, as that, I think, we should have had no conception of any thing equally perfect, if we had never seen it, or can now imagine any thing more so. Let us suppose (what is possible only in supposition) a person who had never seen a bird, to be presented with a plucked pheasant, and bid to set his wits to work how to contrive for it a covering which shall unite the qualities of warmth, levity, and least resistance to the air, and the highest degree of each: giving it also as much of beauty and ornament as he could afford. He is the person to behold the work of the Deity, in this part of his creation, with the sentiments which are due to it.

The commendation which the general aspect of the feathered world seldom fails of exciting, will be increased by further examination. It is one of those cases in which the philosopher has more to admire than the common observer. Every feather is a mechanical wonder. If we look at the quill, we find properties not easily brought together—strength and lightness. I know few things more remarkable than the strength and lightness of the very pen with which I am writing. If we cast our eye to the upper part of the stem, we see a material, made for the purpose, used in no other class of animals, and in no other part of birds; tough, light, pliant, elastic. The pith, also, which feeds the feathers, is, amongst animal substances, *sui generis*; neither bone, flesh, membrane, nor tendon.

But the artificial part of a feather is the beard, or, as it is sometimes I believe called, the vane. By the beards are meant, what are fastened on each side of the stem, and what constitute the breadth of the feather; what we usually strip off from one side or both, when we make a pen. The separate pieces or laminae of which the beard is composed, are called threads, sometimes filaments, or rays. Now, the first thing which an attentive observer will remark is, how much stronger the beard of the feather shows itself to be, when pressed in a direction perpendicular to its plane, than when rubbed, either up or down, in the line of the stem; and he will soon discover the structure which occasions this difference, viz. that the laminae whereof these beards are composed, are flat, and placed with their flat sides towards each other; by which means, whilst they *easily* bend for the approaching of each other, as any one may perceive by drawing his finger ever so lightly upwards, they are harder to bend out of their plane, which is the direction in which they have to encounter the impulse and pressure of the air, and in which their strength is wanted, and put to the trial.

This is one particularity in the structure of a feather: a second is still more extraordinary. Whoever examines a feather, cannot help taking notice that the threads or laminae of which we have been speaking, in their natural state *unite*; that their union is something more than the mere apposition of loose surfaces; that they are not parted asunder without some degree of force; that nevertheless there is no glutinous cohesion between them; that, therefore, by some mechanical means or other, they catch or clasp among themselves, thereby giving to the beard or vane its closeness and

compactness of texture. Nor is this all: when two laminae which have been separated by accident or force are brought together again, they immediately *reclasp*: the connection, whatever it was, is perfectly recovered, and the beard of the feather becomes as smooth and firm as if nothing had happened to it. Draw your finger down the feather, which is against the grain, and you break, probably, the junction of some of the contiguous threads; draw your finger up the feather, and you restore all things to their former state. This is no common contrivance: and now for the mechanism by which it is effected. The threads or laminae above mentioned are *interlaced* with one another, and the interlacing is performed by means of a vast number of fibres, or teeth, which the laminae shoot forth on *each side*, and which hook and grapple together. A friend of mine counted fifty of these fibres in one twentieth of an inch. These fibres are crooked, but curved after a different manner; for those which proceed from the thread on the side towards the extremity of the feather, are longer, more flexible, and bent downwards; whereas those which proceed from the side towards the beginning or quill end of the feather, are shorter, firmer, and turn upwards. The process, then, which takes place, is as follows:—When two laminae are pressed together, so that these long fibres are forced far enough over the short ones, *their* crooked parts fall into the cavity made by the crooked parts of the others, just as the latch that is fastened to a door enters into the cavity of the catch fixed to the door-post, and there hooking itself, *fastens* the door; for it is properly in this manner that one thread of a feather is fastened to the other.

This admirable structure of the feather, which it is easy to see with the microscope, succeeds perfectly for the use to which nature has designed it; which use was, not only that the laminae might be united, but that, when one thread or lamina has been separated from another by some external violence, it might be reclasped with sufficient facility and expedition.

In the *ostrich*, this apparatus of crotchets and fibres, of hooks and teeth, is wanting; and we see the consequence of the want. The filaments hang loose and separate from one another, forming only a kind of down; which constitution of the feathers, however it may fit them for the flowing honours of a lady's head-dress, may be reckoned an imperfection in the bird, inasmuch as wings composed of these feathers, although they may greatly assist it in running, do not serve for flight. ✕

But under the present division of our subject, our business with feathers is, as they are the *covering* of the bird. And herein a singular circumstance occurs. In the small order of birds which winter with us, from a snipe downwards, let the external colour of the feathers be what it will, their Creator has universally given them a bed of *black* down next their bodies. Black, we know, is the warmest colour: and the purpose here is, to *keep in* the heat arising from the heart and circulation of the blood. It is further likewise remarkable, that this is not found in larger birds; for which there is also a reason.—Small birds are much more exposed to the cold than large ones; forasmuch as they present, in proportion to their bulk, a much larger surface to the air. If a turkey were divided into a number of wrens (supposing the shape of the turkey and the wren to be similar), the surface of all the wrens would exceed the surface of the turkey, in the proportion of the length and breadth (or of any homologous line) of a turkey to that of a wren; which would be, perhaps, a proportion of ten to one. It was necessary, therefore, that small birds should be more warmly clad than large ones; and this seems to be the expedient by which that exigency is provided for.

The *oil* with which birds prune their feathers, and the organ which supplies it, is a specific provision for the winged creation. On each side of the rump of birds is observed a small nipple, yielding upon pressure a butter-like substance, which the bird extracts by pinching the pap with its bill. With this oil or ointment thus procured, the bird dresses its coat, and repeats the

action as often as its own sensations teach it that it is in any part wanted, or as the excretion may be sufficient for the expense. The gland, the pap, the nature and quality of the excreted substance, the manner of obtaining it from its lodgment in the body, the application of it when obtained, form, collectively, an evidence of intention which it is not easy to withstand. Nothing similar to it is found in unfeathered animals. What blind *conatus* of nature should produce it in birds? should not produce it in beasts?"

As we have entered so fully into this subject when treating of other classes of beings, we shall not here revert to it, or bring forward illustrations of the truth of our proposition; the facts already detailed seem sufficient to display the wisdom which the great Creator has evinced in this department of the animal world. Nothing can be more worthy of remark than the exhaustless contrivances by which every difficulty is obviated, and nature moulded to the will of its Almighty Author. How many obstacles were to be overcome before a heavy body like that of an eagle or the mighty condor could be rendered buoyant in the air, and made to track its adventurous course so high above the earth as to be almost lost to human gaze! How many conditions were necessary to give safety and enjoyment to the smallest of the winged tribes, even after the first obstacles were overcome! Yet how wonderfully simple and efficacious the means by which the whole has been accomplished! That man is indeed to be pitied who can turn even a transient glance on such a subject, without being lost in astonishment and admiration.

THE STRUCTURE OF MAN AND OTHER ANIMALS.

We now arrive at the consideration of the mammalia, or those animals which suckle their young; and at the head of this great class we find man proudly pre-eminent. We have already seen, that, as the materials on which the function of digestion is to be performed are numerous and diversified, so a difference exists in the parts which are subservient to it. Without altering the general plan of the function, or the essential parts of the organs concerned in it, nature makes such additional provisions, in the instincts by which the reception of food is guided, and in the organs by which it is assimilated, as are suited to the circumstances in which the animal is placed, to the food on which it is to subsist, and to the ulterior purposes which it is to serve in the world. Such evidences of design are very remarkable in the mammalia; and in few organs are they more powerfully instanced than in the teeth, between which, in form, structure, and position, and the kind of food on which each animal of this class is intended to subsist, the most intimate connections present themselves. These relations—which indeed may be also traced in the shape of the jaw, in the mode of its articulation with the head, in the proportional size and distribution of the muscles which move the jaw, in the form of the head itself, in the length of the neck and its position on the trunk, and, in fact, in the whole conformation of the skeleton—have been noticed from very early ages, and frequently described.

The purposes answered by the teeth are principally those of seizing and detaining whatever is introduced into the mouth, of cutting it asunder and dividing it into smaller pieces, of loosening its fibrous structure, and of breaking down and grinding its harder portions. Four principal forms have been given to teeth, which accordingly may be distinguished into the conical, the sharp-edged, the flat, and the tuberculated teeth; though we occasionally find a few intermediate modifications of these forms. It is easy to infer the particular functions of each class of teeth, from the obvious mechanical actions to which, by their form, they are especially adapted. The conical teeth, which are generally also sharp-pointed, are principally employed in seizing, piercing, and holding objects; such are the offices they perform in the crocodile and similar reptiles, where all the teeth are of this structure: and such also are their uses in most of the cetacea or whale tribe,

where similar forms and arrangements of teeth prevail. The animals subsist on fish, and their teeth are therefore constructed very much on the model of those of fish; while those cetacea, on the other hand, which are herbivorous, as the manatus and dugong, have teeth very differently formed.

The sharp-edged teeth perform the office of cutting and dividing the yielding textures presented to them: they act individually as wedges or chisels; but when co-operating with similar teeth on the opposite jaw, they have the power of cutting like shears or scissors. The flat teeth, of which the surfaces are generally rough, are used, in conjunction with those meeting them in the opposite jaw, for grinding down the food by a lateral motion, in a manner analogous to the operation of millstones in a mill. The tuberculated teeth, of which the surfaces present a number of rounded eminences, corresponding to depressions in the teeth opposed to them in the other jaw, act more by their direct pressure in breaking down hard substances, and pounding them, as they would be in a mortar.

The apparatus for giving motion to the jaws is likewise varied according to the particular movements required to act upon the food in the different tribes. The articulation of the lower jaw to the skull is somewhat similar to a hinge; but considerable latitude is given to its motions by the interposition of a moveable cartilage between the two surfaces of articulation, a contrivance admirably answering the intended purpose. Hence, in addition to the principal movements of opening and shutting, which are made in a vertical direction, the lower jaw has also some degree of mobility in a horizontal or lateral direction, and is likewise capable of being moved backwards or forwards to a certain extent. In the conformation of the teeth and jaws, a remarkable contrast is presented between carnivorous and herbivorous animals. In the former, of which the tiger may be taken as an example, the whole apparatus for mastication is calculated for the destruction of life, and for tearing and dividing the fleshy fibres. The teeth are armed with pointed eminences, which correspond in the opposite jaws, so as exactly to lock into one another, like wheelwork, when the mouth is closed, and the muscles which close it are of enormous size and strength. In the herbivorous animals, on the contrary, as in the antelope, the greatest force is bestowed, not so much on the motions of opening and shutting, as on those which are necessary for grinding, and which act in a lateral direction. The surfaces of the teeth are flattened and of great extent; and they are at the same time kept rough, like those of millstones, their office being in fact very similar to that performed by these implements of grinding. The *Rodentia*, or gnawing quadrupeds, are formed for subsisting on dry and tough materials, such as the bark and roots, and even the woody fibres of trees, and the harder animal textures; and their teeth are expressly adapted for gnawing, nibbling, and wearing away, by continued attrition, the harder texture of organised bodies. They are all furnished with two front teeth, generally very long, and having the exact shape of a chisel; while the molar or back teeth have surfaces irregularly marked with raised zig-zag lines, rendering them very perfect instruments of trituration. The beaver and rat are examples among omnivorous rodentia, and the hare and rabbit among those that are principally herbivorous.

The *Quadrumana*, or monkey tribes, approach nearer to the human structure in the conformation of their teeth, which are adapted to a mixed kind of food; while the other orders of mammalia exhibit gradations in the structure of their teeth corresponding to the varieties in the nature of their food. Thus, the teeth and jaws of the hyena are formed more especially for breaking bones, while those of the sea-otter have rounded eminences which peculiarly fit them for breaking shells.

"On comparing the structure of the digestive organs of man," continues Dr Roget,* "with those of other

* Bridgewater Treatise.

animals belonging to the class mammalia, we find them holding a place in the series intermediate between those of the purely carnivorous and exclusively herbivorous tribes, and in some measure uniting the characters of both. The powers of the human stomach do not indeed extend to the digestion of either the tough woody fibres of vegetables on the one hand, or the compact texture of bones on the other; but still they are competent to extract nourishment from a wider range of alimentary substances than the digestive organs of almost any other animal. This adaptation to a greater variety of food may also be inferred from the form and disposition of the teeth, which combine those of different kinds more completely than in most mammalia. In addition to these peculiarities, we may also here observe, that the sense of taste in the human species appears to be affected by a greater variety of objects than in the other races of animals. All these are concurring indications that nature, in thus rendering man omnivorous, intended to qualify him for maintaining life wherever he could procure the materials of subsistence, whatever might be their nature, whether animal or vegetable, or a mixture of both, and in whatever soil or climate they may be produced; and for endowing him with the power of spreading his race, and extending his dominion over every accessible region of the globe. Thus, then, from the consideration of the peculiar structure of the organs of his frame, may be derived proofs of their being constructed with reference to faculties of a higher and more extensive range than those of any, even the most favoured, species of the brute creation."

There is one circumstance connected with the function of digestion, as displayed in certain of the mammalia, to which, as evidencing great and wonderful design and accommodation in structure to circumstance, we would particularly allude; it is the facility and power of the camel of abstaining long from drinking—a power which he is often necessitated to bring into effect during the long period of nine, ten, or even twelve days. In Arabia, the camel is the chief beast of burden; and in travelling through such a country, it is only at long intervals that water can be obtained; a country, as described by Buffon, without verdure, without water, possessing a burning sun, an air always parched, sandy plains, mountains still more scorched, which the eye runs over without perceiving a single animated being; a dead earth perpetually tossed with the winds, and presenting nothing but bones, scattered flints, rocks perpendicular or overturned; a desert totally void, where the traveller never breathes under a shade, where nothing accompanies him, nothing recalls the idea of animated nature; absolute solitude, more dreadful than that of the deepest forests, more solitary and naked, more lost in an unlimited void; he everywhere beholds space surrounding him as a tomb. The light of day, more dismal than the darkness of night, serves only to give him a clearer view of his own wretchedness and impotence, and to conceal from him the barriers of the void, by extending around him that immense abyss which separates him from the habitable parts of the earth; an abyss which in vain he should attempt to traverse, for hunger, thirst, and scorching heat, haunt every moment that remains to him between despair and death. Frightful as is this picture, the desire of lucre, or the gratification of curiosity, and a love of enterprise no less insatiable, often tempt men to traverse the sandy deserts of Arabia. For their own necessities they may provide, but no human means could afford the possibility of conveying water sufficient to satisfy the longings of the beasts of burden which accompany these expeditions. It is by the singular structure of the camel's stomach that it is enabled to pass several days without drinking, and to take at a time a prodigious quantity of water, which remains in reservoirs pure and limpid, because these wells are so contrived that neither the fluids of the body nor of digestion can mix with it. What design is here!—and how redolent of wisdom, and how full of mercy! But let us endeavour to explain

the nature of this structure which so evidently adapts the camel to be the inhabitant of the sterile and arid regions of the east:—Ruminating quadrupeds, or those which chew the cud, have two, three, or four stomachs, distinguished, when there are four, by the names of paunch, bonnet, many-plies, and caille. When the food is swallowed for the first time, it passes directly from the gullet into the paunch, where it undergoes some necessary changes, and it is then transmitted to the bonnet, to be mixed with the fluids of the cavity. This process is going on during the time the animal is grazing, when from the incessant occupation of nipping off the grass, for which its teeth are so admirably suited, it has not leisure to chew it sufficiently. When afterwards reposing itself, however, the half-chewed aliment is brought again in successive little balls, from the bonnet into the mouth, where it is subjected to a perfect mastication; and when again swallowed, it passes directly to the many-plies, thence, after some time, to the caille, and ultimately to the intestines. In the camel, however, the paunch has two deep cellular appendages; and the bonnet, or second stomach, has its internal membrane hollowed into numerous deep cells, serving as reservoirs of water, to be used only as occasion requires; while the third stomach is alone appropriated to the immediate necessities of the body. Between the end of the gullet, then, and the orifice of this third stomach, extends, through the two first, a long muscle capable of drawing up the third stomach, so as to receive alimentary matters directly from the gullet, when the immediate wants of the animal are to be supplied; but when the fluid taken is meant to be used only in its long journeys through the deserts, this muscle is relaxed, and it is thus received into the two first stomachs, and transmitted onwards by these only at the necessary intervals. The Arabs who traverse these extensive plains, accompanied by these useful animals, are, it is said, sometimes obliged, when faint and in danger of perishing from thirst, to kill one of their camels, for the sake of the water contained in these reservoirs, which is always found pure and wholesome. It is stated by those who have travelled in Egypt, that camels, when accustomed to go journeys during which they are for a long time deprived of water, acquire the power of dilating the cells, so as to make them contain a more than ordinary quantity, as a supply for their journey.

COMPENSATION OF PARTS IN ANIMATED NATURE.

The evidences of design in creation are beautifully developed in what is called the compensatory structure of animals. By this is signified the supplying the defects of one organ by the structure of another part or organ. Paley has summed up a few striking instances of this nature. "The short unbending neck of the elephant (says he) is compensated by the length and flexibility of his *proboscis*. He could not have reached the ground without it; or, if it be supposed that he might have fed upon the fruit, leaves, or branches of trees, how was he to drink? Should it be asked, Why is the elephant's neck so short? it may be answered, that the weight of a head so heavy could not have been supported at the end of a longer lever. To a form, therefore, in some respects necessary, but in some respects also inadequate to the occasions of the animal, a supplement is added, which exactly makes up the deficiency under which he laboured.

If it be suggested that this *proboscis* may have been produced, in a long course of generations, by the constant endeavour of the elephant to thrust out his nose (which is the general hypothesis by which it has lately been attempted to account for the forms of animated nature), I would ask, How was the animal to subsist in the meantime, during the process, *until* this prolongation of snout were completed? What was to become of the individual whilst the species was perfecting?

Our business at present is simply to point out the relation which this organ bears to the peculiar figure of the animal to which it belongs. And herein all things

correspond. The necessity of the elephant's proboscis arises from the shortness of his neck; the shortness of the neck is rendered necessary by the weight of the head. Were we to enter into an examination of the structure and anatomy of the proboscis itself, we should see in it one of the most curious of all examples of animal mechanism. The disposition of the ringlets and fibres, for the purpose, first, of forming a long cartilaginous pipe; secondly, of contracting and lengthening that pipe; thirdly, of turning it in every direction at the will of the animal; with the superaddition, at the end, of a fleshy production of about the length and thickness of a finger, and performing the office of a finger, so as to pick up a straw from the ground—these properties of the same organ taken together, exhibit a specimen not only of design (which is attested by the advantage), but of consummate art, and, as I may say, of elaborate preparation, in accomplishing that design.

The hook in the wing of a *bat* is strictly a mechanical, and also a *compensating*, contrivance. At the angle of its wing there is a bent claw, exactly in the form of a hook, by which the bat attaches itself to the sides of rocks, caves, and buildings, laying hold of crevices, joinings, chinks, and roughnesses. It hooks itself by this claw; remains suspended by this hold; takes its flight from this position: which operations compensate for the decrepitude of its legs and feet. Without her hook, the bat would be the most helpless of all animals. She can neither run upon her feet, nor raise herself from the ground. These inequalities are made up to her by the contrivance in her wing; and in placing a claw on that part, the Creator has deviated from the analogy observed in winged animals. A singular defect required a singular substitute.

The *crane* kind are to live and seek their food amongst the waters, yet, having no web feet, are incapable of swimming. To make up for this deficiency, they are furnished with long legs for wading, or long bills for groping; or usually with both. This is *compensation*. But I think the true reflection upon the present instance is, how every part of nature is tenanted by appropriate inhabitants. Not only is the surface of deep waters peopled by numerous tribes of birds that swim, but marshes and shallow pools are furnished with hardly less numerous tribes of birds that wade.

The common *parrot* has, in the structure of its beak, both an inconvenience and a *compensation* for it. When I speak of an inconvenience, I have a view to a dilemma which frequently occurs in the works of nature, viz., that the peculiarity of structure by which an organ is made to answer one purpose, necessarily unfits it for some other purpose. This is the case before us. The upper bill of the parrot is so much hooked, and so much overlaps the lower, that if, as in other birds, the lower chap alone had motion, the bird could scarcely gape wide enough to receive its food; yet this hook and overlapping of the bill could not be spared, for it forms the very instrument by which the bird climbs; to say nothing of the use which it makes of it in breaking nuts and the hard substances upon which it feeds. How, therefore, has nature provided for the opening of this occluded mouth? By making the upper chap moveable, as well as the lower. In most birds the upper chap is connected, and makes but one piece, with the skull; but in the parrot, the upper chap is joined to the bone of the head by a strong membrane placed on each side of it, which lifts and depresses it at pleasure.

The *spider's web* is a *compensating* contrivance. The spider lives upon flies, without wings to pursue them; a case, one would have thought, of great difficulty, yet provided for, and provided for by a resource which no stratagem, no effort of the animal, could have produced, had not both its external and internal structure been specifically adapted to the operation.

In many species of insects the eye is fixed, and consequently without the power of turning the pupil to the object. This great defect is, however, perfectly *compensated*, and by a mechanism which we should not

suspect. The eye is a multiplying glass, with a lens looking in every direction, and catching every object; by which means, although the orb of the eye be stationary, the field of vision is as ample as that of other animals, and is commanded on every side. When this lattice-work was first observed, the multiplicity and minuteness of the surfaces must have added to the surprise of the discovery. Adams tells us that fourteen hundred of these reticulations have been counted in the two eyes of a drone-bee.

In other cases the *compensation* is effected by the number and position of the eyes themselves. The spider has eight eyes, mounted upon different parts of the head; two in front, two in the top of the head, two on each side. These eyes are without motion, but by their situation suited to comprehend every view which the wants or safety of the animal render it necessary for it to take.

The Memoirs for the Natural History of Animals, published by the French Academy in the year 1687, furnish us with some curious particulars in the eye of a chameleon. Instead of two eyelids, it is covered by an eyelid with a hole in it. This singular structure appears to be *compensatory*, and to answer to some other singularities in the shape of the animal. The neck of the chameleon is inflexible. To make up for this, the eye is so prominent, that more than half of the ball stands out of the head; by means of which extraordinary projection, the pupil of the eye can be carried by the muscles in every direction, and is capable of being pointed towards every object. But, then, so unusual an exposure of the globe of the eye requires, for its lubricity and defence, a more than ordinary protection of eyelid, as well as a more than ordinary supply of moisture; yet the motion of an eyelid, formed according to the common construction, would be impeded, as it should seem, by the convexity of the organ. The aperture in the lid meets this difficulty. It enables the animal to keep the principal part of the surface of the eye under cover, and to preserve it in a due state of humidity without shutting out the light; or without performing every moment a nictitation, which, it is probable, would be more laborious to this animal than to others.

But the works of the Deity are known by expedients. Where we should look for absolute destitution, where we can reckon up nothing but wants, some contrivance always comes in to supply the privation. A *snail*, without wings, feet, or thread, climbs up the stalks of plants, by the sole aid of a viscid humour discharged from her skin. She adheres to the stems, leaves, and fruits of plants, by means of a sticking plaster. A *mussel*, which might seem, by its helplessness, to lie at the mercy of every wave that went over it, has the singular power of spinning strong tendinous threads, by which she moors her shell to rocks and timbers. A *cockle*, on the contrary, by means of its stiff tongue, works for itself a shelter in the sand. The provisions of nature extend to cases the most desperate. A *lobster* has in its constitution a difficulty so great, that one could hardly conjecture beforehand how nature could dispose of it. In most animals, the skin grows with their growth. If, instead of a soft skin, there be a shell, still it admits of a gradual enlargement. If the shell, as in the tortoise, consists of several pieces, the accession of substance is made at the sutures. Bivalve shells grow bigger by receiving an accretion at their edge; it is the same with spiral shells at their mouth. The simplicity of their form admits of this. But the lobster's shell being applied to the limbs of the body, as well as to the body itself, allows not of either of the modes of growth which are observed to take place in other shells. Its hardness resists expansion, and its complexity renders it incapable of increasing its size by addition of substance to its edge. How, then, was the growth of the lobster to be provided for? Was room to be made for it in the old shell, or was it to be successively fitted with new ones? If a change of shell became necessary, how was the lobster to extricate himself from his present con-

finement? how was he to uncase his buckler, or draw his legs out of his boots? The process which fishermen have observed to take place, is as follows:—At certain seasons, the shell of the lobster grows soft; the animal swells its body; the seams open, and the claws burst at the joints. When the shell has thus become loose upon the body, the animal makes a second effort, and by a tremulous spasmodic motion, casts it off. In this state, the liberated but defenceless fish retires into holes in the rock. The released body now suddenly pushes its growth. In about eight-and-forty hours, a fresh concretion of humour upon the surface, *i. e.* a new shell, is formed, adapted in every part to the increased dimensions of the animal. This wonderful mutation is repeated every year."

In the changing of the colour of the chameleon, we see one of the beautiful compensatory provisions of nature. This little animal, which is common in the East Indies and some other Asiatic countries, lives upon flies, beetles, or other insects, which it catches by climbing up shrubs or trees, and darting out its tongue; but its pace is slow, and as insects have good eyes to perceive the approach of an enemy, they would be sure to make their escape in the present case, unless the chameleon approached them in disguise. This, therefore, it invariably does. As it passes among green leaves, it is of a green colour; and when it glides by any of a red or yellow tinge, so does it change its hue to red or yellow. So closely does it assume not only the shades and colours, but even the shapes of the leaves around, that a spectator might look at the tree for some minutes before discovering it. How wisely, therefore, has the Creator endowed this poor reptile with the wonderful gift of altering the colour of its skin; for if it were not possessed of such a property, it would inevitably die of hunger.

By carrying our observation upward from the mere physical organisation of man, to the *mind* which he possesses, and is able to exert in reference to both sensible objects and abstract subjects, we have still greater reason to admire the proofs of design and goodness in an overruling Creator; for we all feel that this principle of mind—how constituted we do not here stop to inquire—is in harmony with the other works of creation around us. For example, how much are our minds suited to the recognition of what is beautiful in nature and art. This, however, admits of a few separate observations.

BEAUTY.

The wisdom of the great original Contriver is eminently manifested in that property of inanimate and animate objects which we call beauty. Here there is an evident fitness between the taste and habits of animals, human beings included, and what can be seen by the eye. We feel pleasure in contemplating the works of nature most obvious to our senses; and we cannot but remark, that that which is loathsome is not ordinarily presented to the eye. The splendid colouring of the vegetable kingdom, the smooth or spotted skins of the brute creation, and the lovely plumage of the feathered tribe, all give us delight in the contemplation. Consider, also, how beautiful is the outward appearance of the human form. Reflect on what the parts and materials are of which the fairest body is composed, and no further observation will be necessary to show how well these things are wrapped up, so as to form a mass which will be capable of symmetry in its proportion, and of beauty in its aspect; how the bones are covered—the bowels concealed—the roughness of the muscle smoothed and softened; how over the whole is drawn an integument, the skin, which converts the disgusting materials of a dissecting-room into an object of attraction to the sight, or one upon which it rests at least with ease and satisfaction.

The more minutely that we inspect the works of nature, the greater cause have we to wonder at the extraordinary perfection and beauty every where prevalent. The microscope develops splendours in the

creation of insects which we can hardly comprehend. The back of a diamond-beetle exhibits an assemblage of brilliant colours and glittering gems more splendid than any artificial arrangement of the most precious stones. The colours of the feathers of birds in tropical climates, and the skins of the fishes of Ceylon, are incomparable for their beauty. And why is all this the case? Because it yields a pleasure to the sight, both of men and other living creatures; for the Creator has not denied the feeling of delight to the meanest reptile which crawls. All is beautiful, it would appear, in the estimation of one or other of living creatures. The most insignificant little flower, now blooming far from the haunts of men, in some remote wilderness, does not, as has been said, waste its sweetness on the desert air. It furnishes an object of pleasing gratification to some description of sentient creatures, perhaps so small as to be imperceptible to our naked eye.

Placing agreeableness of aspect entirely out of the question, there is another purpose answered by the skin, and that is concealment. Were it possible to view through this integument the mechanism of our bodies, the sight would frighten as much as it would disgust us. Durst we make a single movement, or stir a step from the place we were in, if we saw our blood circulating, the tendons pulling, the lungs blowing, the humours filtrating, and all the incomprehensible assemblage of fibres, tubes, pumps, valves, currents, pivots, which sustain an existence at once so frail and so presumptuous?

In clothing the human frame with a covering of skin, the Creator has not omitted to vary its character according to local necessities. The skin is most beautiful on the face, because the face is most exposed to observation; it is softest where least liable to injury, and hardest or firmest in texture where it is most subject to be pressed upon. There is not less sign of contrivance in the manner in which it ceases at the extremities of the toes and fingers. A man has only to look at his hand, to observe with what nicety and precision that covering, which extends over every other part, is here superseded by a different substance and a different texture. Why do we find the skin cease at our fingers' ends, or on the back part of the fingers, and not the fore part? Because something hard or horny was required on these parts, by which we could hold fast or lift nimbly objects which we wished to grasp or seize upon. Nails therefore supersede the skin on such places. The same forethought is visible in the covering of our heads. What could have been a more beautiful or appropriate substance wherewith to cover the head and preserve the hard bony skull from injury, than the hair, a substance at once light, warm, and graceful?

DESIGN IN VEGETABLE PHYSIOLOGY.

In accordance with our intentions of glancing through most of the natural sciences, and bringing home to the main object of our labours treasures illustrative of design from them all, let us now turn our attention to those afforded by the vegetable kingdom of nature. And first, of the mutual relations that exist between animals and vegetables; in considering which, we shall find that these two great organised kingdoms of the creation are made to co-operate in the execution of the same design; each ministering to the other, and preserving that due balance in the constitution of the atmosphere, which adapts it to the welfare and activity of every order of beings, and which would soon be destroyed were the operations of any one of them to be suspended. "It is impossible to contemplate so special an adjustment of opposite effects, without admiring this beautiful dispensation of Providence, extending over so vast a scale of being, and demonstrating the unity of plan on which the whole system of organised creation has been devised." We said in a former part of this essay, that two principles of atmospheric air were oxygen and carbon; that the former was as essential to animal life as the latter was obnoxious to it; but that, on the other hand, carbon was indispensable to the continuance of

vegetable organisations. We will now endeavour to explain this by a short account of the phenomena of respiration as displayed in the two kingdoms. Among animals, the function of respiration is that by which the blood, received into its vessels from the alimentary canal, is, during its subsequent circulation, kept in a state of requisite purity. This is in all cases effected by bringing it, at intervals, into contiguity, either with atmospheric air alone, or with water containing this air diffused through it; when such is the mutual action of the blood and the air upon each other, that the former is purified, and passes in general from a dingy purple to a bright scarlet colour, while the latter is in the same degree rendered impure, and after a time becomes inadequate to support either respiration or combustion. Now, whether the ærating organs be lungs or gills, it appears to be the object of nature, in their construction, to expose a large surface to the contact of air. This object is accomplished by their division into numerous cells or leaf-like processes, or by their extension on the walls of cavities, or the surface of pectinated ridges. The blood brought to these organs is there distributed by their terminating branches. Although still retained in vessels, it can nevertheless be easily acted upon by the air on the exterior. Priestley found the colour of blood changed by the air when enclosed in a moistened bladder, and the same effect was observed by Hunter when it was covered with goldbeaters' skin. It is scarcely possible to determine by direct observation what is the exact nature of the changes that the blood undergoes in its passage through the lungs; the most obvious is its change of colour; and the chemical differences between the dark purple blood in the veins before it has reached the lungs, and the bright vermilion colour it exhibits in the arteries after it has circulated through the lungs, and been exposed to the influence of the air, may be collected from the changes made in the air itself. Atmospheric air is known to consist of certain principles in definite proportions; when it has acted upon the blood, and is returned from the lungs, it is found that a certain proportion of oxygen which it contained has disappeared, and that the place of this oxygen is almost wholly supplied by an addition of carbonic acid gas and watery vapour. The exact quantity of oxygen which is lost in natural respiration, varies in different animals, and even in different conditions of the same animal. Birds, for instance, consume larger quantities of oxygen by their respiration, and hence require, for the maintenance of life, a purer air than other vertebrated animals. Vauquelin, however, found that many species of insects and worms possess the power of abstracting oxygen from the atmosphere in a much greater degree than the larger animals; thus, snails are capable of living for a long time in the vitiated air in which a bird had perished. Some insects which conceal themselves in holes, or burrow under ground, have been known to deprive the air of every appreciable portion of its oxygen. It is observed by Spallanzani, that those animals whose modes of life oblige them to remain for a great length of time in these confined situations, possess this power in a greater degree than others which enjoy more liberty of moving in the open air: so admirably have the faculties of animals been, in every instance, accommodated to their respective wants.

Now, bearing in mind that the air coming in contact with the blood of animals parts with its oxygen, and receives in its place carbonic acid gas, let us consider the function of respiration, or more properly æration, as it occurs in vegetables. It was necessary that some means should be appointed by which this great quantity of carbon given out into the air by animals, and so injurious to animal life, should be removed from it. We have said that this principle was necessary to vegetable life; and here we find the means not only by which in a very considerable degree it is procured, but also by which it is removed from the atmosphere. The leaves of plants are analogous to the lungs of animals, and it is in them principally that the decomposition of the carbonic

acid absorbed from the air is effected. When exposed to the action of the sun, they decompose that gas, retain its carbon, and disengage its oxygen. Solar light is an essential agent in effecting this chemical change; for it is never found to take place at night, nor while the plant is kept in the dark. That the carbon resulting from this decomposition of carbonic acid is retained by the plant, has been most satisfactorily proved by the experiments of Saussure, who found that this process is attended with a sensible increase in the quantity of carbon which the plant had previously contained. "Thus the great object to be answered by this vegetable æration," says Dr Roget, speaking at considerable length of this undeniable evidence of design to which we have thus shortly alluded, "is exactly the converse of that which we see effected by the respiration of animals; in the former, it is adding carbon to the vegetable organisation; in the latter, it is that of discharging the superfluous quantity of carbon from the animal system. On the whole, therefore, the atmosphere is continually receiving from the vegetable kingdom a large accession of oxygen, and is at the same time freed from an equal portion of carbonic acid gas, both of which effects tend to its purification, and to its remaining adapted to the respiration of animals."

We have not much space to devote to the contemplation of vegetables, but we are unwilling to leave the subject without alluding to some other evidences of design which we find displayed in them. Among these, nothing more beautifully demonstrates that nature, or rather the Almighty Creator of nature, proceeds on a uniformity of plan and design, than the fact that plants as well as animals are possessed of the means of reproducing and continuing their species. The pistil which occupies the centre of the flower is destined to produce the seeds, while the stamens of the plant contain the dust necessary for fertilising them, and without which the seeds would not produce young plants. Nature has guarded with nice care this precious dust, for on its preservation depends the continuance of the species. The apparatus by which in many flowers it is defended from injury, is very curious; nor are the means that are provided by which it comes in contact with the stigma of the pistil less demonstrative of a great, a wise, and a beneficent Providence. In some plants where the organs are in the same flower, the stamens are placed above the stigma, upon which the dust, or pollen, falls by its own gravity; in others, we find the contrary is the case, the pistil being the longest; but here the flower is generally drooping. To assist the emission of the pollen, and its contact with the stigma, in many plants the stamens possess a very apparent moving power. When ripe, the ten stamens of the rue are seen alternately to bend down upon the stigma, deposit their portion of pollen, and return to their former position. The stalks or filaments of the peltitory of the wall are possessed of a remarkable elasticity, and thus forcibly scatter the pollen. This is very apparent if touched by the point of a needle; immediately it acts with a jerk, which dashes the pollen with some force on the stigma. The same arrangement is met with in the barberry bush, in which the six stamens remain sheltered under the concave tips of the flower-leaves or petals, till some extraneous body, as an insect in search of honey, touches the filament, which instantly contracts, and also dashes the pollen against the stigma. But all plants have not their stamens and pistils sheltered under the same veil; in many they are in different flowers, and in others even placed on different plants. Here, again, we have to admire the wise measures nature has taken for the accomplishment of her designs. In many the scattering of the pollen is effected by the winds; to favour the access of which, we find in some, as the hazel, the leaves are not evolved until after the seed has been perfected; or, if the plants be evergreens, the leaves are needle-shaped, so as to present very little obstacle to the passage of the pollen, which is secreted in much larger quantity than usual. Various species of insects, and especially the bee, are selected by nature for this pur-

pose. In the pink we observe numerous small insects creeping to and fro, and thus depositing the pollen on the stigma. In flowers where the stamens and pistils are on different plants, often at a considerable distance from each other, bees, and other flying insects, are peculiarly accessory to the great end of nature. These insects, it is true, do not visit the flower for the purpose of scattering the pollen; they only seek for the sweet juice which exudes from its nectary. Their hairy body, which nature did not bestow without design, is seen covered with pollen, often in such quantities as to impede the progress of the animal; this, whenever they visit another flower, is rubbed against the stigma; and it is a fact, no less wonderful than calculated to fill us with admiration at the wise provision of nature, that many insects are peculiar to one flower, and that others, as the bee, will only visit one species in each journey from its hive.

The various methods which nature employs to disperse the different varieties of seeds over the earth, are truly wonderful. Many plants, when the seed is fully ripe, discharge it from its covering, with a jerk or elastic spring. The common oat is thrown out in this way; and the loud crackling of the pods of the broom in a dry sunny day, or, as Drummond has it, "bursting seed-balls crackling in the sun," is caused by their bursting and scattering about the contained seeds, and must have been frequently noticed. "Who has not listened," again asks Sir James Edward Smith, "in a calm and sunny day, to the crackling of the furze bushes, caused by the explosion of their elastic little pods; or watched the down of innumerable seeds floating on a summer breeze, till they are overtaken by a shower, which, moistening their wings, stops their farther flight, and at the same time accomplishes its final purpose, by immediately promoting the germination of each seed in the moist earth! How little are children aware, when they blow away the seeds of the dandelion, or stick burs in sport upon each other's clothes, that they are fulfilling one of the great ends of nature!" These downy appendages to which Sir J. E. Smith alludes, buoy up the lighter seeds, as the thistles, and carry them floating through the air to great distances. Then there are the currents of rivers which bear the seeds from one part of the country to another; and even seas and oceans, whose tides and currents float along the germs of vegetation to the various regions of the globe. Birds, too, by feeding on particular seeds, carry them to great distances, where, being often voided entire, they vegetate. There is evident design in this. It could not have been by mere chance, that in flowers which stand erect, the pistil is shorter than the stamens, permitting the pollen as it falls to descend upon the stigma; and when the flower is drooping, that the contrary arrangement is effected. And surely no one will be blind or hardy enough to assert that the mechanical means, to which we have alluded, for the dispersion of seeds, with all the beauty and aptitude of its arrangement, was not the result of divine wisdom—a wisdom which will be still more apparent when we extend our views from the power which called into being such various and beauteous existences, and gave the means of distributing them over the globe, and consider the laws that govern that distribution which we so much admire.

It is not here out of place to remark, that there is scarcely a vegetable production on which some species of animal does not subsist; and, generally speaking, wherever that peculiar production is to be found, there also is the animal to which it furnishes wholesome food. With some striking examples of this kind, the most uneducated man is acquainted; he knows that the partridge is on the plain, the woodcock in the forests, the grouse on the moors, and the ptarmigan on the loftiest peaks of the mountains. He knows, too, that other species migrate from country to country, seeking their food in distant regions, over trackless oceans, when it falls in their native haunts; and among the animal kingdom so universal is this, as to form an example of

the wonderful adaptations which exist between it and the vegetable world. Vegetables, like animals, are adapted to varieties of climate and temperature; and when we consider their distribution over the globe, we shall find that those which are most essential to the maintenance of man, bear a variety of climate better than most others. This is the case with greens, carrots, potatoes, and many kinds of grain. Warm climates are much more favourable to vegetation than cold. In Spitzbergen, the whole number of plants with conspicuous flowers, natives of the country, is found by botanists scarcely to exceed thirty species; while in the warmer regions of the West Indies, in Madagascar and the coast of Coromandel, Willdenow enumerates from four to five thousand different species of indigenous plants. Now, observe how admirably this distribution of plants corresponds with the wants and necessities of man. A vegetable diet is most suitable both to the tastes and the actual needs of the inhabitants of warm climates, and there we find that kind of food most abundant.

It is impossible for a reflecting individual to walk beside a field of growing barley, without being impressed with the conviction, that, in the economy of this description of grain, the design of a Creator has been wonderfully manifested. An ear of barley differs from one of wheat or oats. Each of the grains is furnished with a long slender bristle or beard, which is prickly to the touch, and seems to serve as a protection to the ear. These bristles form a roof, if we may so call it, to carry off the rain from the ear, and yet, by their elegant disposition, do not prevent the heat of the sun and the light from influencing the grain. And why should such be the case with barley, when the ears of wheat, oats, &c., do not possess any such protective process? Because barley is a grain easily injured by wet, which if not carried off, would cause the ear to sprout even while on the stalk, and consequently be entirely useless to man.

In speaking of the economy of vegetable life, it should not pass unnoticed that there is a remarkable instance of creative wisdom in the means which have been arranged for the growth of plants from putrescent matter. All kinds of vegetable and animal substances, when deprived of life, as well as excrementitious matter, have a tendency to decomposition—that is, to resolve themselves into those elementary gases of which they have been chiefly composed. This process of dissolution, as every one knows, produces a most disagreeable odour, which is often inimical to animal life. But this is not an evil; it displays a bountiful provision in nature; for it tells us, in a way not to be misunderstood, that the substance undergoing, or about to undergo, the putriferactive process, should be buried underground; and being there deposited, it immediately proceeds to supply its no longer useful gases to the infant plants and crops of grain which flourish on the surface. Thus do we see another striking evidence of the harmonious design which every where prevails between the animal and vegetable creation.

It has been said that a vegetable diet is preferred by the inhabitants of warm countries: to them sobriety is an easy virtue and a happy consequence of the climate. The people of northern regions, on the contrary, are voracious from instinct and necessity. They swallow enormous quantities of food, and prefer those substances which in digestion produce the most heat. Obligated to struggle incessantly against the action of cold, their life is but a continual act of resistance to external influences. Let us not reproach them with voracity, and their avidity for ardent spirits and fermented liquors. Those nations which inhabit the confines of the habitable world, in which man is scarcely able to withstand the severity of the climate, the inhabitants of Kamtschatka, the Samoiedo, &c., live on fish, that, in the heaps in which they are piled up, have already undergone a certain degree of putriferactive fermentation. In them there is a necessity for this inward excitement, which in our climate would be inevitably

attended with disease, and probably death. The abuse of spirituous liquors is fatal to the European transported to the burning climate of the West Indies. The Russian drinks spirituous liquors with a sort of impunity, and lives on to an advanced age, amidst excesses under which an inhabitant of the south of Europe would sink.

The influence of climate not only affects alike the regimen of man in health, but of man in sickness; and it has been justly observed of medicine, that it ought to vary according to the places in which it is practised. A few substances, for the most part obtained from the vegetable kingdom, sufficed to Hippocrates in the treatment of diseases; and physicians who practise in a climate such as Greece, may imitate the simplicity of the father of medicine. Opium, bark, wine, spirits, aromatics, and the most powerful cordials, are, on the other hand, the medicines suited to the inhabitants of the north; and thus we are enabled to use freely those medicines which elsewhere would be attended with the utmost danger.

We are now prepared to understand the beautiful and wonderful harmony that exists between the distribution of man and plants over the globe; and no one, we think, can deny their meed of praise and admiration for the care and beneficence which this universal adaptation exhibits.

The frigid zone contains but few species of plants, and the verdure of those countries which lie within the polar circle is confined chiefly to the hills having a southern aspect, and the trees are of very diminutive growth. Besides mosses and lichens, there exist ferns, creeping plants, and some shrubs yielding berries of an agreeable flavour. The arctic regions of Europe are peculiarly favoured; for in certain parts of Lapland there are fine forests, and even rye and leguminous plants are produced.

In the high latitudes of the northern temperate zone are the pine and the fir, which show their adaptation to a cold climate by retaining their verdure in the midst of the regions of winter. To these, as advancing southward, succeed the oak, the elm, the beech, the lime, and other forest-trees. Several fruit-trees, among which are the apple, the pear, the cherry, and the plum, grow better in the northern half of this zone; while to its more southern parts, especially, belong the more delicate fruits, such as the olive, the lemon, the orange, and the fig, and, among trees, the cedar, the cypress, and the cork.

The space comprised between the 30th and the 50th parallels of latitude may be considered as the country of the vine and the mulberry. Wheat extends as far north as the 60th degree; oats and barley a few degrees farther. In the southern parts of this zone, maize and rice are more commonly cultivated.

The vegetation of the torrid zone is characterised by a wealth, a variety, and a magnificence, which are nowhere to be found in the regions of the globe. Under the beams of a tropical sun, the most juicy fruits arrive at perfection; and innumerable productions supply the wants and administer to the luxuries of man. There the grounds yield the sugar-cane, the coffee-tree, the palm, the bread-tree, the pisang, the immense baobab, the date, the cocoa, the vanilla, the cinnamon, the nutmeg, the pepper, the camphor, and numerous other fruits and aromatics. In South America is the remarkable tree called the *cow-tree*, which, when incisions are made in its trunk, yields abundance of a glutinous and nourishing milk.

CONCLUSION.

But we must hasten to conclude our interesting subject. Illustrations of design might be produced from the works of nature without end; every link in the chain of creation teems with proofs of it; in none can any one affirm with truth that it is wanting. Cursory as our remarks have been, they still must lead to the general conclusion that not only design, but unity of design and identity of operation, pervade the works of

nature, in as far as relates to organised existences; and even among those portions of creation which are not organic, there do we find the same evident desire and design to render them subservient to the wants and necessities of those which are. To several of these we have alluded, though it did not accord with our plan to allude to all; and we need only further draw attention to the remarkable uniformity in the plan of creation. The universe itself is a system; each part depending upon other parts, or being connected with other parts by some common law of motion, or by the presence of some common substance. One principle of gravitation causes a stone to drop towards the earth, and the moon to wheel round it. One law of attraction carries all the different planets round the sun. New countries are continually discovered, but the old laws of nature are always found in them—new plants, perhaps, or animals, but always in company with plants and animals which we already know, and always possessing many of the same general properties. We never get amongst such original or totally different modes of existence, as to indicate that we are come into the province of a new Creator, or under the direction of a different will. In truth, the same order of things attends us wherever we go. There is every where a perfect uniformity in the laws which regulate the phenomena of nature. And this very fact, while forcibly illustrating the unity of that power by whose instrumentality all that we see was ordered and originated, demonstrates most strikingly, at the same time, the surpassing wisdom of the same creative being. What agency, but one endowed with omniscience, could have educed results so mighty from a few simple and uniform laws?—could have instituted and set in action these laws at the first, assured that, without change, or shadow of change, they would fulfil to the last all the great objects connected with the progressive development of the scheme of the universe! Thus, all that we behold around us, all that we can learn of nature, impresses us with a sense at once of the unity and greatness of the creative being. If these pages have tended to strengthen that conviction, they have attained their object. We cannot close them more fitly, perhaps, than by extracting a few lines from the powerful summing-up by the poet Young, of the arguments on this very subject.

“What am I? and from whence?—I nothing know,
But that I am: and since I am, conclude
Something eternal: had there e'er been nought,
Nought still had been: eternal there must be.
But what eternal?—Why not human race?
And Adam's ancestors without an end?
That's hard to be conceiv'd. Yet grant it true,
Whence earth and these bright orbs?—Eternal too?
Grant matter was eternal, still these orbs
Would want some other father;—much design
Is seen in all their motions, all their makes:
Design implies intelligence, and art;
That can't be from themselves, or man: that art
Man scarce can comprehend, could man bestow?
Who motion, foreign to the smallest grain,
Shot through vast masses of enormous weight?
Who bade brute matter's restive lump assume
Such various forms, and gave it wings to fly?
Has matter innate motion? then each atom,
Asserting its indisputable right
To dance, would form an universe of dust:
Has matter none? Then whence these glorious forms
And boundless flights, from shapeless, and repos'd?
Has matter more than motion?—has it thought,
Judgment, and genius?—is it deeply learn'd
In mathematics? Has it fram'd such laws,
Which but to guess a Newton made immortal?—
If so, how each sage atom laughs at me,
Who think a clod inferior to a man!
If art to form, and counsel to conduct,
And that with greater far than human skill,
Resides not in each block—a Godhead reigns—
And if a God there is, that God how great!”

HISTORY OF THE BIBLE—CHRISTIANITY.

Paul preaching at Athens.

OLD TESTAMENT.

THE Bible is the most remarkable work now in existence. In the libraries of the learned there are frequently seen books of an extraordinary antiquity, and curious and interesting from the nature of their contents; but none approach the Bible, taken in its complete sense, in point of age, while certainly no production whatever has any pretension to rival it in the dignity of composition, or the important nature of the subjects treated of in its pages. The word *Bible* is of Greek origin, and, in signifying simply *the Book*, is expressive of its superiority over all other literary productions. The origin and nature of this every way singular work—how it was preserved during the most remote ages, and how it became known to the modern world in its present shape—form a highly interesting chapter of literary history.

The Bible comprehends the foundation of the religious belief of the Jews and Christians, and is divided into two distinct portions, entitled the Old and New Testament, the former being that which is esteemed by the Jewish nation, but both being essential in forming the faith of the Christian. The Old Testament is the largest department of the work, and appears a collection of detached histories, moral essays, and pious poetical compositions, all placed together in the order of time, or as they may serve for the purpose of mutual illustration. On taking a glance at the contents, the principal subject of narration seems to be the history of the Jews, commencing with an account of the creation of the world, and tracing their history, genealogically, through a series of striking vicissitudes and changes of situation. But when we examine the narratives minutely, it is found that there is another meaning than that of mere historical elucidation. It is perceived

that the whole train of events recorded, the whole of those lofty impassioned strains of poetry which distinguish the volume, are precursory and prophetic of a great change which, at a future period, was to be wrought on the moral character and fate of mankind, by the coming to the earth of a Messiah.

The authorship of the Old Testament has been universally ascribed, by both Jews and Christians, to pious men who were inspired or influenced by God to communicate to the world a correct knowledge of the foundations of religious belief and moral obligation. The Bible is hence called the Revealed Word of God, or the Sacred Scriptures. "We are to look to the Word of God, then (says an able writer), as contained in the Scriptures of the Old and New Testaments, for the only sure rule of faith and practice. But there is this singularity in the Sacred Scriptures, that we do not find in them a set treatise on any one of the interesting subjects which engage our attention as moral and religious beings. No attempt is made to prove the existence of a God; such an attempt would have been entirely useless, because the fact is universally admitted. The error of men consisted not in denying a God, but in admitting too many; and one great object of Scripture is to demonstrate that there is but one. No metaphysical arguments, however, are employed for this purpose. The proof rests on facts recorded in the history of the Jews, from which it appears that they were always victorious and prosperous so long as they served Jehovah, the name by which the Almighty made himself known to them; and uniformly unsuccessful, when they revolted from him to serve other gods. What argument could be so effectual to convince them that there was no God in all the earth but the God of Israel? The sovereignty and universal providence of the Lord Jehovah, are proved by predictions delivered by the Jewish prophets, pointing out the fate of nations and of empires, specifying distinctly the cause of their rise, the duration of their power, and the reason of their decline; thus demonstrating that *one* God ruled among the nations, and made them the unconscious instruments of promoting the purposes of his will.

The writers, generally speaking, do not reason, but exhort and remonstrate; they do not attempt to fetter the judgment by the subtleties of argument, but to rouse the feelings by an appeal to palpable facts. But though there is no regular treatise in the Scriptures on any one branch of religious doctrine, yet all the materials of a regular system are there. The word of God contains the doctrines of religion in the same way as the system of nature contains the elements of physical science. In both cases, the doctrines are deduced from facts, which are not presented to us in any regular order, and which must be separated and classified before we can arrive at first principles, or attain to the certainty of knowledge; and in both cases, a consistent system can only be made out by induction and investigation. The very circumstance of no detailed system

being given, renders it necessary to form one; for although a portion of religious and physical knowledge sufficient for the common purposes of life, may be obtained by traditional information, and men may work conveniently enough by rules without possessing much general knowledge; yet they who would teach with profit, must generalise, and they who would explain the ways of God, must arrange the materials which are so amply furnished, but which are presented apparently without order or plan.*

The periods when the act of writing all or greater part of the Scriptures took place, as well as most of the names of those who were instrumental in forming the work, have been ascertained with considerable accuracy, both from written evidence in the narratives themselves, and from the well-preserved traditions of the Jews. Generally speaking, it cannot be said that the books of the Old Testament are of a less antiquity than from two thousand three hundred to four thousand years—an antiquity considerably greater than that of any profane history. At whatever time, however, the different books were written, they were not collected from the sacred depositories of the Jews, where they had been carefully placed, till long after their immediate authors were deceased; and their present arrangement, as we shall afterwards explain, is of comparatively modern date.

From an early period, it was the custom of the Jews to divide the books of the Old Testament into three classes, which they respectively designated the *Law*, the *Prophets*, and the *Hagiographa*, or *Holy Writings*, which last division includes more particularly the *poetical parts*; and some are of opinion that Jesus Christ alludes to this division of the scriptures, when he says that "all things must be fulfilled that were written in the *Law of Moses*, and in the *Prophets*, and in the *Psalms*, concerning him." For by the book of *Psalms* they understand all the books of the third class. The *Law* comprehends the *Pentateuch*, that is, *Genesis*, *Exodus*, *Leviticus*, *Numbers*, and *Deuteronomy*—such including both an historical narrative, and the injunctions forming the legal code of the Jews. The prophetic books are eight: namely, 1. *Joshua*; 2. *Judges*, with *Ruth*; 3. *Samuel*; 4. *Kings*; 5. *Isaiah*; 6. *Jeremiah*; 7. *Ezekiel*; and 8. the *twelve Lesser Prophets*. The first four books of this division are called the *Former Prophets*, and the last four the *Latter Prophets*. The *Hagiographa*, or *Holy Writings*, are nine; namely, 1. *Job*; 2. the *Psalms*; 3. the *Proverbs*; 4. *Ecclesiastes*; 5. the *Song of Songs*; 6. *Daniel*; 7. *Chronicles*; 8. *Ezra*, with *Nehemiah*; and 9. *Esther*.

According to the order in which the books of the Old Testament now stand, those of an historical nature are appropriately placed at the beginning. The first five books, having a chain of connexion throughout, are *Genesis*, *Exodus*, *Leviticus*, *Numbers*, and *Deuteronomy*. These are styled the *Pentateuch*, such being the Greek compound for *five books*. They are likewise entitled the *Books of Moses*, from the belief that that enlightened Jewish leader composed them.

The Jews, or Hebrews, take the name of the sacred books from the first word with which each begins; but the Greeks, whom our translators generally follow, take the names from the subject-matter of them. Thus, the first book is called by the Hebrews *Bereshith*, which signifies *In the beginning*, these being the first words; but the Greeks call it *Genesis*, which signifies *Production*, because the creation of the world is the first thing of which it gives an account. It likewise contains an account of the increase of mankind; of their corruption of manners, and its cause; of their punishment by the Deluge; of the origin of the Jewish people from Abraham; of the manner in which God was pleased to have them governed; and, particularly, of the nature of the special superintendence vouchsafed to the Jewish nation by the Creator. This comprehensive narrative reaches from the creation of the world till the death of Joseph, or a period of 2369 years. (See article CHRONOLOGY.)

* Edinburgh Encyclopædia, article THEOLOGY.

Exodus, the title of the second book of Moses, signifies in Greek *The going out*, and was applied from the account which it gives of the Israelites going out of Egypt. In it are related the cruel Egyptian slavery under which the Jews groaned; their delivery by flight and a passage through the Red Sea; the history of the establishment of their very peculiar law, and many remarkable transactions; concluding with the building of the Tabernacle, or place appropriated to the service of the Divinity. This book comprises the history of 145 years, from the death of Joseph till the building of the Tabernacle. The Hebrews call it *Veelle Shemoth*, that is, in English, *These are the names*, which are the words with which it begins.

The third book of Moses is called *Leviticus*, because it contains the laws which God commanded should be observed by those of the tribe of *Levi* who ministered at the altar. It treats at large of all the functions of the Levites; of the ceremonial of religion; of the different sorts of sacrifices; of the distinction of clean and unclean beasts; of the different festivals; and of the year of jubilee, or continued holiday. It likewise presents us with an account of what happened to the Jews during the space of one month and a half; that is, from the time the Tabernacle was erected, which was the first day of the first month of the second year after the Israelites came out of Egypt, till the second month of the same year, when God commanded the people to be numbered. The Hebrews call this book *Vayicre*, that is, *And he called*, these being the first words; they call it also the *Law of the Priests*.

In the fourth book, which we call *Numbers*, Moses numbers the Israelites, and that, too, in the beginning of the book, which shows whence it had its name. The Hebrews call it *Vayedaber*, that is, *And he spake*. This book contains the history of all that passed from the second month of the second year after the Israelites came out of Egypt, till the beginning of the eleventh month of the fortieth year; that is, it contains the history of thirty-nine years, or thereabouts. In it we have also the history of the prophet Balaam, whom the King of the Midianites brought to curse the people of God, and who, on the contrary, heaped blessings upon the Israelites, and foretold the coming of the Messiah. It particularly mentions, also, the two-and-forty encampments of the Israelites in the wilderness.

The fifth book is called *Deuteronomy*, a Greek term, which signifies *The second law*, or rather, *The repetition of the law*, because it does not contain a law different from that which was given on Mount Sinai; but it repeats the same law, for the sake of the children of those who had received it there, and were since dead in the wilderness. The Hebrews call it *Elle-haddebarim*, that is, *These are the words*. Deuteronomy begins with a short account of what had passed in the wilderness, and then Moses repeats what he had before commanded, in *Exodus*, *Leviticus*, and *Numbers*, and admonishes the people to be faithful in keeping the commandments of God. After this, he relates what had happened from the beginning of the eleventh month to the seventh day of the twelfth month of the same year, which was the fortieth after their leaving Egypt. The discourse which is at the beginning of this book was made to the people by Moses on the first day of the eleventh month. According to Josephus, he died on the first day of the twelfth; and the Israelites, as the Scripture says, mourned for him in the plains of Moab thirty days, and, consequently, during the whole of the twelfth month.

The Jews call the *Pentateuch* the *Law*, without doubt, because the law of God, which Moses received on Mount Sinai, is the principal part of it; and it is as little to be doubted whether that great man was the writer of the *Pentateuch*. This is expressly declared both in *Exodus* and *Deuteronomy*. But as an account of the death of Moses is given in the last eight verses of this book, it is therefore thought that these verses were added either by Joshua or Ezra. The opinion of Josephus concerning them is very singular; he assumes that Moses, finding his death approaching, and being

willing to prevent an error into which the veneration the people had for him might cause the Jews to fall, wrote this account himself; without which the Jews would probably have supposed that God *had taken him away*, like Enoch.

After the death of Moses, Joshua, by the order of the Divine Being, took upon himself the conducting of the Hebrew people, and succeeded Moses, to whom he had been a faithful servant, and by whom he had been instructed in what he ought to do. It is uncertain whether the book which contains the history of this successor of Moses be called *Joshua*, from the subject of it, or from his having been the writer of it. But it is certain that it contains an account of what passed from the death of Moses to that of Joshua. Nevertheless, there are several things in it which did not come to pass till after the death of this great man, and which, consequently, could not have been written by him. The common opinion as to the length of time it contains is, that Joshua discharged his office only for seventeen years, and that, therefore, this book contains no more than the history of that number of years.

After the death of Joshua, the Israelites were governed by magistrates, who ruled under the general designation of *Judges*; and the book which contains the history of these rulers is called the *Book of Judges*. This history begins with the death of Joshua, and reaches to that of Samson. We here see the people of God often enslaved in punishment of their crimes, and often wonderfully delivered from slavery. Towards the end of it, we have some instances of this people's inclination to idolatry, and of the corruption of their manners, even before they had been brought into slavery. Such are the histories of Micah, and of the Benjaminites who abused the Levite's wife. This book contains the history of about three hundred years.

During the time of the government of Judges, there was a great famine in the land of Israel, which forced Elimelech, a native of Bethlehem, to retire into the land of Moab, with his wife Naomi and two children. Elimelech died there, as also his two sons, who had married two Moabitish women, one of whom was named Ruth. Naomi, after the death of her husband and her children, returned to Bethlehem, accompanied by Ruth, her daughter-in-law, who was there married to Boaz, Elimelech's near relation, and the heir to his estate. The book which contains this history is called the *Book of Ruth*. The beginning of it shows that it happened in the time of the Judges, but under which of them is not certainly known: some place it in the time of Shamgar, or of Deborah. As to the writer of this book, some think that the books of Judges and Ruth were both written by Samuel; others attribute them to Hezekiah, and others to Ezra. The Jews place the book of Ruth among the five books which they usually read on all the festivals in the year. These five books are, the Song of Songs, Ruth, the Lamentations of Jeremiah, Ecclesiastes, and the book of Esther. In the Hebrew bibles they are printed or written apart by themselves, and are bound up together.

The four books following Ruth are called by the Greeks, and also in some Latin bibles, the *History of the Reigns*. Others call them all the *Books of Kings*, because they give an account of the establishment of the monarchy, and of the succession of the kings, who reigned over the whole kingdom at first, and over the kingdoms of Judah and Israel after its division. At the beginning of these books is the history of the prophet Samuel, which gives light to that of the kings. The Jews call the first two of these books the *Books of Samuel*, perhaps because they contain the history of the two kings who were both anointed by Samuel, and because what is said of Saul in the *first*, and of David in the *second*, proves the truth of Samuel's prophecies. They give the name of the *Books of Kings* only to the other two, which in the Latin and French bibles are called the *third* and *fourth Books of Kings*.

The *first Book of Kings*, or the *first of Samuel*, contains the history of the high-priest Eli, of Samuel, and

of Saul; and extends over a period of nearly eighty years.

The *second* contains the reign of David, which is the history of about forty years. It is commonly believed that Samuel, Nathan, and Gad, were the writers of these two books; and indeed they are called, in the end of the first book of *Chronicles*, *David's historians*.

The *third*, or, according to the Hebrews, the *first Book of Kings*, begins with a relation of the manner in which Solomon came to the throne, and contains the whole of his reign. After that, an account follows of the division of the kingdom, and the history of four kings of Judah and eight kings of Israel. All these reigns, including that of Solomon, which occupies the first forty years, comprise the space of 126 years.

The *fourth* of these books contains the history of sixteen kings of Judah and twelve kings of Israel; and embraces a period of three hundred years. It likewise gives an account of the prophets who lived during this time. It is quite uncertain who were the writers of the two last-mentioned books. They are by some attributed to Jeremiah or Ezra, but no very convincing proofs have been adduced in support of this opinion. It is evident, indeed, that these books form a varied collection of several particular histories.

The name of *Paralipomena*, which, in Greek, signifies the *history of things omitted*, is given to the two books which follow those of the *Kings*. These form, in fact, a supplement, containing what had been omitted in the *Pentateuch*, and the books of *Joshua*, *Judges*, and *Kings*, or rather they contain a fuller description of some things which had been therein only briefly related. Some give them the name of *Chronicles*, because they are very exact in mentioning the time when every transaction happened. We divide them into two books, as do also the Jews, who call them *Dibere Hayamim*, that is, an *Historical Journal*, the matters of which they treat having been taken from the Journals of the Kings. In the original language, however, the word *days* often signifies the *year*, and in this sense we may understand the term to signify properly *Annals*. The generally received opinion is, that Ezra was the compiler of these. In the *first* book, he begins with a succinct historical abridgment, from the creation of Adam to the return of the Jews from their captivity; and then he resumes the history of David, and carries it on to the consecration of Solomon, that is, down to the year before Christ 1015. The history contained in the *second* book reaches down to the year before Christ 536, when, upon the expiration of the seventy years of the captivity, Cyrus gave the Jews leave to return to their own country.

Ezra wrote the history of the return of the Jews from the captivity of Babylon into Judea. It is the history of about eighty-two years, from the year of the world 3468, when Cyrus became master of the eastern empire, by the death of his father Cambyzes in Persia, and his father-in-law Cyaxeres in Media, to the year 3550, which was the twentieth year of the reign of Artaxerxes, surnamed Longimanus. This book bears the name of Ezra, who was the writer of it.

The next book is a continuation of that of Ezra, and, therefore, it is by some called the *Second Book of Ezra*. It was Nehemiah, however, whose name it also bears, who wrote it, as is said, by the advice of Ezra. It contains the account of the re-establishment of Jerusalem, and of the Temple, and the worship of God. It is believed by some writers to be the history of about thirty-one years; but its chronology is exceedingly uncertain.

After this general history of the Jews, follow two histories of particular persons, namely, *Esther* and *Job*. The first contains the account of a miraculous deliverance of the Jews, which was accomplished by means of the heroine named Esther. The history of Job is not only a narration of his actions, but contains also the entire discourses which this pious man had with his wife and his friends, and is, indeed, one of the most eloquent and poetic books in the Holy Scriptures. It is uncertain who was the author,

Next to the *historical* books of Scripture, follow those of a moral nature. The first of these is the book of *Psalms*, which are likewise in some measure historical; for they recite the miracles which God had wrought, and contain, as it were, an abridgement of all that had been done for the Israelites, and that had happened to them. The Hebrews call them the *Book of Praises*, by which they mean, *of the praises of God*. The word *psalm* is Greek, and properly signifies the sound of a stringed instrument of music. The Hebrews sung the psalms with different instruments. We make but one book of them all, but the Hebrews divide them into five parts, which all end with the words *Amen, Amen*. Though the Psalms bear the name of David, yet they were not all composed by him: some of them are more ancient, and others are of a later date than his time; some of them being ascribed to Moses, Samuel, and Ezra. Speaking of the dedication of the second temple, Prideaux says, "In this dedication, the 146th, the 147th, and the 148th Psalms, seem to have been sung; for, in the Septuagint versions, they are styled the *Psalms of Haggai and Zechariah*, as if they had been composed by them for this occasion; and this, no doubt, was from some ancient tradition; but in the original Hebrew, these psalms have no such title prefixed to them, neither have they any other to contradict it." It is not probable, however, that all those whose names they bear were the true authors of them: it is more likely that these are only the names of those to whom they were first given to sing.

After the Psalms are the *Proverbs*, which are a collection of moral sentences, of which Solomon was the writer. This name is given them by the Greeks, but the Hebrews call them *Miste*, that is, *Parables*, or *Comparisons*; and the word may also signify *Sentences*, or *Maxims*. It is a collection of divine precepts, proper for every age and every condition of life.

The book which follows is also a *moral* one, and was likewise composed by Solomon. The Greeks call it *Ecclesiastes*, which answers to the name of *Koheleth*, which it bears in the Hebrew. Both these words signify, in our language, *a preacher*, or *one who speaks in an assembly*. In this book is given an admirable picture of the vanity of worldly expectations.

Among the *moral* books is also reckoned the *Song of Songs*; that is to say, according to the Hebrew manner of speaking, *a most excellent song*. It is an inspired production of Solomon, in the allegorical form of an *epithalamium*, or nuptial song significant of the marriage and fellowship between Christ and his people: "Its majestic style, its power on men's consciences to promote holiness and purity, the harmony of its language with that of Christ's parables, and of the book of Revelation; the sincerity of the bride in acknowledging her faults; and, in fine, its general reception by the Jewish and Christian church, sufficiently prove its authenticity."—Brown.

In regard to the Prophets, it may be observed, that all the Old Testament is considered to be in substance one continued prophecy of the coming of a Messiah; so that all the books of which it consists are understood to be in some sense *prophetical*. But this name is more especially given to those books which were written by persons who had a clearer knowledge of futurity, who forewarned both kings and people of what would happen to them, and who, at the same time, pointed out what the Messiah was to accomplish, whom they who are acknowledged to have been prophets had always in view; and this is what ought most especially to be taken notice of in their writings.

The Prophecies bear the names of those to whom they belong. Some learned men are of opinion that the Prophets made abridgements of the discourses which they had written, and fixed them up at the gates of the Temple, that all the people might read them; and that after this the ministers of the Temple might take them away, and place them among the archives, which is the reason why we have not the Prophecies in the order in which they were written. But the interpreters of Scrip-

ture have long since laboured to restore that order, according to the course of their history.

The works of the Prophets are divided into two parts, the first of which contains the *Greater*, and the second, the *Lesser Prophets*. This distinction, of course, does not apply at all to the persons of the prophets, but only to the bulk of their works. The *Greater Prophets* are Isaiah, Ezekiel, Daniel, and Jeremiah. The *Lamentations* of Jeremiah make a separate book by themselves, containing that prophet's descriptions of the destruction of the city of Jerusalem and of the captivity of the people. The *Lesser Prophets* are Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi. They were formerly contained in one single volume, which the Hebrews call *Thearaser*, which means *Twelve*, or *the Book of the Twelve*.

The dates of many of the prophecies are uncertain, but the earliest of them was in the days of Uzziah, King of Judah, and Jeroboam the Second, his contemporary, King of Israel, about two hundred years before the captivity, and not long after Joash had slain Zechariah, the son of Jehoiada, in the court of the temple. Hosea was the first of the writing prophets, and Joel, Amos, and Obadiah, published their prophecies about the same time.

Isaiah began his remarkable prophecies a short time afterwards, but his book is placed first, because it is the largest of them all, and is more explicit respecting the advent of Christ than any of the others. The language of this eminent writer is exceedingly sublime and affecting; so much so, that it has never been equalled by any profane poet either in ancient or modern times. It is impossible to read some of the chapters without being struck by the force of the prophetic allusions to the character and sufferings of the Messiah; and, in consequence of these prevailing characteristics, the author is ordinarily styled the *Evangelical Prophet*, and by some of the ancients, a *Fifth Evangelist*. The Jews say that the spirit of prophecy continued forty years during the second Temple; and Malachi they call the Seal of Prophecy, because in him the succession or series of prophets broke off, and came to a period. The book of Malachi, therefore, appropriately closes the sacred record of the Old Testament.

By referring to our historical sketch of the Jewish people,* it will be observed that the glory of Israel vanished at the period of the conquest and captivity of the nation, about six hundred years before Christ. As a consequence, though not an immediate one, the inspired writings of the Old Testament were concluded soon after this event, or probably four hundred years before the coming of the Messiah. Thus, a period of from four to five centuries elapsed from the time when Malachi concluded his prophetic enunciations, till that in which the Evangelists penned the books descriptive of Christ's life and ministrations.

NEW TESTAMENT.

The second and lesser division of the Bible, as has been said, relates entirely to the Christian religion, or the fulfilment of that which was predicted and prefigured in the more ancient department of the work. This division of the Sacred Scriptures is generally styled the *New Testament*, or that which has been a later revelation and bequest; that portion of it which relates to the history of the life of Christ is called the *Gospel*, and by some the *Evangel*, both these words having the same meaning, and implying *good news*, or *glad tidings*, from the circumstance that the narratives contain an account of things which are to benefit mankind.

The New Testament, like the Old, is a compilation of books written by different inspired individuals, and all put together in a manner so as to exhibit a regular account of the birth, actions, and death of Christ—the doctrines he promulgated—and the prophecies regarding the future state of the church which he founded.

* No. 6. in the present series.

The historical books are the four *Gospels* and the *Acts of the Apostles*, all these being of the character of narratives of events; the doctrinal are the Epistles of Paul, and some others; the prophetic book is the last, and is called the *Revelations* or *Apocalypse of St John*, having been written by that apostle while he was in the island of Patmos.

The four Evangelists, or writers, are Matthew, Mark, Luke, and John; these having, as is generally believed, been companions of Christ during his ministrations, and therefore personally acquainted with his life and character. Each of the four books is principally a repetition of the history of Christ, yet they all possess a difference of style, and each mentions some circumstances omitted by the others, so that the whole is essential in making up a complete life of the Messiah. These distinctions in the tone of the narratives, and other peculiarities, are always considered as strong circumstantial evidence in proof of their authenticity, and of there having been no collusion on the part of the writers. But, indeed, the events they record are detailed in so exceedingly simple and unaffected a manner, that it is impossible to suppose that they were written with a view to impose on the credulity of mankind. The veracity and actual belief of the Evangelists themselves are placed beyond a doubt.

The first book is written by Matthew, who was by birth a Jew, and exercised the profession of a publican—that is, a collector of the public tax or assessment imposed upon the Jewish people by their conquerors, the Romans. Matthew, who was also called by the name of Levi, was one of the twelve apostles of Christ, and he is said to have written his narrative from thirty to forty years after the departure of his Master from the earth. Many of the ancients say that he wrote it in the Hebrew or Syriac language; but it is more probable that there were two originals—one in Hebrew, and the other in Greek, the former written A.D. 37 or 38, and the latter A.D. 61; and that these were respectively designed for the Hebrew and Gentile nations.

With regard to Mark, the writer of the second Gospel, it may be observed, that although Mark or Marcus was a common Roman name, there is reason to believe that this Evangelist was a Jew, who had changed his original appellation on being converted to the faith of Christ. Jerome says, that, after the writing of this Gospel, he went into Egypt, and was the first that preached the Gospel at Alexandria, where he founded a church, to which he offered an example of holy living.

The Gospel of St Mark is much shorter than that of Matthew, not giving so full an account of Christ's sermons as that did, but insisting chiefly on his miracles; and in regard to these also, it is very much a repetition of what we have in Matthew, many remarkable circumstances being added to the incidents there related, but not many new matters. There is a tradition that it was first written in Latin, because it was written at Rome; but this is generally thought to be without foundation, and that it was written in Greek, as was St Paul's Epistle to the Romans, the Greek being the more universal language. The Gospel of Mark was written at a somewhat later period than that of Matthew.

Luke, the name of the third Evangelist, is considered by some to be a contraction of *Lucilius*; and he is said by St Jerome to have been born at Antioch. Some think that he was the only one of all the penmen of the Scriptures that was not of the Israelites; that he was a Jewish proselyte, and was converted to Christianity by the ministry of St Paul at Antioch; and that, after the coming of Paul into Macedonia, Luke was his constant companion. He had employed himself in the study and practice of physic; and hence Paul calls him *Luke the beloved Physician*. It is deemed probable that Luke wrote both his gospel and his narrative of the *Acts of the Apostles* at Rome, when he was there a prisoner with Paul, *preaching in his own hired house*—circumstances alluded to at the conclusion of the latter work. If this be the case, Luke's Gospel may be dated about thirty years after Christ's departure, or A.D. 63. Jerome

says that St Luke died when he was eighty-four years of age, and that he was never married. Dr Cave observes, that "his way and manner of writing are accurate and exact, his style polite and elegant, sublime and lofty, yet perspicuous; and that he expresses himself in a vein of purer Greek than is to be found in the other writers of this holy history." Thus he relates several things more copiously than the other Evangelists, and thus he especially treats of those things which relate to the priestly office of Christ.

The fourth Evangelist, John, was one of the sons of Zebedee, a fisherman of Galilee, the brother of James, one of the Twelve Apostles, and distinguished by the honourable appellation of *that disciple whom Jesus loved*. The ancients tell us that John lived longest of all the Apostles, and was the only one of them that died a natural death, all the rest suffering martyrdom. It is now established that he wrote his Gospel about the year 97 or 98, when he was of an extremely old age.

After the Gospel, or History of Jesus Christ, follows the history of what passed after his ascension and was transacted by the Apostles. The book, therefore, which contains this history, is called the *Acts of the Apostles*. It is a history of the rising church for about the space of thirty years. It was written, as has been already observed, by St Luke the Evangelist, when he was with St Paul at Rome, during his imprisonment there. In the end of the book he mentions particularly his being with Paul in his dangerous voyage to Rome, when he was carried thither a prisoner; and it is evident that he was with him when, from his prison there, Paul wrote his epistles to the Colossians and Philemon, for in both of these he is named by him.

Next to this come the *Epistles of St Paul*, which are fourteen in number; one to the Romans; two to the Corinthians; one to the Galatians; one to the Ephesians; one to the Philippians; one to the Colossians; two to the Thessalonians; two to Timothy; one to Titus; one to Philemon; and one to the Hebrews. They contain that part of ecclesiastical history which immediately follows after what is related in the Acts. The principal matter contained in them is the establishment or confirmation of the doctrine which Jesus Christ taught his disciples. According as the difficulties which raised disputes among the Christians, or the heresies which sprang up in the church from the first age of it, required, St Paul in these epistles clears up and proves all matters of faith, and gives excellent rules for morality. His epistles may be considered as a commentary on, or an interpretation of, the four books of the Gospel.

The Epistle to the *Romans* is placed first, not because of the priority of its date, but on account of its superlative excellence, it being one of the longest and fullest of all, and, perhaps, also, on account of the dignity of the place to which it is addressed. It is gathered from some passages in the epistle, that it was written in the year of Christ 56, from Corinth, while Paul made a short stay there in his way to Troas. He was then going up to Jerusalem, with the money that was given to the poor saints there; which is spoken of in the fifteenth chapter of the epistle.

The two Epistles to the *Corinthians* were written about a year after that to the Romans, viz. A.D. 57; that to the *Galatians*, A.D. 56; to the *Ephesians*, A.D. 61; to the *Philippians*, A.D. 62; to the *Colossians*, A.D. 62; two to the *Thessalonians*, A.D. 51 and 52; the first to *Timothy*, A.D. 64; the second to *Timothy*, A.D. 66; to *Titus*, A.D. 65; to *Philemon*, A.D. 62; and that to the *Hebrews*, A.D. 62. From which chronology it appears, that the Epistles of St Paul are placed in the New Testament rather according to the dignity of the cities to which they were sent, than according to the order of time in which they were written; for the Epistles to the Thessalonians were those he wrote first, though that to the Romans is placed before them. Interpreters are agreed that the last epistle which he wrote was the second to Timothy.

St Paul wrote to the churches of some particular places, or to some particular persons; but the other

epistles which follow his are called *catholic* (that is, universal), because, with the exception of the second and third of St John, they were not addressed to any particular church or individual, as his were, but to the whole church in general. These are—one of St James; two of St Peter; three of St John; and one of St Jude.

The date of most of these epistles is extremely uncertain, but the most generally received chronology of them is as follows:—That of St James, A.D. 61; of St Peter, A.D. 66 and 67; of St John, A.D. 80 and 90; of St Jude, A.D. 66.

It has sometimes occurred to the minds of well-disposed persons, that it would have been better for Christianity had there never been any other record of its origin and doctrines than the writings of Matthew, Mark, Luke, and John. But, however plain and satisfactory the histories of these Evangelists may be, and however little they admit of controversy, it may, on the other hand, be observed, that the strong arguments and illustrations brought forward in the Epistles by Paul and others, were necessary, in order to combat the sophistry of the Greeks and the self-sufficient philosophies of other nations. Paul, the chief of the epistle writers, who became a Christian by conversion, after Christ had departed from the earth, is the great champion of the faith, and exposes, in strong and perspicuous language, the hidden depravities of the human heart; so that, where the affecting discourses and sufferings of the Messiah fail to convert and to convince, the reasoning of this great writer is calculated to silence and subdue those who stubbornly resist the benignant influence of the Christian faith.

Such, then, were the various books written to convey to posterity a faithful account of Christ's life and mission, and consequently of the religion which it was his purpose to institute. It will have been observed, that the whole were inscribed within the first century, and gradually accumulated in the hands of the primitive church, as an imperishable basis on which the faith of Christians should be founded.

AUTHENTICITY OF THE SCRIPTURES.—APOCRYPHA.

With respect to the authenticity of both the Old and New Testament books, as generally received, we of course look to the estimation in which they were respectively held by those with whom they had been deposited, and who unquestionably possessed the best evidences of their credibility. The Jews, as is well known, were most scrupulous in preserving entire the works of their inspired writers, and of preventing the intrusion of literal errors into the copies which were from time to time transcribed. Of the fidelity of the original text, there cannot, we think, be any reasonable doubt; and although there are what are called various readings, these are of an exceedingly unimportant character. Referring to this subject, it is said by the learned Dr Adam Clarke, "that all the omissions of the ancient manuscripts, put together, would not countenance the omission of any essential doctrine of the gospel, relative to faith or morals; and all the additions countenanced by the whole mass of manuscripts already collated, do not introduce a single point essential either to faith or morals, beyond what may be found in the Complutensian or Elzevir editions." Among other means adopted by the Jews to preserve the integrity of the Scriptures, was that of noting and recording the exact number of words, verses, points, and accents, in each book. The duty of doing so was the province of the Jewish doctors or learned men, called Masorites. By these acute grammarians, all the verses of each book and of each section were numbered, and the amount placed at the end of each in numerical letters, or in some symbolical word formed out of them; the middle verse of each book was also marked, and even the very letters were numbered; and all this was done to preserve the text from any alteration, by either fraud or negligence. For instance, Bereshith, or Genesis, is marked as containing 1534 verses, and the middle one

is at—"And by thy sword thou shalt live" (xxvii. 40). The lines are 4395; its columns are 43, and its chapters 50. The number of its words is 27,713, and its letters are 78,100. The Masoritic notes, or Masorah, as the work is called, contain also observations on the words and letters of the verses; for instance, how many verses end with the letter *samech*; how many there are in which the same word is repeated twice or thrice; and other remarks of a similar nature.

It seems now generally agreed upon that the Masorites of Tiberias, during the fourth century of the Christian era, were the inventors of the system of the *vowel-points* and *accents* in the Hebrew Bible; and although they multiplied them very unnecessarily, it must be allowed that they were an improvement of considerable importance. From the *points* we learn how the text was read in their time, as we know they were guided in affixing them by the mode of reading which then prevailed, and which they supposed to have been traditionally conveyed down from the sacred writers.

The respect which the Jews have uniformly paid to the sacred books, has been almost allied to superstition. They are directed to be written upon parchment, made from the skin of a clean animal, and to be tied together with strings of similar substance, or sewn with goats' hair which has been spun and prepared by a Jewess. It must be likewise a Jew that writes the Law, and they are extremely diligent and exact in it, because the least fault profanes the book. Every skin of parchment is to contain a certain number of columns, which are to be of a precise length and breadth, and to contain a certain number of words. They are to be written with the purest ink, and no word is to be written from memory; it must be first orally pronounced by the copyist. The name of God is directed to be written with the utmost attention and devotion, and the transcriber is to wash his pen before he inscribes it on the parchment. If there should chance to be a word with either a deficient or a redundant letter, or should any of the prosaic part of the Old Testament be written as verse, or *vice versa*, the manuscript is vitiated. No Hebrew manuscript with any illumination is, on any account, admitted into a synagogue, although private individuals are permitted to have them ornamented for their own use; but in the illustrations, the resemblance of any animal denounced by the Jews as unclean cannot be admitted. Among the modern Jews, the Book of Esther, in particular, is frequently decorated with rude figures of various kinds; but with respect to this book, it must be observed, that, owing to its wanting the sacred name of God, it is not held in such repute for holiness as the other books are. The manuscripts for private use may be either upon parchment, vellum, or paper, and of various sizes. "There is," says Prideaux, "in the church of St Dominic, in Bononia, a copy of the Hebrew Scriptures, kept with a great deal of care, which they pretend to be the original copy, written by Ezra himself; and, therefore, it is there valued at so high a rate, that great sums of money have been borrowed by the Bononians upon the pawn of it, and again repaid for its redemption. It is written in a very fair character, upon a sort of leather, and made up in a roll, according to the ancient manner; but its having the vowel-points annexed, and the writing being fresh and fair, without any decay, both these particulars prove the novelty of that copy."

To open and shut up the roll or book of the Law, to hold it, and to raise and show it to the people, are three offices, which are sold, and bring in a great deal of money. The skins on which the Law is written are fastened to two rollers, whose ends jut out at the sides beyond the skins, and are usually adorned with silver; and it is by them that they hold the book when they lift it up, and exhibit it to the congregation; because they are forbidden to touch the book itself with their hands. All who are in the synagogue kiss it, and they who are not near enough to reach it with their mouths, touch the silken cover of it, and then kiss their hands,

and put the two fingers with which they touched it upon their eyes, which they think preserves the sight. They keep it in a cupboard, which supplies the place of the ark of the covenant, and they therefore call this cupboard *Aron*, which is the Hebrew name for the *Ark*; and this is always placed in the east end of the synagogue. He who presides chooses any one whom he pleases to read and explain the Scripture, which was a mark of distinction, as we see in the thirteenth chapter of the *Acts*, where we find the rulers of the synagogue desiring the Apostles, when they were in the synagogues, to make a discourse to the people. Ordinarily speaking, a priest began, a Levite read on, and at last one of the people, whom the president chose, concluded. He who reads stands upright, and is not suffered so much as to lean against a wall. Before he begins, he says with a loud voice, *Bless ye God*, and the congregation answers, *Blessed be thou, O my God; blessed be thou for ever*; and when the lesson is ended, the book is rolled up, and wrapped in a piece of silk.

Certain books, collectively termed the *Apocrypha*, are sometimes included in the Bible, and of these it is necessary to give a brief account. The term *Apocrypha* is Greek, signifying *hidden* or *concealed*, and is applied to those books whose origin is unknown, or the authenticity of which is either doubtful or absolutely denied. Some writers divide the sacred books into three classes—the canonical, the ecclesiastical, and the apocryphal. In the first they place those whose authority has never been questioned in the catholic or universal church; in the second, those which were not received at first, but which were nevertheless read in the public assemblies, as books that were useful, though they never placed them upon the same footing of authority as the former; and in the third, they placed the books which were of no authority, which could not be made to appear in public, but were kept *hidden*, and were therefore called *apocryphal*, that is, *concealed*, or such as could not be used in public. "Let us lay aside those books which have been called *apocryphal*," says St Augustine, "because their authors were not known to our fathers, who have, by a constant and certain succession, transmitted down to us the authority and truth of the Holy Scriptures. Though some things in these apocryphal books are true, yet as there are in them multitudes of others which are false, they are of no authority."

The *Apocrypha* consists of fourteen books, namely, *First and Second Esdras*, *Tobit*, *Judith*, the rest of the chapters of the book of *Esther*, the *Wisdom of Solomon*, *Ecclesiasticus*, *Baruch*, the *Song of the Three Holy Children*, the *History of Susanna*, the *Story of Bel and the Dragon*, the *Prayer of Manasses*, and the *First and Second Book of the Maccabees*. Biblical historians assert that these books were of a later composition than the other parts of Scripture, never existed in the proper Hebrew tongue, and were at no time received by the Jews as the writings of inspired men. It is the general belief of such Scripture critics as have made this subject their study, that the whole or greater part of the *Apocrypha*, was written between the time of the Babylonish captivity and the appearing of Christ, and by persons who had mixed with the Greeks and other foreign nations. The apocryphal books, it is observed, are never quoted in the New Testament, or by the Jewish writers Philo and Josephus; and by the early councils of the Church they were formally excluded from the canon. On these points, however, as is well known, there exists a great difference of opinion—the Roman Catholic Church viewing the apocryphal books as canonical, and the Protestants entirely setting them aside, or using them only as works of ordinary edification, or for the light which they throw on the phraseology of Scripture and the history and manners of the East. With respect to the meaning and application of the term *canonical*, we have appended a note beneath.*

While attempts have been made to intrude uncanonical books into the authentic body of ancient Scripture, the New Testament has been exposed to similar vitiation. In the third and fourth centuries, there were gospels forged by divers sects, and published, one under the name of St Peter, another of St Thomas, another of St Philip, &c. But they were never owned by the church, nor was any credit given to them, as the learned Dr Whitby shows. And he gives this good reason why we should adhere to records written at or near the time of Christ—"Because," says he, "whatever the pretences of tradition may be, it is not sufficient to preserve things with any certainty, as appears by experience. For whereas Christ said and did many memorable things, which *were not written*, tradition has not preserved any one of them to us, but all is lost except what was written; and that, therefore, is what we must abide by."

What has been said of the integrity of the text of the Old Testament, may be applied also to the New, in as far as it may be charged with corruptions in consequence of the negligence of transcribers. Though it must be admitted that the New Testament text, by being more frequently transcribed than the Old, became liable to a greater proportion of various readings, originating from the mistakes of the transcribers, yet this very circumstance was likewise a sure protection; thence canon is used to denote the rule or standard of primitive Christianity. The same term is employed to designate the collection of books containing this rule, that is, the canonical books of the Holy Scriptures which the Church acknowledges. The canon of the books of the Old Testament, as drawn up by the Jews in the fourth century before Christ, receives in this form equal respect among all Christians, because Christ and his apostles have expressly appealed to them, and pronounced them writings inspired by God. The apocryphal books of the Old Testament, whose canonical character the Jews did not acknowledge, the Eastern [or Greek] Church has never received; but the Western [or Roman] Church declared them canonical, in the African council, about the end of the fourth century." What follows is said to be the explanation of a Catholic. "The Holy Scriptures are esteemed sacred by the Catholics, because the Church has transmitted them from age to age as sacred, and illustrative of revelation, as far as any writings can be. The Church has only declared what writings have been handed down as of divine origin. The catalogue of these Holy Scriptures is the canon; the writings themselves are called canonical books. In this sense, the Protestant Church has no canon; it rejects the authority of all traditions of the Church. Hence, in order to be consistent, it must leave every Protestant, on free investigation, to decide what books he will regard as canonical. But the Bible, the pillar of the Protestant faith, is made up of separate canonical books; and by pursuing such a course, the basis of the Protestant faith might be undermined. It has been agreed, therefore, however inconsistently, to adopt the New Testament canon of the Catholic Church. But, in fixing the canon of the Old Testament, the decisions of the Catholic Church have been rejected; and, contrary to the African councils and the usage of the Romish Church, established by the Council of Trent, part of *Esther*, also *Baruch*, *Tobit*, *Judith*, *Wisdom*, *Ecclesiasticus*, or *Jesus the Son of Sirach*, the *Two Books of Maccabees*, the *Song of the Three Youths in the Fiery Furnace*, described in *Daniel*, together with the last two chapters of this prophet, are thrown out as uncanonical or apocryphal. It is worthy of mention, that a controversy on this subject broke off the negotiations for a union of the Catholic and Protestant Churches, which commenced in the beginning of the eighteenth century between Leibnitz, Molanus, and Bossuet." The above explanation is scarcely correct, as respects the Protestant idea of the canon of Scripture. The church of England, for example, does not implicitly adopt the Roman Catholic canon: it founds its rule of faith on that which is believed to have been the canon in the earliest centuries of Christianity. "The Church of England, in determining the sense of the Bible, listens with respect to the voice of the most ancient fathers and doctors; and not only with respect, but even with submission, where that voice is all but unanimous."—*Life of Jewel*. "The Council of Trent confirmed the decision of some previous councils, by which the books of the *Apocrypha* were declared to belong to the canon of the Old Testament; contrary to that of the council of Laodicea, A. D. 364, which, by an express canon, sanctioned the catalogue of the sacred books as received by Protestants."—*Josiah Conder's View of all Religions*.

* The meaning of this term will be gathered from the following explanations in the *Encyclopædia Americana* (Conversations Lexicon):—"The term *canon* (Greek) signifies a measure, rule,

tion against wilful perversion or corruption; for, in proportion as copies were multiplied, the difficulty of effecting a general corruption was increased. No such system as that of the Masorites was ever adopted to preserve the purity of the New Testament text; but we have it in our power to use various means for ascertaining what is the true reading of the text, without having recourse to such a plan as that of the Masorah; and Concordances, which are now brought to an uncommon degree of perfection, are of great use in preserving it from corruption. It need only be added, that we have the consent of the church, in all ages and countries, to prove the fidelity of the New Testament Scriptures, and any variety occurring in the readings in modern times can arise only from heedlessness, or motives of an improper kind.

With respect to the credibility, on general grounds, of the New Testament writers, and that the books are of that antiquity usually assigned to them, there cannot be any reasonable doubt; in other words, the writers wrote the books in perfect good faith, believing that what they penned was true, and the very books are those now before us in the New Testament. On these points, an able divine remarks:—"It must be esteemed a strong circumstance in favour of the antiquity of the New Testament, that on a subject in which the chances of detection are so numerous, and where we can scarcely advance a single step in the narrative without the possibility of betraying our time by some mistaken allusion, it stands distinguished from every later composition, in being able to bear the most minute and intimate comparison with the contemporary historians of that period. The argument derives great additional strength from viewing the New Testament, not as one single performance, but as a collection of several performances. It is the work of no less than eight different authors, who wrote without any appearance of concert, who published in different parts of the world, and whose writings possess every evidence, both internal and external, of being independent productions. Had only one author exhibited the same minute accuracy of allusion, it would have been esteemed a very strong evidence of his antiquity. But when we see so many authors, exhibiting such a well-sustained and almost unexpected accuracy through the whole of their varied and distinct narratives, it seems difficult to avoid the conclusion, that they were either the eye-witnesses of their own history, or lived about the period of its accomplishment."*

A minor point in the history of the Bible now requires to be noticed. In the earliest times the writings of the Old Testament were divided into books and short paragraphs equivalent to verses; but the division into chapters and verses in which they now appear was of a much later date. The separation of both the Old and New Testament books into chapters and verses, is by some writers ascribed to Arlott, a Tuscan monk, or rather to Hugh Cardinalis in the thirteenth century; while others allege that, from the comments of Theophylact on the Gospel, this must have been effected two centuries earlier. The question is not very important, and it is sufficient for the purposes of general knowledge to be informed, that the division of the Scriptures into chapters and verses was the work of a Roman Catholic divine some time between the eleventh and thirteenth centuries.

MODERN HISTORY OF THE BIBLE.

It will have been gathered from the preceding details, that the books of the Old Testament were originally written in the Hebrew language, that being the tongue spoken by the ancient Jewish people; and that the books were inscribed on rolls or sheets of carefully prepared parchment, and deposited only in the Temple, or preserved in the hands of the highest officers of religion. In this condition, and either in the Hebrew or Chaldaic tongue, they existed till translated into the language of the Greeks, under the name of the Septua-

gint. With respect to the exact period at which this translation was effected, history presents no uniform account. The translation is ordinarily assigned to seventy Jewish elders or interpreters—and hence the term *Septuagint*, which signifies seventy—who were employed by the Egyptian ruler, Ptolemy Philadelphus, to furnish a copy of the Scriptures in Greek, a language with which he and his people were acquainted. Whether the narration of this circumstance, which is said to have occurred 277 years before the Christian era, be conformable with credible history, it is at least certain that the translation called the Septuagint was effected by Jews skilled in the Greek tongue, at about the time specified, and it was afterwards held in high esteem by the Sanhedrim at Jerusalem. It may further be explained, that it was this Greek version of the Scriptures which was always quoted by our Saviour and his apostles, whenever they made an appeal to the sacred writings. With the earliest organisation of the Christian church may be said to have commenced a new era in the history of the Bible. The Old Testament books, whether in the form of Hebrew, Chaldaic, or Greek versions, were still cherished by the Hebrew priesthood as they are at this day; but copies were likewise accessible to the early Christians, and by these pious apostles and disciples they were treasured as the prophetic testimony of God's eternal design for the salvation of mankind, in the grand event which had now actually occurred—the coming of Jesus Christ.

When the books of the New Testament were collected and authenticated by the early fathers and other members of the Christian church, they were held in equal esteem with those of the Old, and carefully preserved along with them. Though still in detached manuscripts, they were generally in the Greek tongue; but, during the first three centuries of our era, Latin, or the language of the Romans, came largely into use in literature, and, in the same manner as the modern European languages in later times superseded the Latin, so did the Latin supersede the Greek. Augustine (born 354—died 430) mentions that, previous to his time, there existed a great number of Latin versions of the Scriptural writings. "We know those who translated the Scriptures into Greek," says he, "and the number of them is not great; but the number of the Latin translators is infinite. When the faith came to be established, the first man who found a Greek copy, notwithstanding the little knowledge he had of the two languages, boldly undertook a translation of it." From another passage of his writings it has been generally concluded that there was one particular version, called "the Italian," in higher estimation than the rest, and which was the authorised version of the Roman churches. However this may be, it is certain that the Latin church required a version of the Scriptures formed directly from the Hebrew, as all the Latin translations in existence at that time had been taken from the SEVENTY. Jerome, who was the contemporary of Augustine, was in every respect best suited, of any of the learned men of that time, to the task of effecting a new translation, which he accordingly undertook. He began by correcting some books of the Old Testament in the Latin Bible, particularly the version of the Psalms, and marked those passages wherein any difference existed between the Latin version, the Greek of the Seventy, and the Hebrew original. He had early applied himself to the study of the Hebrew language, and at different periods had the assistance of five Jewish teachers; he had access, also, to the works of Origen, who published what is called the *Hexapla*, that is, the Bible in six different languages. From these he must have derived considerable assistance in the work he undertook—that of translating into Latin all the books of the Old Testament, to which he added a corrected edition of the common version of the New.

The work thus ascribed to Jerome (or St Jerome, as he is ordinarily called), received the name of the *Vulgate*, and both by Christians and Jews has been considered a faithful translation. It was sanctioned

* Edinburgh Encyclopædia, article CHRISTIANITY.

by the Council of Trent, since which time corrected editions have been published under the authority of the Popes Sixtus V. and Clement VIII. By the Roman Catholic body it is held in the highest esteem, and is reckoned equivalent in value to the Scriptures in the original tongues.

This seems to us the most proper place to notice—what must be clear to every one's comprehension—that, for the safe custody and verification of the Scriptures, from the period at which the New Testament books were collected, we are indebted to the Church, or, to speak more plainly, that series of ecclesiastical functionaries whose history is extended from the apostolic times till the present. Until the Bible, therefore, was secured to the people by the greatest of all mechanical applications, the art of printing, and in that respect placed beyond the reach of private interpolation or error, its safety, as a record, was dependent on the care and affection of the church, and for the faithful performance of that important service, no one surely will refuse a due meed of thankfulness and praise. From motives no doubt conscientious, many who have now the Bible in their hands may consider the Church a valueless institution; but to this incorporation are they unquestionably indebted for preserving the Scriptures through ages of persecution and civil uproar. From the era of Augustine and Jerome, when copies of the sacred books came into considerably greater request by the scattered branches of the Church, transcripts were effected by priests and latterly by monks, with a diligence and accuracy which demand our utmost esteem and approbation. In the cells of monasteries, surrounded by hordes of barbarous nobles and their serfs, learning found refuge from oppression; and there, in the darkest ages of European history, were humble and pious ecclesiastics engaged, certainly from no worldly consideration, in penning copy after copy of the Sacred Writings, and bequeathing them as memorials of their industry to future and more fortunate generations.

Both before and after the application of printing to multiply copies of the Bible, translations, either direct from the original tongues or from the Greek versions, were effected by almost every people to whom Christianity was introduced. Thus, copies of the Scriptures in Arabic, Persian, Slavonic, and other tongues, were produced. One of the most ancient of these is that translated for the use of the Armenian Christians in the fifth or sixth century.* Portions of the Scriptures are understood to have been translated into Anglo-Saxon, for use in the first British churches, as early as the

sixth or seventh centuries; and the whole Bible was translated by Bede, an eminent Romish ecclesiastic, in the beginning of the eighth century. The first English Bible we read of was that translated by Wickliffe, one of the earliest English reformers, about the year 1360, but never printed. The part of the English Bible first printed was the New Testament, translated by William Tindal, assisted by Miles Coverdale; it was printed abroad in 1526, but, giving offence to the church, was bought up and burnt. "In 1532, Tindal and his associates finished the whole Bible except the Apocrypha, and printed it abroad: but while he was afterwards preparing for a second edition, he was taken up and burnt for heresy in Flanders. On Tindal's death, his work was carried on by Coverdale, and John Rogers, superintendent of an English church in Germany, and the first martyr in the reign of Queen Mary, who translated the Apocrypha, and revised Tindal's translation, comparing it with the Hebrew, Greek, Latin, and German, and adding prefaces and notes from Luther's Bible. He dedicated the whole to Henry VIII. in 1537, under the borrowed name of Thomas Matthews; whence this has been usually called *Matthew's Bible*. It was printed at Hamburg, and licence obtained for publishing it in England by the favour of Archbishop Crammer and the Bishops Latimer and Shaxton. The first Bible printed by authority in England, and publicly set up in churches, was the same Tindal's version, revised, compared with the Hebrew, and in many places amended, by Miles Coverdale, afterwards Bishop of Exeter, and examined after him by Archbishop Crammer, who added a preface to it; whence this was called *Crammer's Bible*. It was printed by Grafton, was of large size, and published in 1540; and, by a royal proclamation, every parish was obliged to set one of the copies in its church, under the penalty of forty shillings a-month; yet, two years after, the bishops obtained its suppression by the king. It was restored under Edward VI., suppressed again under Queen Mary, and restored again in the first year of Queen Elizabeth, and a new edition of it given in 1562. Some English exiles at Geneva in Queen Mary's reign, namely, Coverdale, Goodman, Gilbie, Sampson, Cole, Whittingham, and Knox, effected a new translation, printed there in 1560—the New Testament having been printed in 1557—hence called the *Geneva Bible*; containing the variations of readings, marginal annotations, &c., on account of which it was much valued by the Puritan party in that and the following reigns. Archbishop Parker resolved on a new translation for the public use of the church, and engaged the bishops and other learned men to take each a share or portion. These being afterwards joined together, and printed with short annotations in 1568, in large folio, made what was afterwards called the *Great English Bible*, and commonly, the *Bishop's Bible*. In 1589, it was also published in octavo, in a small but fine black letter: and here the chapters were divided into verses; but without any breaks for them, in which the method of the Geneva Bible was followed, which was the first English Bible where any distinction of verses was made. It was afterwards printed in large folio, with corrections, and several prolegomena, in 1572: this is called *Matthew Parker's Bible*. The initial letters of each translator's name were put at the end of his part. The archbishop oversaw, directed, examined, and finished the whole. This translation was used in the churches for forty years, though the Geneva Bible was more read in private houses, being printed above twenty times in as many years."

Various editions of the Bishop's Bible were printed at London in black letter at the beginning of the seventeenth century; but notwithstanding the care that had been expended on it, the version was not very correct, and its language was often far from elegant. To amend these deficiencies, and to obtain a really excellent version, James I. ordered an entirely new translation, which is that now in common use throughout Great Britain. To effect this very important undertaking, forty-seven distinguished scholars were appointed, and

* "For the more commodious comparison of different versions, many of them have been sometimes joined together. In his eightfold Bible, Origen placed, in different columns, a Hebrew copy, both in Hebrew and in Greek characters, with six different Greek versions. Elias Hutter, a German, about the sixteenth century, published the New Testament in twelve languages, namely, in Greek, Hebrew, Syriac, Latin, Italian, Spanish, French, German, Bohemian, English, Danish, Polish; and the whole Bible in Hebrew, Chaldaic, Greek, Latin, German, and a varied version. But the most esteemed collections are those in which the originals and ancient translations are conjoined, such as the Complutensian Bible, by Cardinal Ximenes, a Spaniard; the King of Spain's Bible, directed by Montanus, &c.; the Paris Bible, by Michael Jay, a French gentleman, in ten large folio volumes, copies of which were published in Holland, under the name [or sanction] of Pope Alexander VII.; and that of Brian Walton, afterwards Bishop of Chester. This last is the most regular and valuable: it contains the Hebrew and Greek originals, with Montanus's interlineary version; the Chaldee paraphrases, the Septuagint, the Samaritan Pentateuch, the Syriac and Arabic Bibles, the Persian Pentateuch and Gospels, the Ethiopic Psalms, Song of Solomon, and New Testament, with their respective Latin translations; together with the Latin Vulgate, and a large volume of various readings, to which is ordinarily joined Castel's Heptaglot Lexicon—all included in eight volumes folio."—*Brown's Dictionary of the Bible*.

Biblical scholars are now greatly assisted in their studies by the publication of poly-glott editions of the Bible, containing in parallel columns versions in various ancient and modern languages. The word *poly-glott* signifies many tongues.

divided into six classes. Ten at Westminster were to translate to the end of 2d Kings; eight at Cambridge were to finish the remaining historical books and the Hagiographa; at Oxford, seven were engaged on the Prophets, eight upon the four Gospels, the Acts of the Apostles, and the Apocalypse: the Apocryphal books were to be translated at Cambridge. Each individual translated all the books allotted to his class; the whole class then compared all the translations, and adopted the readings agreed on by the majority. The book, thus finished, was sent to each of the other classes. Three years were consumed in this arduous duty of translating and examining. Copies were then sent to London, one from each of the above-named places. Here a committee of six, one from each class, reviewed the whole, which was last of all revised by Doctor Smith, and Doctor Bilson, Bishop of Winchester. Having received the approbation of the king, himself no mean scholar, it was printed in 1611. We are not informed by any writer, whether the translation was effected from Hebrew copies of the Old Testament or the Greek Septuagint, or whether any transcriptions of the original manuscripts were consulted;* but it is allowed by all persons competent to judge, that the version possesses extraordinary merit, and is the most perfect ever produced.

CHRISTIANITY.—HISTORY OF THE CHURCH.

Early History.

At the period of Christ's appearance on earth,† the land of Judea had sunk to the condition of a Roman province, and its people, the Jews, were in a condition not only of civil but great moral degradation. Their religion, as appears from all history, had degenerated from its ancient and lofty character, and existed only as a system of empty external observances in the hands of a priesthood to the last degree corrupt. The leaders of the people, and the chief priests, according to the account of Josephus, were persons of profligate manners, who had purchased their places by bribes or by acts of iniquity, and who maintained their authority, in subordination to the Roman civil power, by flagitious crimes. The multitude, affected by the example of their superiors, were not less corrupted in morals; and in a general sense it may be understood that the entire nation was in a state of lamentable disorder. To aggravate the distractions of the people, they were divided into a variety of sects, who, in proportion as they neglected the essentials of religious faith and practice, occupied themselves in disputes respecting matters of inferior concern. Of these sects, three in a great measure eclipsed the rest, both by the number of their adherents, and also by the weight and authority which they acquired: these were the Pharisees, the Sadducees, and the Essenes. The chief difference of opinion among these leading sects regarded the interpretation to be put on the words in the Holy Scriptures; and none of them seemed to have the interests of true piety at heart. The best of the three was the Essenes, who discountenanced ostentation in religious offices, and inclined to lives of secluded meditation. While the Jews, then, were thus broken up into contending sects, and were apparently in a state of profound ignorance of the true principles of religion, Jesus Christ appeared amongst them, to execute his divine mission, which referred not only to them but the whole human race. In the writings of the Evangelists we are furnished with so remarkably precise an account of the birth and public ministrations

of Christ, as also of his death and passion, as to leave nothing to be said here on the subject; and we pass on to an enunciation of the principles which it was the object of his mission to accomplish, and an historical sketch of that universal society of believers, the Church, which he empowered to work out his designs.

Supposing Christianity, or the religion of Christ, to be reducible to a single principle, it might be described as an universal truth adapted to all mankind, and of a divine, all-uniting power—a principle of love and universal brotherhood, without respect of nation, age, rank, colour of skin, or any other exterior circumstance; in short, a system of faith and practice for the whole human race. A religion to be so universally applicable should necessarily embrace no tenet or observance which required special localisation. Judaism required a periodic visitation to the Temple at Jerusalem; Mahometanism requires the performance of pilgrimages to certain cities in Arabia, also attention to forms only suitable to the daily and seasonal influences of a warm climate; Hindooism enjoins constant ablutions in the Ganges, besides other local observances—all which mark these religions as but referable to certain nations and countries, and not compatible with modes of existence in all parts of the earth. Setting aside, for the present, all other considerations, Christianity, by including no obligation which could not be as well performed in one part of the globe as another, or as well in one age as another, is something very different from religions either temporary or local in their character. In this universal and eternal applicability, then, do we find one of the grandest features of the religion of Christ.

The promulgation of the principle of universal benevolence and love—the antagonism of every evil or violent emotion—was, whatever may be said of it, new to the Jewish people. True, they believed in one God, the Creator of all things, and so far had just views of the Source of religion; they also possessed the commandments of the Mosaic law; but when, on any occasion, did they view the Gentile nations, or foreigners, in any other light than as an inferior race of mankind, to whom their laws and usages had no sort of applicability? Practically, their religion narrowed the affections, while Christianity was all for widening them. "The Greeks, besides developing the principle of the beautiful in their works of art, had laid the foundations of valuable sciences applicable to the business of life. The Romans had established the principles of law and political administration, and proved their value by experience. These scattered elements of moral and intellectual cultivation, insufficient, in their disunited state, to bring about the true happiness and moral perfection of man, in his social and individual capacity, were refined, perfected, and combined, by Christianity, through the law of a pure benevolence, the highest aim of which is that of rendering men good and happy, like God, and which finds, in the idea of a kingdom of heaven upon earth, announced and realised by Christ, all the means of executing its design. His religion supplied what was wanting in these nations—a religious character to the science of Greece, moral elevation to the legislative spirit of Rome, liberty and light to the devotion of the Jews; and by inculcating the precept of universal love of mankind, raised the narrow spirit of patriotism to the extended feeling of general philanthropy. Thus, the endeavours of ancient times after moral perfection were directed and concentrated by Christianity, which supplied at the same time a motive for diffusing more widely that light and those advantages which mystery and the spirit of caste had formerly withheld from the multitude. It conveyed the highest ideas, the most important truths and principles, the purest laws of moral life, to all ranks; it proved the possibility of perfect virtue, through the example of its Founder; it laid the foundation for the peace of the world, through the doctrine of the reconciliation of men with God and with each other; and, directing their minds and hearts towards Jesus, the Author and Finisher of their faith,

* The most ancient manuscripts of the Bible, in the original Hebrew, are to be found among the Jews in Spain (or were so some years ago), but none of them is above seven or eight hundred years old: a manuscript in the Bodleian Library at Oxford is thought to be seven hundred years old; in the library of the Vatican at Rome there are manuscripts, we believe, of parts of the Old and New Testament, which are of considerable antiquity. The first edition of the entire Hebrew Bible was printed at Soncino in 1488; and the Brescian edition of 1494 was used by Luther in making his German translation.

† The term *Christ* is from the Greek, and signifies "the Anointed;" *Messiah*, from the Hebrew, has the same meaning.

the crucified, arisen, and glorified Mediator between heaven and earth, it taught them to discern the benevolent connexion of the future life with the present.”*

Systems of chronology differ with regard to the age of the crucifixion of the Saviour, some placing it in A.D. 30, and others in A.D. 33. In either case, as is known to the readers of the evangelical history, the apostles and disciples who had followed him while on earth began, shortly after his departure, those ministrations which they were commissioned to execute by their divine Master, and which had for their object the dissemination of the Gospel in all parts of the world. It will be further recollected, that, in consequence of the defection and death of the traitor Judas, the apostles were reduced to eleven in number—Peter, and Andrew his brother; James the son of Zebedee, and John his brother; Philip and Bartholomew; Thomas and Matthew; James the son of Alphaeus, and Jude his brother; lastly, Simon the Canaanite. Afterwards, they elected Matthias in place of Judas. The number, however, was again reduced to eleven, by the murder of James, the brother of John, by Herod (A.D. 44).

The first society or church established by the apostles was at Jerusalem; and, from all that can be learned, it was on the most simple and unpretending scale, corresponding to the nature of the religion which they professed. One of Christ's most emphatic declarations had been that “his kingdom was not of this world,” by which he signified that the Christian doctrines and graces referred exclusively to the mental affections, were a business of the heart, not of outward show or demonstration, and had in other respects no alliance with civil dominion. The humble but intrepid apostles, therefore, in the course of their preaching and teaching in Judea, and afterwards in other countries, took no part in any design to subvert temporal governments, or to bring them into contempt; neither did they seek to ally themselves with civil rulers, but confined themselves in all places to their proper functions of calling sinners to be converted to the faith of Jesus, comforting those who mourned, animating the piety of the dejected, and, in particular, assisting the poor and needy. Of the forms of Christian worship in this infant state of the Church, little is known; and, indeed, it appears that some time elapsed before the converted, or at least the pupils to the apostolic teachers, forsook the forms enjoined in the old Judaic mode of worship. According to Mosheim, they “held separate assemblies, in which they were instructed by the apostles and elders, prayed together, celebrated the holy supper in remembrance of Christ, of his death and sufferings, and the salvation offered to mankind through him; and at the conclusion of these meetings, they testified their mutual love, partly by their liberality to the poor, and partly by sober and friendly repasts, which thence were called *feasts of charity*. Among the virtues which distinguished the rising church in this its infancy, that of beneficence to the poor and needy shone in the first rank and with the brightest lustre. Having finished their work at Jerusalem, the apostles proceeded to other nations, and travelled over a great part of the known world, in a short time planting a vast number of churches among the Gentiles. Several of these are mentioned in the sacred writings, particularly in the *Acts of the Apostles*, though these are undoubtedly but a small part of the churches which were founded, either by the apostles themselves or by their disciples under their immediate direction.”

It is not our design to enter into a formal detail of what constituted the various points of belief and religious practice in this early age of the Church. It will be understood that there was at first no body of written evidence answering as a fountain of doctrine and precept, such as we now possess in the collected books of the New Testament; and that apostles, and those who were raised up to assist them in their holy cause, were accordingly thrown much more on their own re-

sources, and more dependent on God's inspiring power to teach and direct, than required to be the case in more advanced times. To use the words of Mosheim—“Among the first professors of Christianity there were but few men of learning; few who had capacity enough to insinuate into the minds of a gross and ignorant multitude the knowledge of divine things. God, therefore, in his infinite wisdom, judged it necessary to raise up, in many churches, extraordinary teachers, who were to discourse in the public assemblies upon the various points of the Christian doctrine, and to treat with the people, in the name of God, as guided by his direction, and clothed with his authority. Such were the *prophets* of the New Testament.”—(Rom. xiii. 6; 1st Cor. xii. 28; xiv. 3-29; and Eph. iv. 11.)

Much as we desire to do so, it is impossible for us to pass over a circumstance in the history of these early times, which has led to centuries of discord; we allude to the early form of church government. We shall allow a place to Mosheim's explanations on this subject. “Neither Christ himself, nor his holy apostles, have commanded any thing clearly or expressly concerning the external form of the Church, and the precise method according to which it should be governed. From this we may infer, that the regulation of this was, in some measure, to be accommodated to the time, and left to the wisdom and prudence of the chief rulers, both of the state and of the Church. If, however, it is true that the apostles acted by divine inspiration, and in conformity with the commands of their blessed Master (and this no Christian can call in question), then it follows, that that form of government which the primitive churches borrowed from that of Jerusalem, the first Christian assembly established by the apostles themselves, must be esteemed as of divine institution. But from this it would be wrong to conclude that such a form is immutable, and ought to be invariably observed; for this a great variety of events may render impossible. In those early times, every Christian church consisted of the *people*, their *leaders*, and the *ministers*, or *deacons*; and these, indeed, belong essentially to every religious society. The people were, undoubtedly, the first in authority; for the apostles showed, by their own example, that nothing of moment was to be carried on or determined without the consent of the assembly, and such a method of proceeding was both prudent and necessary in those critical times.

It was, therefore, the assembly of the people which chose their own rulers and teachers, or received them by a free and authoritative consent, when recommended by others. The same people rejected or confirmed by their suffrages the laws that were proposed by their rulers to the assembly, excommunicated profligate and unworthy members of the church, restored the penitent to their forfeited privileges, passed judgment upon the different subjects of controversy and dissension that arose in their community, examined and decided the disputes which happened between the elders and deacons, and, in a word, exercised all that authority which belongs to such as are invested with the sovereign power. The people, indeed, had in some measure purchased these privileges, by administering to the support of their rulers, ministers, and poor, and by offering large and generous contributions, when the safety or interests of the community rendered them necessary. In these supplies, each one bore a part proportioned to his circumstances, and the various gifts which were thus brought into the public assemblies were called *oblations*.

The rulers of the church were called either *presbyters* or *bishops*, which two titles are, in the New Testament, undoubtedly applied to the same order of men. These were persons of eminent gravity, and such as had distinguished themselves by their superior sanctity and merit. Their particular functions were not always the same; for while some of them confined their labours to the instruction of the people, others contributed in different ways to the edification of the church. Hence the distinction between *teaching* and *ruling presbyters*

* Encyclopædia Americana, article CHRISTIANITY.

has been adopted by certain learned men. But if ever this distinction existed, which I neither affirm nor deny, it certainly did not continue long; since it is manifest that St Paul requires that all bishops or presbyters be qualified and ready to teach and instruct.

The Church was, undoubtedly, provided from the beginning with inferior ministers or *deacons*. No society can be without its servants, and still less such societies as those of the first Christians were. And it appears not only probable, but evident, that the *young men*, who carried away the dead bodies of Ananias and Sapphira, were the subordinate ministers, or *deacons* of the Church of Jerusalem, who attended the apostles to execute their orders. All the other Christian churches followed the example of that of Jerusalem in whatever related to the choice and office of the deacons.

Such was the constitution of the Christian Church in its infancy, when its assemblies were neither numerous nor splendid. Three or four presbyters, men of remarkable piety and wisdom, ruled these small congregations in perfect harmony, nor did they stand in need of any president or superior to maintain concord and order where no dissensions were known. But the number of the presbyters and deacons increasing with that of the churches, and the sacred work of the ministry growing more painful and weighty by a number of additional duties, these new circumstances required new regulations. It was then judged necessary that one man of distinguished gravity and wisdom should preside in the council of presbyters, in order to distribute among his colleagues their several tasks, and to be a centre of union to the whole society. This person was at first styled the *angel* of the church to which he belonged, but was afterwards distinguished by the name of *bishop*, or *inspector*; a name borrowed from the Greek language, and expressing the principal part of the episcopal function, which was to inspect and superintend the affairs of the church. It is highly probable that the Church of Jerusalem, grown considerably numerous, and deprived of the ministry of the apostles, who were gone to instruct the other nations, was the first which chose a president or bishop. And it is no less probable that the other churches followed by degrees such a respectable example. * * * A bishop, during the first and second century, was a person who had the care of one Christian assembly, which at that time was, generally speaking, small enough to be contained in a private house. In this assembly he acted, not so much with the authority of a *master*, as with the zeal and diligence of a faithful *servant*. He instructed the people, performed the several parts of divine worship, attended the sick, and inquired into the circumstances and supplies of the poor. He charged, indeed, the presbyters with the performance of those duties and services which the multiplicity of his engagements rendered it impossible for him to fulfil; but had not the power to decide or enact any thing without the consent of the presbyters and people. And though the episcopal office was both laborious and singularly dangerous, yet its revenues were extremely small, since the church had no certain income, but depended on the gifts or oblations of the multitude, which were, no doubt, inconsiderable, and were, moreover, to be divided between the bishops, presbyters, deacons, and poor.

The power and jurisdiction of the bishops were not long confined to these narrow limits, but soon extended themselves, and that by the following means. The bishops who lived in the cities, had, either by their own ministry or that of their presbyters, erected new churches in the neighbouring towns and villages. These churches, continuing under the inspection and ministry of the bishops by whose labours and counsels they had been engaged to embrace the gospel, grew imperceptibly into ecclesiastical provinces, which the Greeks afterwards called *dioceses*. But as the bishop of the city could not extend his labours and inspection to all these churches in the country and in the villages, so he appointed certain suffragans or deputies to govern and to instruct these new societies; and they were dis-

tinguished by the title of *chorepiscopi*, that is, country bishops. This order held the middle rank between bishops and presbyters, being inferior to the former and superior to the latter.

The churches in those early times were entirely independent; none of them subject to any foreign jurisdiction, but each one governed by its own rulers and its own laws. For, though the churches founded by the apostles had this particular deference shown them, that they were consulted in difficult and doubtful cases, yet they had no juridical authority, no sort of supremacy over the others, nor the least right to enact laws for them. Nothing, on the contrary, is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear in this first century the smallest trace of that association of provincial churches, from which *councils* and *metropolitans* derive their origin. It was only in the second century that the custom of holding councils commenced in Greece, from whence it soon spread through the other provinces."

According to these explanations, it would appear that the earliest constitution of the church was exceedingly simple, being in a great measure a confederacy of separate and independent religious instructors; that it gradually assumed the external features of Presbyterianism (equality of rank, but mutual jurisdiction); and that, finally, as Christianity spread, and the scattered societies of believers required the supervision and counsel of superiors, there arose a species of Episcopacy or superintendence by apostolic bishops. According to others, the bishops exercised a superintendence from the first, the earliest being the apostles; and it is reasonable to suppose that some such superior directors, exercising an authority in a spirit of perfect love, must have been necessary for the sake of order and uniformity of doctrine; it is at the same time certain that, whether in the capacity of equals or superiors, the apostles and early bishops performed the office of ordinary teachers of religion. The commissioning of ministers of the gospel by ordination, or the symbol of laying on of hands, appears to have existed from the earliest ages of Christianity. The members of the church at Antioch, founded by Paul and Barnabas, were the first who received the name of *Christians*, having been previously called Nazarenes, by way of derision.

From about the conclusion of the first till the sixth century, there flourished a body of eminent men in connexion with the Church, whose functions may be said to have generally united those of a professor of divinity and ethics with the pastoral office. These are known in Church History by the title of *Fathers*. They were of two chief classes—Greek and Latin fathers—and were alike distinguished for their erudition. The most celebrated among the Greek fathers was Clement of Alexandria (beginning of the second century), who was the first who philosophised on Christianity; Origen, at one time a pupil of Clement, celebrated for his homilies and writings illustrative of the Scriptures; Eusebius, who wrote the first history of Christianity; Athanasius (296–373), Bishop of Alexandria, and a man of invincible courage under persecutions, whose writings exerted a considerable influence on the Christian dogmas; and Chrysostom (344–407), an ascetic, the most admired of the ancient orators. The most distinguished among the Latin fathers were—Tertullian, born about the middle of the second century, and a writer of great originality; Augustine (354–430), a man of persuasive eloquence, exalted piety, and a warm encourager of the monastic life; Ambrose (340–397), Bishop of Milan, an eminent orator, and famed for his mild and humane character; and Jerome (331–420), one of the most learned writers and able expounders of the Scriptures, which, as formerly mentioned, he translated into the Latin tongue.

In the course of the second and third centuries, the history of the Church is painfully disfigured by the assumption of dominant powers by bishops; the division

of the clergy into subordinate ranks and offices; the increase of ceremonial observances, fasts, and festivals; and, above all, differences of opinion among Christians on matters of belief. One main cause of the variety of opinion might be traced to the collateral influence of the Grecian philosophies, particularly that of Plato. Many converts had been educated in these philosophies, and though Christianised, they still retained the subtle speculative notions implanted in their minds, as well as divers Pagan usages. From disputing in the schools of Athens on questions in metaphysics, they betook themselves to controversies on the most abstruse points of theology. From controversy, the disputants naturally subsided into heresy and schism; and hence we find that, while the Christian Church was on all sides struggling against barbarous powers, it was itself torn by intestine division. In this general sketch, we can only mention that the leading sectaries at this period were the Manicheans, Hieracites, Sabellians, and Novatians; and in the fourth century the heresy of Arius broke out, and produced incalculable injury. Prior to this latter event, the external condition of the Church underwent an entire change.

For nearly three hundred years after the death of Christ, the Church, though gradually altering in internal organisation, doctrinal belief, and ritual observance, was still an independent spiritual community, reposing on the simple but glorious basis on which it had been placed by its Divine Author, and in which condition it may be said to have been invulnerable. The conversion of Constantine the Roman Emperor, in 321,* at once altered the primitive state of the Church. "Before that important period, some churches had been liberally supported by the devotion and zeal of wealthy individuals; but yet the situation of the clergy was insecure and contemptible in the eyes of the Pagan world. Afterwards, they lived in princely splendour, honoured and esteemed as the first rank of men in the empire. Formerly, they had been sunk in the gloom of obscurity, but now they basked in the broad sunshine of honour, wealth, and imperial favour. To a person who contemplates the aspect of the Roman empire in that age, a new world seems to appear. The system of polytheism and idol worship, which, from time immemorial, had, by its pompous ceremonies and splendid festivals, commanded the veneration of mankind, fell into disrepute; and Christianity, which had so long been the object of universal contempt, and frequently of cruel persecution, at last triumphed over all opposition, and became the established religion of the masters of the world. The Roman empire saw magnificent churches erected for the worship of the crucified God, whose name had been long despised, and the rites of the Christian religion celebrated with a pomp and solemnity equal, if not superior, to what had been displayed in the Pagan temples. A total revolution was taking place in the texture of religious opinions and the combinations of human ideas. What a scene would this have appeared to a Christian of the apostolic age, or of that which immediately succeeded it! What would a Christian whose mind had been formed, whose religious ideas had been modelled, by the simple and disinterested maxims of primitive Christianity, think, on seeing the ministers of the humble and lowly Jesus display the magnificence of sovereign princes! And what must have been his reflections on contemplating a system of honour and emolument, set-up by the professed followers of one whose whole life was a continued scene of poverty and sufferings, and whose preaching and practice were entirely calculated to inspire all those who embraced his doctrine with a sovereign contempt for the things of this world! In the reign of Constantine the Church was enriched; but it evidently appears that the spirit of genuine Christianity was in a great measure extinguished. Ecclesiastical history, which had hitherto exhibited a horrible and sanguinary scene of the sufferings of the Church under Pagan persecutors, then

began to display a not less disgusting view of the persecution of Christians by the hand of Christians, carried on with a cruelty little short, in some instances, of that which Pagans had before exercised against them."*

To extinguish, as far as possible, the heresy of Arius, and allay other causes of schism, Constantine convoked the celebrated Council of Nice (325), which consisted of 318 bishops, and other ecclesiastics to the number of 2048. After a session of two months, in which the emperor frequently assisted in person, the opinions of Arius, which went to a denial of the divinity of Christ, were condemned, the equality of the three Persons of the Holy and Undivided Trinity was declared the true doctrine, and, being comprised in a form of belief called the Nicene Creed, was published as the obligatory and only orthodox creed of the Christian Church.†

The deliberations of the Council of Nice failed in their main design, and the Arians, persecuted by the Church, dispersed themselves in distant nations, and there found a safe retreat. This may be viewed as the first great schism in the Church, which henceforth consisted, not in one, but in several distinct societies of believers. To trace minutely the progress of the respective branching-off communions, would lead us considerably beyond our limits; let it suffice to say, that in the fourth and fifth centuries, there were founded several important eastern churches. The Armenian Church dates its commencement from about the year 312. The Egyptian or Coptic Church originated in a heresy in the fourth century; and the Abyssinian Church shortly after branched off from it. The Syrian Church, in a similar manner, gave origin to the Syro-Indian Church, which still exists in Travancore and Cochin, and acknowledges as its head the Patriarch of Antioch. It is likewise to the fourth century that we must trace the origin of that great schism which afterwards divided the Church into the Western or Roman Church, and the Eastern or Greek Church. At this period, the Bishop of Rome occupied the first rank in the episcopal order, and on that account exerted a certain authority over all other bishops within the pale of the orthodox Church. "Constantine, by removing the seat of empire to Byzantium (Constantinople), raised up in the bishop of this new metropolis a formidable rival to the Roman pontiff. Accordingly, in a council held at Constantinople, in the year 381, by the authority of Theodosius the Great, the bishop of that city was, during the absence of the Bishop of Alexandria, and against the consent of the Roman prelate, placed in the first rank after the Bishop of Rome, and

* Bigland's Letters on History.

† The Nicene Creed, after receiving some subsequent additions, stood as follows, and has for ages occupied a place in the Church service:—"I believe in one God, the Father Almighty, Maker of heaven and earth, and of all things visible and invisible; and in one Lord Jesus Christ, the only begotten Son of God, begotten of his Father before all worlds; God of God, Light of Light, Very God of Very God, being of one substance with the Father, by whom all things were made; who for us men, and for our salvation, came down from heaven, and was incarnate by the Holy Ghost of the Virgin Mary, and was made man, and was crucified also for us under Pontius Pilate: He suffered and was buried, and the third day he rose again according to the Scriptures, and ascended into heaven, and sitteth on the right hand of the Father, and he shall come again with glory to judge both the quick and the dead; whose kingdom shall have no end: And I believe in the Holy Ghost, the Lord and Giver of Life, who proceedeth from the Father and the Son, who with the Father and the Son together is worshipped and glorified, who spake by the Prophets: And I believe one Catholic and Apostolic church; I acknowledge one baptism for the remission of sins; and I look for the resurrection of the dead, and the life of the world to come. Amen."

With respect to the form of belief usually called the Apostles' Creed, it is believed to be of much less antiquity than the apostolic age, but there is great obscurity as to its authorship. It also has undergone alterations in the course of time. "The third creed, erroneously ascribed to Athanasius (who assisted at the Council of Nice in 325), is affirmed to have been privately drawn up about the middle of the fourth century; and is rejected by all the Protestant churches except the Anglican."—*Conder's View of all Religions.*

* See HISTORY OF GREECE AND ROME in the present series.

consequently above those of Alexandria and Antioch."—(*Mosheim*). The rivalry and contentions of the bishops of Rome and Constantinople which ensued from this period, terminated in 1054 in a complete rupture. Each power excommunicated the other, and henceforth the Greek Church was entirely under the authority of the Patriarch of Constantinople. The other branch of the Church remained under the dominion of the Roman pontiff, and is that which is known by the name of the Roman Catholic Church.

Centuries before this latter event, the Church, under the generally recognised supremacy of the Bishop of Rome, had undergone the most extraordinary changes of condition. The legal establishment of Christianity as the religion of the state, and its consequent alliance with civil power, gave it a new character. That this authoritative recognition greatly aided in converting the pagan world, there can be no manner of doubt; but unfortunately, as we have seen, the wealth and authority conferred on churchmen naturally introduced evils gross in their nature; and in many respects the alliance with the civil government did infinitely more harm than good. Some writers aver that Christianity could scarcely have survived the dismemberment of the Roman empire and the barbarism that ensued throughout the middle ages, unless fortified by civil power; but this, we humbly submit, is but a timid view of the Christian dispensation, which surely required no such extraneous means of support. It is a lamentable truth, confirmed by every respectable historian, that the proceedings of Constantine (321), and afterwards of Theodosius (380), in establishing Christianity as the religion of the empire, laid the foundation of every species of ecclesiastical abuse, and directly caused the decay of that sublime but simple piety which was the ornament of the apostolic times. It is to the arrangements consequent on the alliance of the Church with the civil power, that we have also to trace the origin of that new feature in ecclesiastical polity, the endowment of churches, cathedrals, abbeys, monasteries, and other institutions, with the functionaries belonging to them. But the most extraordinary change, both in the internal and external character of the Church, was the excess of power which, by the sanction of temporal princes, was accorded to the bishops of Rome. From early times, the occupant of the Roman primacy had been known under the title of *papas*, a Greek word signifying father, and hence the well-known terms, *papal* and *pope*. The pope, aided by his council, formed the head of the hierarchy, and acted as a supreme magistrate in all religious matters whatsoever. From the possession of the spiritual supremacy, a plea was easily found to assume the right of interfering in temporal concerns; and, as is known to the readers of history, the pope was allowed to exercise an almost unquestioned authority over the affairs of Christian princes for several centuries. It is at the same time proper to remark, that the lay and clerical members of the Church did not always agree in conceding this excessive power to the popes; the right of spiritual jurisdiction was not denied, but how far, and in what manner, that of a temporal nature, without the express sanction of general councils, should be allowed, formed a point of frequent debate, and we do not know that Catholics have yet arrived at an uniformity of opinion on the subject.

Another serious abuse which crept into the ecclesiastical affairs of the Church, was the establishment of monastic institutions—houses in which men secluded themselves from the world, and engaged themselves in religious offices. The practice of living as hermits, for the purpose of religious meditation, existed before Christianity, and was only engrafted upon it (in a regular manner) about the beginning of the fourth century; and in the course of the following hundred years, monasteries greatly increased in number. In the sixth century, the practice of taking vows of celibacy and rigid adherence to certain rules, was introduced by St Benedict; from which period till the tenth century, monasteries are generally allowed to have been dwellings of piety,

temperance, and the refuge of learning, driven to them for shelter from the troubles of the times. In the course of the tenth and eleventh centuries, the monasteries lost this valuable character. Idleness and luxury entered their walls, together with the vices of the world; their superiors, named abbots or priors, appointed by lay princes from among the nobility, set themselves above the jurisdiction of the bishops; and, in short, the whole monastic system, including convents for female devotees (nuns), became altogether corrupt. None of the religious orders rose to such eminence and power as the Society of Jesus, or Jesuits, founded by Ignatius Loyola (1491–1556), a Spaniard, and a man of great shrewdness and enthusiasm. The society was sanctioned by a bull (or ordinance) of Paul III. in 1560. Young men of ability and peculiar energy of character were alone admitted, and the trials of the novices were most severe. In addition to the usual vows of poverty, chastity, and implicit obedience to superiors, the members were bound to go, unhesitatingly and without recompense, whithersoever the pope should send them, as missionaries for the conversion of pagans and heretics, or for the service of the Church in any other way. This well-trained and formidable corps of spiritual combatants long exerted a powerful influence throughout Christendom, as well as in heathen countries; but as general intelligence advanced, they failed in their efforts; in 1773 their order was abolished by Clement XIV.; and latterly (though restored in 1814) they sunk into comparative obscurity.

The many flagrant corruptions of the Church began to excite the attention of reflecting men in the fourteenth century, and efforts were on divers occasions made by them to produce a reform, but without success. The abuses chiefly complained of were the scandalous lives of many of the clergy, particularly of the monastic and mendicant orders, the gross superstitious reverence generally paid to relics, the extravagant power of the pope, and the sale of indulgences. The exhibition of religious relics, with the view of exciting the piety of believers, had degenerated into a system of pure imposture. "The poor fragments of mortality, a skull, a bone, or the fragment of a bone, a tooth, or a tongue, were either mounted or set, according to the size, in gold and silver, deposited in costliest shrines of the finest workmanship, and enriched with the most precious gems. Churches soon began to vie with each other in the number and variety of these imaginary treasures, which were sources of real wealth to their possessors. The instruments of our Lord's crucifixion were shown (the spear and the cross having, so it was pretended, been miraculously discovered), the clothes wherein he was wrapt in infancy, the manger in which he was laid, the vessels in which he converted water into wine at the marriage feast, the bread which he broke at the last supper, his vesture for which the soldiers cast lots. Such was the impudence of Romish fraud, that portions were produced of the burning bush, of the manna which fell in the wilderness, of Moses's rod and Samson's honeycomb, of Tobit's fish, of the blessed Virgin's milk, and of our Saviour's blood!"—(*Southey*).

The ludicrous extent to which the exhibition of relics was carried, and also the abstract claims of spiritual supremacy by the pope, might have been tolerated for some time longer; but the plenary power of selling immunities for transgressions roused the common sense of mankind. Leo X., famous for his love of splendour, commenced this odious traffic. Martin Luther (1483–1546), a monk of the order of Augustine, in Germany, was shocked with the effects of the system, as they appeared in his congregation at Wittenberg. "By far the most notable vender of indulgences was Tetzel, a Dominican, whose morals were on a par with his impudence. This man had popular talents: he was a ready, sonorous preacher; he was intimately acquainted with the human heart; and these advantages, joined to his dignity as prior of his order, pointed him out as the fittest person to sell these indulgences. He was accordingly made chief commissioner, and his success at the different towns he visited was prodigious.

From the pulpit he declared indulgences to be the most sublime of God's favours; they had saved more souls than the efforts of all the Apostles; they would atone for every sin, however heinous; they were effectual in regard to future, no less than past transgressions; they atoned for the dead no less than the living; and whoever suffered his relatives to remain in purgatory, when a little money would release them, was guilty of the worst crime. Hence a blow was struck at all repentance: contrition of heart was out of the question, when pardon could be obtained on terms so much easier. The present recital would perhaps be disbelieved, if its truth were not virtually admitted by contemporary Roman Catholics. But good is often educed from evil; and this preaching of indulgences was one of the chief causes of the Reformation. There is reason to believe that the whole system struck Luther with horror from the very first; and that, coupled with the impiety which he had witnessed in the capital of Christendom, it provoked his doubts as to the infallibility of the papal authority. The effects of the indulgences were every day before his eyes; and, as one of the authorised confessors of the people of Wittenberg, he perceived them more clearly than other men. While seated in the tribunal of penance, he was amazed to hear what crimes had been committed, and still more, that no contrition was felt for them. He refused to absolve, unless the criminals forsook their evil ways. They showed him their letters of impunity: no matter; he estimated these at their just value, namely, as so many pieces of waste paper. Being dismissed without absolution, and without admission to the sacraments, the deluded purchasers complained to Tetzel, who bellowed and threatened; but Luther was undaunted: he openly preached against the pernicious traffic; he attacked the very foundation on which it rested; he denied the power of pope or Church to remit the guilt of sin; and by his famous propositions, as every body knows, rapidly produced the most gigantic change effected in this world since the origin of Christianity.*

The preaching of Luther, in exposing the error of indulgences, and calling in question various traditional tenets and practices, speedily roused a large part of Germany; and as no symptom of relenting was shown on the part of those in power, an extensive secession from the Romish Church became unavoidable. The year 1521 is to be regarded as the epoch of the Reformation in Germany; and from this period it became a political as well as religious movement—in a word, a movement in favour of civil and religious freedom. In consequence of a general protest being signed by the reforming party against a decree of the Diet of Spire, in 1529, they received, in 1541, the name of *Protestants*. Eleven years earlier, in 1530, a declaration of the principles of the reformers, drawn up by Melancthon, was presented to the Emperor of Germany at a diet held at Augsburg, and there solemnly read before the assembly; this famous declaration is known in history as the Confession of Augsburg. The Reformation spread from country to country with singular rapidity: the ancient church was deposed, and one of a reformed character established in its place—in Switzerland and Geneva in 1535; in Sweden and Denmark in 1536; in England in 1547; and in Scotland in 1560. In Austria, Italy, Spain, Portugal, and France, the efforts of the reformers were less successful, and in these countries the Roman Catholic Church has been established, or at least popular, till the present day.

CONCLUDING SUMMARY.

Christianity now exists, in one or other of its various forms, in all civilised countries, and numbers, as is believed, 260,000,000, out of 900,000,000, the entire population of the globe. Although originating in Asia, and flourishing for some time in the adjacent regions of northern Africa (Church of Alexandria, for example),

it prevails only to a small extent in these continents, and is principally confined to Europe and the countries which have been peopled by European emigrants. Every where, it is the religion of *civilised man*, no other creed or form of belief being at all suitable to an advanced intelligence, or so directly calculated to inspire sentiments of refined piety, humanity, and justice. In the hands of uninstructed, ambitious, and intolerant men, its history abounds in the most odious crimes; but latterly, as its professors have fallen under the influence of a civilisation to which it has itself largely contributed, and as the true principles of the Gospel have been better understood, our religion has not been outraged by indecent excesses either at home or abroad; while, by the earnest but unostentatious efforts of its supporters, of various denominations, it has been made favourably known in the most remote parts of the earth.

The forms in which Christianity is professed are very numerous, but the whole are comprehended in three leading systems—the Roman Catholic Church, the Eastern Churches, and the Protestant or Reformed Churches.* With but one exception, all acknowledge

* *Roman Catholic Church.*—The doctrines and ritual of this body, as now professed, proximately rest in a great measure on the decisions of the Council of Trent (terminated 1563). According to these decisions, the Romish creed embraces the following points:—An admission of apostolical and ecclesiastical traditions; that the Holy Scriptures form only a part of revelation, and are to be interpreted only according to the sense in which they are held by the Church; that there are seven sacraments, necessary for the salvation of mankind, though not for every one—baptism, confirmation, eucharist, penance, extreme unction, clerical orders, and matrimony; that in the mass there is offered a true, proper, and propitiatory sacrifice for the living and the dead; and that in the holy sacrament of the eucharist, there is really, truly, and substantially, the body and the blood, together with the soul and divinity, of Christ (transubstantiation); that there is a place of purgation, or purgatory, into which souls proceed after death; that the saints, reigning together with Christ, are to be honoured and invoked; that they offer prayers to God for us, and that their relics are to be had in veneration; that the images of Christ, of the Virgin Mary, and also of the other saints, ought to be had and retained, and that due honour and veneration are to be given to them; that the power of indulgences was left by Christ to the Church, and that the use of them is most wholesome to the Christian people; that the Holy Catholic Apostolic Church is the mother of all churches, and that out of the Catholic faith none can be saved. To these principal matters of belief are added—the efficacy of prayers for the dead; auricular confession; celibacy of the clergy; the use of Latin in the public ministrations; signing with the cross; the rosary as an implement of devotion, &c.

The Roman Catholic Church is an episcopacy, or government by a hierarchy of bishops. The supreme control rests in the pope and his council at Rome, and thence radiates a system of management, most complete and effective, over all parts of Christendom. The church includes three distinct orders of clergy—bishops, priests, and deacons; all others, such as cardinals (popes expectant), archbishops, deans, vicars, &c., belonging to one or other of these classes. The church claims the mark of true *apostolicity*, that is, an unbroken line of descent from the Apostles and their divine Master. The ordination of priests is the engrafting of them into this apostolic line of succession. Bishops alone ordain or communicate holy orders. In no church is the ritual of public worship so highly adorned, or rendered more imposing, by the dresses of the officiating priests, the waving of censers, crucifixes, pictures, images, and music. Although celebrated in an unknown tongue, it is observable that the public worship excites the greatest appearance of attention and decorum, as well as all the outward demonstrations of piety. The influencing of the devotional feelings is said to be the object aimed at by the various outward insignia; the church (if we understand the argument) holding it to be of equal consequence whether the heart is touched, and feelings of piety and veneration are excited, by the exhibition of a crucifix or the preaching of a sermon. The Roman Catholic Church, though now only a remnant of its former self, is still the most numerous of the various Christian bodies: it includes within its pale, France, Belgium, Poland, Italy, the Mediterranean islands, Spain, Portugal, the greater part of the people of Austria and Ireland; about a half of the Prussians and Swiss, and the

* Review of D'Aubigné's History of the Reformation.—*Albion*, No. 573.

the doctrine of the Trinity, the fall of man, salvation by the expiatory death of Christ, the resurrection, and a state of final rewards and punishments. Differences on other matters may be traced to two distinct causes of controversy—1. Whether the rule of faith and practice is absolutely confined to the Holy Scriptures, or embraces a traditional revelation, sanctioned by councils and cherished by the church? 2. And who has the right to interpret the rule of faith

—the church or individuals? On the exact determination of these points, rests a complex series of divisions, which at present appear to be as far from settlement to the mutual satisfaction of parties, as they were in the sixteenth century; and we may rationally conclude, that, humanly speaking, little or no advance to reconciliation can be effected, till education has dispelled the mists of prejudice, and enabled men to perceive and judge of abstract matters more equably.

inhabitants of various German states; large numbers in the South American states and Mexico; also a part of the population of the United States, and nearly all the Lower Canadians; and a considerable number of the inhabitants of England and Scotland, besides those of inferior countries. Altogether, the number of Roman Catholics is said to amount to 133,000,000.

The *Eastern Church* is divided into four leading communions, and several of a subordinate rank:—1. The Constantinopolitan or Orthodox Greek church, comprising all who acknowledge the supremacy of the Patriarch of Constantinople. 2. The Russian Greek Church, which prevails over Russia, and in virtue of an ordinance of Peter the Great, in 1700, was constituted the national church, having for its head the Russian emperor; it is governed by a council at St Petersburg. 3. The Anti-Byzantine or Monophysite Churches, which have renounced communion both with the Constantinopolitan Church and Church of Rome, and differ from both in doctrine and ritual: these churches include the Syrian, Coptic, Abyssinian, Nestorian, Indo-Syrian, and Armenian Christians. 4. The Greek and other Eastern Churches, including the Maronites in Syria, who are in communion with the Church of Rome. The whole of these Eastern Churches are said to include 62,000,000 of members. Whatever be their peculiar differences, all recognise two sources of doctrine, the Holy Scriptures and Tradition, and are hierarchical episcopates in their form of government. The church service is in Greek. "The rites and ceremonies of the Greek Church are exceedingly numerous, trivial, and burdensome. In all the services, except the communion, prayers and adorations are offered to the Virgin (styled the *Panagia*, all-holy), or to some of the multitudinous saints of the Greek calendar, almost as often as to the Deity. Every day in the year is consecrated to some saint, frequently to more than one; and every day of the week is appropriated in the church service to some peculiar object of adoration."—*Conder*. This church does not resist the circulation of the Scriptures, and its clergy may be married men.

The *Protestant Churches* are either those which split off from the Church of Rome at the Reformation, or others which have since sprung from the reformed bodies. Protestantism owns two fundamental principles—that the Bible contains the sole rule of faith, and that it is the right of every one, without respect of person, to judge of that rule with all the aids which divine grace, reason, and conscience, can inspire. At the same time, it may be noticed, that generally in practice each church possesses certain standards of belief to which it is expected its members will adhere. Rejecting traditional revelation, and the decrees of all councils but those of an early date, Protestants admit only two sacraments, baptism and the Lord's supper. They reject transubstantiation and the sacrifice of the mass; deny the lawfulness of monastic vows, the holiness of celibacy, the merit of good works, the virtue of indulgences, the invocation of saints; reject the worship of images, auricular confession, extreme unction, purgatory, prayers for the dead, and the spiritual authority of the pope. Protestantism exists in three main divisions—Lutherans, Arminians, and Calvinists—each differing from the other in certain points of faith and church government; but there are, besides, innumerable sects which cannot be included in these bodies—as, for example, Quakers, or the Society of Friends, who reject the lawfulness of clerical functionaries, and disapprove of the sacraments and all ordinary forms of public worship—Baptists, a numerous body, with recognised pastors, who possess a very simple form of church government, repudiate infant baptism, and maintain the necessity of the baptism or immersion of adult believers—Moravians, a large and unobtrusive body, who, among other good qualities, display extraordinary ardour in the prosecution of missionary labours—Methodists, a numerous body in England, chiefly distinguished for their devotional fervour, the reformation of manners, and the instruction of the young in religious duties by means of Sunday schools—and Unitarians, an intelligent and respectable body, but differing widely in doctrine from all other classes of Christians; who maintain, as their name imports, the absolute unity of God, in opposition to the doctrine of the Trinity, acknowledge no fixed creed or standard of faith except the Bible, and reject the doctrines of original sin, the vica-

rious sacrifice of Christ, and the eternity of future punishments. Unitarianism has made considerable progress in America during the last half century; and possesses a number of churches in Britain, Ireland, Geneva, Germany, and other parts of Christendom.

The total number of Protestants of all churches and sects is believed to be about 60,000,000.

Protestantism is professed in two chief forms—*Episcopacy*, or the government of the church by bishops, whose spiritual authority is derived from the apostles through the efficacy of ordination, both before and since the Reformation; and *Presbytery*, which rejects a hierarchy of bishops, and admits only the government of the church by a body of ministers all equal in rank. The body called *Independents*, or Congregationalists, only admit of each church being governed by its own members, on a primitive and simple model. At the head of the Protestant Episcopal churches may be placed the Church of England, whose doctrines are contained in the well-known Thirty-Nine Articles and in the Book of Common Prayer. The Church of England has for its basis a denial of the supremacy of the Bishop of Rome, and rejects the doctrine of purgatory, the doctrines concerning indulgences and pardons, the worship or veneration of images and relics, the invocation of saints, the sacraments of confirmation, penance, orders, matrimony, and extreme unction, transubstantiation, and the sacrifice of the mass. It retains confirmation as a religious ceremonial, ordination to the priestly office, the sign of the cross in baptism, burial service, kneeling at the communion, absolution of the sick, the whole hierarchical routine of officials—bishops, priests, deacons, prebends, archdeacons, rectors, vicars, &c., and numerous fasts and festivals. In its calendar affixed to the Book of Common Prayer, there are retained the names of about seventy saints of the middle ages, such as Hilary, Prisca, Valentine, Dunstan, &c. Practically, the church pays no attention to these, or to most of the authorised fasts, festivals, vigils, &c. According to law, the reigning sovereign, whether a king or queen, is head of the church, and has the appointment of its bishops, who hold the dignity of spiritual peers, and are members of the legislature. From its strict connexion with the state, the Church of England labours under the misfortune of possessing no power in itself to amend its formularies, which consequently remain what they were in the reign of Edward VI.; yet this great disadvantage is felt to be comparatively unimportant, on account of the extraordinary beauty and simplicity of the language of the prayers and litanies, as well as the elementary nature of the whole service, which admits of no alteration by officiating ministers. Latterly, a number of its clergy have manifested a strong desire to restore many forgotten ante-Reformation usages in the Church service—a circumstance which has given much offence to those of moderate views. Both in the United States of America and in Scotland, there are Episcopal communions deriving ordination from the Church of England, and having the same forms of worship. The Scotch Episcopal communion, in which the bishops officiate as ministers of congregations, and which is altogether dependent on the contributions of its adherents, is acknowledged to present the purest model of the Episcopacy which prevailed in the early ages of the Church.

Presbyterianism is established in Scotland, Holland, and some of the Swiss Cantons, and exists to a large extent in North America. Presbyterians generally follow the doctrines of John Calvin, rejecting the use of crucifixes, the sign of the cross, altars, liturgies, &c., and recognising no saints' days. Christmas and Easter are recognised by Presbyterians in Holland, but not by those in Scotland. The clergy, being equal in rank, are governed by provincial and general courts, constituted from their own body. Scotland possesses a numerous body of Presbyterian dissenters or seceders from the establishment; and, latterly, these have added to former causes of difference, by declaring their hostility to all connexion between Church and State, and that Christianity, as was the case prior to the era of Constantine, should be entirely independent of civil government, and its ministers supported exclusively by voluntary contributions.

THE PRIVATE DUTIES OF LIFE.

THE temporal duties enjoined on rational beings may be thus classed:—1. Duties which one owes to himself.—2. Duties which arise from domestic relations.—3. Duties which arise in the communities of which each one is peculiarly a member.—4. Duties which arise from the political relations of society.—5. Duties which arise between individuals who are of different nations. We propose, in the mean time, to treat of those duties which a rational being may be said to owe to himself, or, as they are generally termed, PRIVATE DUTIES.

LIFE AS A WHOLE.

Life is a succession of parts—infancy, youth, manhood, maturity, decline, old age, and death. What man becomes, depends in part on his genealogy: as his infancy is, so will be his youth; as his youth is, so will be his manhood; as his manhood is, so will be his maturity; as maturity is, so will be decline; as decline is, so will be old age. If youth be passed in idleness, ignorance, folly, and crime, how can one hold his way in the world, side by side with the intelligent, the worthy, and the virtuous? If manhood has been passed in low pursuits, in rooting in the heart evil propensities, in wasting natural vigour, what awaits one in old age but poverty, pity, and contempt? If infancy be devoted to the reasonable expansion of the physical and intellectual powers—if knowledge of human duty be acquired, and be rightly used, will not manhood be worthy, maturity respectable, decline honoured, and old age venerable? Life, then, must be taken as one event, made up of many successive ones. On these unquestionable truths we found all that is worthy of any notice in the following pages.

PURPOSES OF LIFE.

We believe that human life, rightly understood and rightly used, is a beneficent gift; and that it can be so understood and used. It is irreconcilable to reason, that man was sent into this world only to suffer and to mourn; it is from his own ignorance, folly, or error, that he does so. He is capable of informing himself; the means of doing this are within his power. If he were truly informed, he would not have to weep over his follies and errors. It is not pretended that every one can escape at once from a benighted condition, and break into the region of reason and good sense. But it is most clear, from what is well known to have happened in the world, that each generation may improve upon its preceding one; and that each individual, in every successive period of time, may better know the true path, from perceiving how others have gone before him. There can be no miracle in this. It will, at best, be a slow progress; and the wisdom arrived at in one age, must command the respect of succeeding ones, and receive from them the melioration which they can contribute. We understand nothing of what is called the

perfectibility of human nature; but we understand this, that if human nature can be made to know wherein its greatest good consists, it may be presumed that this good will be sought and obtained. Man was created on this principle, he acts on this principle, although he is seen so frequently to make the most deplorable and distressing mistakes. If it be not admitted that mankind will always strive to obtain whatsoever seems to them good, and strive to avoid whatsoever seems to them evil, their moral teaching is in vain. If this principle be admitted, the sole inquiry is—what is good? and what is evil?

INFANCY.

Every human being comes into the world with physical and intellectual qualities, propensities, and aptitudes, which distinguish him as much from all other beings, as he differs from them in figure and appearance. As society is a consequence of the Creator's will, as the proper divisions of labour are a necessary consequence of society, it is not irrational to suppose that individuals are born with adaptation to labour in some departments, and not in others. In the early stages of life, these qualities are sometimes developed, whether they happen to be understood or not. But almost immediately after gaining some hold on life, all human beings become subject to the incidents which tend to strengthen original qualities, or to obscure or stop their progress, and even to suppress them, and engraft on the original stock those which are entirely different. It would be unjust to make infancy responsible for the evils and errors which arise in this manner; but certainly those who have the guidance of infancy are responsible, and will be held to be so. Children have a right to complain, and society has a right to complain, if duties to children be neglected; and, it is needless to remark, there is another and inevitable accountability of a far more serious character. We shall have occasion to remark on the very sober duties of those, who, according to the order of natural and necessary law, are intrusted with forming and giving effect to natural qualities. This matter properly belongs to another place.

YOUTH.

We come now to a period when accountability begins, in all the relations which were placed in the division of duties. If it be asked at what age this is to be fixed, we answer, that the good sense of judicial law recognises that a child may be a witness in solemn judicial proceedings, when inquiries addressed to him are so answered as to make it certain that he understands the nature and the obligation of an oath. This may be at the age of ten or twelve years. But the perception of right and wrong, and the sense of duty, begin at an earlier age. There certainly are children of the age

of eight years who have a very clear sense of moral propriety; and very many who, between that age and twelve, can discern and reason on right and wrong, and arrive at a very sound judgment. We shall presume that all into whose hands this sheet may fall, will be fully capable of comprehending its purpose, and of judging of its fitness to be useful to them. We must assume, then, that we are speaking to those who are willing to be instructed in serious things, and that they will not reject instruction from any source, however unpretending it may be, if it come to them in a manner which they can reconcile with their own reason, and with their own duty to themselves. Young persons think that they can see for themselves, and that they need not to be told what others have seen. But let us reduce this to common sense. Suppose a person to be under the necessity of going from the place in which he has lived, and which is familiar to him, to a far distant place. Let it be supposed that the road he must travel is crossed by many roads, and that he is frequently to find himself at points where several roads are seen, either one of which, so far as he can discern, may be the right one. Will it be of use to him to have been told, before he departs, which of these many roads to take? Will it help him onward to his destination, when he is bewildered, and unable to decide for himself, to find some one who can assure him of the right course? Life is a journey. Every step we take in it brings us to something new, something unexpected, and perhaps entirely different from that which was looked for. Those who have gone through it before us, have left us their instructions in what manner it is to be undertaken and accomplished. They tell us of their own troubles and difficulties; they warn us how to avoid the like in our own journey. Which is wisest—to listen to them, and weigh the worth of their warning, or to push on heedlessly, and take the consequences?

HEALTH.

We suppose that every child of the ages last spoken of, can form some opinion of the value of health. Most of them have suffered, more or less, by that time. They are now old enough to consider the purposes for which life has been given to them. They then feel that the purpose is to be pleased and gratified; to want and to have; and that restraint is disagreeable. But let them remember that life is a whole; that though all of them will not, yet some of them will, attain to its longest duration, and that it is wholly uncertain to whom that lot will fall. Long life may depend, and often does depend, on what children do, or omit, at an early age. Among the first gratifications which are looked for at this period, is the indulgence of the appetite for food. Here comes in a rigid law of the Creator. It cannot be broken without consequent suffering, nor repeatedly broken without impairing, and perhaps destroying, the material frame which has been described as so fearfully and wonderfully made. To require of that delicate machinery, on which the action of life depends, that which it is not qualified to do, and which it cannot do—to force it to do that which is offensive to it—and to make this requisition habitually—is a sin against natural law. Its punishments are well known. The restless sleep, the heavy head, the many sensations of uneasiness, the positive pain, the disgusting remedies, are the punishments which follow. They are not all. Nature loses its charms, companions their interest, duties become irksome, the mind hates its labour, penalties are incurred, parents or teachers are regarded with displeasure. These are the fruits of momentary gratification of the appetites. On the other hand, there is a law of nature that food shall be grateful. It is required to supply the daily waste—to continue life. If there were not a craving want, we should take food as a mere necessary duty. It is kindly made to be a pleasure, and, like every other pleasure, it is to be used, and not abused. Thus, by ignorant or wilful pursuit of pleasure, we violate a law which brings with its just punishment not only the loss of the like pleasure for a time to

come, but also pain and suffering from indispensable remedies. When children are sick, they are subjects of tenderness and pity; but in most instances they rather deserve to be punished, for they have broken a law wilfully, since they have disregarded their own experience. As to kinds of food, nature is not unreasonably nice about this: that which it complains of is quantity.

CLEANLINESS.

This is not a mere matter of decency. It is one of the positive commands arising from the constituted order of things. Be it remembered, that every thing that lives, vegetable or animal, is wasting while life continues; and that all which is sent forth through the millions of openings by the skin, has run its round, and is lifeless; and that more than half of all the food taken comes forth in this manner. If perspiration, sensible and insensible, be permitted to rest on the skin, and stop the way of that which is coming, nature is offended, and will show that she is so. Such neglect is one of the causes of disease. This fact was probably well known to eastern nations, since it was part of their religious duty to cleanse the skin. These nations were ignorant of the modern comfort of wearing a garment next the skin which can be frequently changed. The absence of this comfort was one of the causes of those dreadful diseases of which we read, and which are now unknown among Christian nations. There are classes of labourers and mechanics, whose health would be preserved, and their lives prolonged, if they knew how much depended on periodical cleansing. It may be said that there is a connexion between cleanliness and moral feeling. Perhaps it may be going too far to say, that those who habitually disregard cleanliness, and prefer to be dirty, have no moral perception; but it may be truly said, that those who are morally sensitive are the more so from respecting this virtue. There is a close affinity between moral depravity and physical degradation. The vicious poor are always shockingly filthy: the depraved rich are visited by worse penalties: they may have clean garments; but what can wash away the impurities which vice has made part of themselves? It is not for one's self only that the virtue of cleanliness commands itself. Every one comes within the observation of others. However uncleanly one may be himself, he is not the less offended at the like neglect in those whom he observes. Now, it is every one's duty to himself to recommend himself to others, so far as he innocently and reasonably can, and to obtain their respect. Clean and costly garments may fall very short of doing this, if it be seen that they are a covering for the neglect of this important law. If there be a lovely object to the human eye, it is a clean, clear-faced, healthy, innocent, neatly-clad, happy child. There are few children who may not, if they will, be neatly dressed, for this does not depend on that of which the dress is made. There are fewer who may not have a clear skin, and healthy look, if they are properly fed, and sleep in pure air. There are none who may not have a clean skin; for we speak to those who are old enough to judge for themselves. And let it be added, for their inducement, that, in obeying the command to be clean, they are performing a moral duty; in neglecting it, they are inflicting an evil on themselves in two ways—first, in diminishing their own comfort; second, in losing the esteem of others.

AIR.

Among the generally unknown causes of loss of health, is the respiration of impure air. The congregation of many persons in one apartment, especially when artificial light, in great quantity, is permitted, is a cause of more maladies than is commonly supposed. Three causes, in such case, combine to destroy the fitness of the air for respiration—the animal heat of the assembly, the lights, and the breathing of the same air again and again. There must be such assemblies. The remedy is proper ventilation. The smoke of lamps has fre-

quently occasioned death. No lamp is properly trimmed if it emit any thing more than a pure bright flame. It is a common practice to keep sleeping apartments shut up. If there be several persons in a small room which has been shut up for several hours, it would be shocking to know how often they must breathe again and again the same air, and how unfit it is to be breathed after it has once visited the lungs. Add to this the impurity of the air, which is continually in contact with the furniture prepared and constantly used for sleeping, in an unaired apartment. It is not mere nicety, or fastidious delicacy, which requires that the pure air should be admitted where the human lungs are in action, but it is a law as old as the creation of man, and cannot be disregarded. A skilful observer might select among many, from the appearance of the countenance, those who have just left an apartment in which they have been respiring for hours a spoiled atmosphere. No doubt that this cause, long continued, so affects the whole mass of blood as to bring on many diseases. If pure air be peculiarly necessary to any class of persons, it is so to children. We believe a more useful suggestion could not be made on the subject of health to the whole community, than to invite them to respect this law of nature—that there cannot be perfect health where the air is impure, and that this applies especially to apartments appropriated to sleep. Visiting friends are often put into sleeping apartments which have not been opened for days and weeks; this is far enough from kind treatment, however innocently it be done.

TIME.

Every person connects himself, in his usual thoughts of himself, with all the lapse of time in which he can remember, and with all the lapse of time through which he expects to live. This he calls his life. He does not live in time that is past, nor in time that is to come. He actually lives only in the present moment. Yet he feels that he lives in the past, and will live in the time to come, because the past, the present, and the future, are so connected, that he cannot separate them. It is, then, a law prescribed to us, from which no one can free himself, that he shall suffer in the passing moment for the wrongs done in time gone by, and for the evils of which he dreads the approach. As this is certainly so, how little does he regard the operation of inflexible law, who provides for himself a load of self-reproach, for any gratification which he can procure by error or by crime!

Let us lay out of the case those errors and crimes which have been alluded to, and consider negligences and follies. Man was meant for action, and his actions were intended to enable him to secure good to himself. Good to himself depends on the performance of his duties to himself. Duty to himself requires that he should improve his faculties, and should avail himself of all the opportunities given to him for that purpose. The hours, then, which are permitted to slide by without any improvement, are lost. In so losing them, he breaks the law of the Creator. Apply this to the vocations in which one is to cultivate his mind in any business, mechanical, scientific, or learned. When one sees himself surpassed by others, and left far in the rear; when he is called on to measure himself against another; and when he sees that comparisons are made between him and others, greatly to his disadvantage—he may feel, and most men do feel, that they are thus depreciated because the precious time which was allotted to improvement has been passed in trifling amusements or in idle pursuits. To some minds, the suffering from such causes is extremely acute. They have no one to blame but themselves. The bitter remembrance which they have of the past, as connected with the present and the future, is the punishment for breaking a positive law. They may console themselves, perhaps, with the firm resolution, that they will repair the wrong done in the past time by diligence in the time to come; but they find that time brings with it its own demands. They are fortunate, indeed, if they can do in one space

that which belongs to it, and that also which belonged to another and in another season of life.

One cannot innocently say his time is his own, and that he may dispose of it as he pleases. His time is his life. It is given to him in trust. Like other trustees, he will be held to an account, in which there is no possibility of concealment, and where nothing will depend on proof. It may be supposed that it will be said to him, 'There was confided to your use a term of time; you knew, or could know, the laws prescribed to you in performing your trust: are you come from that trust to render an account of it, burdened with reproach from your own conscience, and with marks of guilt which you cannot hide? or, are you come without any advancement in the knowledge of your duties, and with no other account than that your days rolled by in childish pursuits or idle amusement, *no wiser* when you were severed from the world than when you left the cradle of infancy? or, are you come with the exalted acquirements which you might have, and with that innocence and purity which you would have, if you had read the laws of the created world, and those which have been revealed and placed before your eyes? Where have you read in these laws, that no duties to yourself, and to your associates, nor to the *Laugiver*, were enjoined upon you? Have you not been told by every breath you drew, by every movement of your frame, by every thought of your immortal mind, by every just pleasure that you have had, by every pang that you have suffered, and by all that you have been made capable of perceiving and learning, that there were laws prescribed to you in your trust, and that an account of your stewardship would be exacted from you by a Judge who cannot be deceived?

SELF-LOVE.

It is an invariable law of nature, that every human being shall do those acts which he thinks will secure good to him, and that he shall avoid those acts which will occasion evil to him. Why, then, should not every one do any and every act in his power by which his own will may be gratified, and avoid doing any and every act which is disagreeable to him? The only answer that can be given to this question is, that man is a free agent, intrusted with the power, and charged with the duty, of ascertaining for himself what is good and what is evil; and that this power and duty extend to those with whom he dwells in society, and also to his Creator.

Children always conform to the natural impulse of self-love, until they learn from the discipline which is applied to them, that they cannot have their own will without subjecting themselves to a suffering, the dread of which controls the natural impulse. They learn, after a time, that the greater good lies in giving up what they will to do, and doing what is required of them, rather than to meet the certain consequences. We think that the whole science of morals will be found in the principles contained in the truth above stated.

Self-love is just as strong throughout life as it is in childhood. It is that quality of our nature to which all excellence may be referred; but it is also that to which all unworthiness may be referred. As the dread of punishment, or an unwillingness to displease those whose kindness a child desires, will restrain him, or put him into action; so, in more advanced life, the dread of suffering a certain or probable evil, and the certainty of losing the good will of others, will restrain or impel to act. With those whose minds have been properly disciplined, and who have learned to comprehend their relation to the Creator, there is a far higher motive, which is founded in a submission to the Creator's laws. As one goes on in life, he may or may not acquire more and more clear and just perceptions of what will be the greatest good to himself, and how he can obtain it. It is a self-evident proposition, that if a person could certainly know what it would be best for him to do, or not to do, in relation to all things and persons, and under all circumstances, and if he should conform to this

knowledge, he would best obey the impulse of self-love, and most exactly conform to the laws prescribed for his good.

It cannot be too often impressed upon the youthful mind, that *life is to be taken as a whole*: for if this extended view be not taken, it must frequently happen that it will seem right in certain circumstances, and when the view is limited to these circumstances, that certain acts may be done or avoided as the greatest good. Yet, if the consequences could be foreseen, they would disclose that this seeming good would turn out to be a positive evil. It often seems good to the young to avoid the performance of labours which are assigned to them, and to spend in amusement the time which should be devoted to fit them for duties which will be incident to their future condition. This misapprehension of good is to be lamented; but with some this is not all. Their own self-love prompts them to engage in a course of folly, so that not only do they fail to obtain that which is real good, but they find, under the mask of pleasure, that which proves to them to be the most grievous suffering.

The same truth runs, in an endless variety of forms, into manhood, and through all the stages of life. We are impelled by self-love not only to provide for the craving wants of our nature, but to seek pleasure, riches, power, distinction, and luxuries. These propensities are given for wise and beneficent purposes. It is the misapplication of them, as seen in the world, which constitutes human misery. He is called brave and honourable who defends himself, even at the risk of life, against those who would do to him that injustice and wrong which would make the gift of life of no value. But the brave, who invade the rights of others, and subject them, by violence, to losses and to sufferings, without cause, misapply this principle of action. To get riches by honest industry, or the reasonable exercise of one's talents, is a commendable use of self-love. To get riches by unfair and dishonest means, to hoard them up, and to brood over them in secret, is a pitiful misuse of this commendable impulse. To have power over one's fellow-men, and to use it faithfully, and for their benefit, is a relation which one may honestly and commendably desire, as a reasonable exercise of self-love. To seek such power by deceitful representations, and to obtain it by violence and fraud, and to use it for purposes of supposed self-benefit, and to the injury and oppression of others, is another form of self-love. But there are few, if any cases, in the history of mankind, in which self-love has appeared in the latter form, without eventually overwhelming the agent with disappointment and sorrow. It is true that for a time such an one may seem to flourish in his schemes, and command the applauses of those who look up to him in his apparently fortunate elevation; but, in the very nature of things, if his heart could be sounded, there is no one whom he looks down upon, who is not more at ease than himself. His day of humiliation may be at hand, in the course of events which he cannot control; and if not, he learns, when it is too late to correct his error, that he has misapplied the impulse of self-love. This misapplication is to be seen in many cases of daily occurrence, and in things of little, as well as in those of comparatively great, importance. The principle is every where the same.

We shall be answered, perhaps, that all this is incident to human nature. There is no help, it is said, for these evils. Every boy who has learned Latin repeats the maxim, *Humanum est errare* (It is human to err). A more mischievous maxim was never invented. If men understood, as most certainly they may do, that they need not err, and that it is best for them they should not, they would rather adopt as a maxim that none but the wilfully ignorant, and the wilfully foolish, err. Such a state of things is yet afar off. It may seem to be foolish, indeed, to assert that any society should ever come to be so well informed as to make a proper use of self-love. Let us not despair. We may improve very slowly; yet, if every one does even the

little that he can, in showing, by precept and example, what things a rational and accountable being should desire, and what he should avoid and reject, certainly the time may come when self-love will never be so misapplied as to be necessarily followed by penitence and sorrow.

Will it be denied that there is a certain best course of action for every human being, in every possible condition in which he may find himself? Or, that no small proportion of human suffering arises from not having discerned that it was best, in past circumstances, to have acted differently, or not to have acted at all? Or, that whether one did or did not act, in the supposed case, that his motive was to secure to himself the greatest good of which that case was supposed to allow? If these things cannot be denied, then the great end of life is so to regulate self-love as that it may secure the greatest good. Let us suppose that every person in society knew what it would be best for him to do or not to do, so that his physical, intellectual, and moral condition, should be as good as he could make it. His self-love would never be directed to any end which would impair his bodily powers, or keep his mind in ignorance, or misinformed, or make him a subject of reproach or contempt in his own view, or in that of others. This, it will be said, is an impossible state of things. So it was said that it would be impossible to root out the use of *ardent spirits*. This great change is not wholly accomplished; but does any one doubt that great advance has been made towards its entire abolition? Let us go on, then, in the work of improvement. Let every one try to show the proper uses of self-love. The day may come when every one will admit that all the sufferings which may visit the human family are of their own making, those only excepted which arise from the general laws of the Creator. As to those, they may be greatly mitigated by intelligent moral agency. When these come, they can and will be endured with piety and resignation, if the sufferer can console himself with the certainty that he has done no wrong thing, nor neglected any proper one, to which the cause of his sufferings may be referred.

LABOUR.

It is commonly considered that labour is the *curse* declared to mankind, as a consequence of the transgression of the *first man*. It is foreign to our purpose to enter into any discussion as to the true meaning of this historical or allegorical account; the Christian revelation may not be dependent on a literal understanding of it. However this may be regarded under the influence of further reasonable research, we must take man as he is; and so considering him, labour is not an *evil*, but a *pleasure*. Is it a curse to man, as he now is, to be enabled by labour to comprehend the existence of the Deity, and the beauty and utility of his works? to adorn the earth and bring its productive power into action? to apply the material substances of the earth to reasonable use, convenience, and ornament? to expand and improve the human mind? to cultivate and strengthen the moral power? Certainly these are the effects of labour; and labour so applied constitutes man's highest happiness.

There are two kinds of labour:—1. Mere bodily labour; 2. Labour of the mind. These two are sometimes necessarily combined. The mind and the body demand some sort of employment. No one whose mind is free from natural defect can prevent its action. It will think of something, good or evil, profitable or foolish. Every one who attends to the operations of his own mind, must be convinced that this is so. The body and limbs cannot be kept in any one position for any considerable space of time, unless they have been in action and demand repose. If it were painful to us to direct the action of the mind to useful labour, and if it were distressing or inconvenient to us to exercise our muscles for purposes which we believe to be proper, then it might be that labour is a curse; but many, nay all, who require of the mind to perform its duties to any

useful purpose, and especially those who have disciplined the mind to an accustomed service, find that the absence of employment is an affliction. We cannot see how this should be otherwise, if we rightly comprehend man's relation to the universe, of which he constitutes a necessary part.

As to bodily action, it is seen that children in their sports go through a series of exertions, often exceedingly violent too, from mere pleasure. Men frequently exercise the body much more severely in matters of amusement than they have any occasion to do in necessary labour. This action seems to be a dictate of nature. In many cases of indisposition, bodily motion is the prescribed remedy, and is commonly a successful one. There are sound reasons why this should be so. There is an universal action of the material system to which man belongs, and a continual waste and demand for supply. Excepting only in the involuntary movements in man's structure, which are not confided to his care, he is required to aid nature in her operations. If he would put himself in the best condition to receive and derive pleasure from his daily food, he must keep himself in action. Those who have the least pleasure in using what was given to be used as the means of pleasure to the senses, are those who keep the body inactive. This is true of those who labour with the mind only; more strikingly true of those whom affluence excuses from labour of body and mind. They seek happiness in indolence and in luxury. They find it not, because they violate a law of nature. No product of the vineyard, the field, or the sea, however aided by inventive art, will furnish a welcome repast to one who sits in listless idleness, on a downy cushion, from breakfast time till dinner. The day-labourer who sits down to his coarse meal, has a pleasure to which the luxurious idler is a stranger. The one receives a rational benefit from the kind and just bounty of nature; the other seeks it where nature has decreed that it shall not be found.

The labour of muscular action is not only in itself a pleasure, but it is the means prescribed to us for the acquirement of subsistence; for the gradual improvement of society; for applying natural and artificial products to our comforts, to our convenience, and to reasonable luxuries. Nor only so: this is the groundwork of all the beautiful and imitative arts; of the discovery and application of the chemical power of matter; of the wonderful contrivances by which man securely moves on the face of the ocean; by which he cultivates his acquaintance with the stars, and raises his thoughts to the Author of all being. Let us not, then, regard labour as a curse, but a blessing, and rank it among the many causes for thankfulness. It is obvious that muscular action would have been given to us in vain, if it were not directed by intelligence. There must, then, be labour of the mind. This is nowhere said to be a curse. If there be any thing for which we should be specially thankful, certainly it is that we are blessed with the power of mental exertion. This labour is in itself a source of happiness; and in its fruits has made, out of savage man, a rational and improving social being. The most restless and comfortless of all creatures is he who has no occupation for his mind. If one would invent the most miserable condition for a human being, other than mere physical suffering of the most excruciating kind that can be without extinguishing life, it would be to deprive him of all employment of body and of mind.

Can there be a doubt that, in man's present condition, the ability to labour is his exalted privilege? And is he not accountable for this privilege? Is not reason given to direct him in the use of it? It is well known to those who have compared the condition of mankind in different ages, how much the labour of body and mind have been able to accomplish. Even within the last half century, the most surprising changes for the better have taken place, from the right use of this productive power. On this depends the condition of the human family. From the joint labours of all who wish well to their fellow-men, there will be obtained, eventu-

ally, the knowledge of the best manner of using the products of the earth, the best mode of ruling men in their social relations, the just homage due to the Creator, and the true purpose for which human life has been given.

To some descriptions of persons, labour is irksome. They are obliged, in their vocations, to use certain muscles, and those only. They repeat the same act throughout the day. Their labour becomes tedious, because it requires little or no action of the mind. To this numerous class we venture to offer a relief which is within the easy reach of many of them. It is well known that the nature of habit is such, that the hands will do what they have been accustomed to do, without any obvious attention, and the mind is left to do what it will. The mind might be employed, while the hands are busy, in pursuing some connected train of thought. Muscular action, so far from being an interruption to the action of the mind, may be made to assist it. Persons who think intently are often seen to have some habitual movement; and we have heard several persons acknowledge that their best ideas had come to them when they were engaged in some simple occasional duty, such as the folding of paper, or the cutting of the leaves of a book. The stir of body seems to produce a corresponding stir of mind. The relief which we suggest is, that sedentary labourers should provide themselves with subjects for reflection, and exact of their minds to attend to these subjects. By such simple means, the memory may be strengthened, the stock of knowledge may be greatly increased, and the mind surprisingly invigorated. One might begin this exercise by attempting to remember, with the utmost precision, every act done during the preceding day, and so go back from day to day. Better still would it be, if the purpose were to see wherein one had not done as well as he might, and as he may wish he had done. This exercise may be applied, also, to the contemplation of subjects suggested by reading; and this contemplation will raise questions which will lead to the examination of books. There may be hundreds of poets, philosophers, and moralists, at the work-benches in this country, who have no thought, of themselves, that they are such. It is in the power of any person who can read and understand the English language, to strengthen his memory, give himself an interesting employment, and furnish himself with a rich fund of the truest philosophy, in this manner. He may commit to memory six lines, each successive day, of Pope's Essay on Man, and on each day repeat all he had learned on preceding days. On the 218th day he would be able to repeat the whole essay. This might be done without losing one moment of time, and without making the slightest error in one's work. When accomplished, it would be an intellectual treasure for which any man might be thankful, and of which he might be justly proud. The first efforts may be discouraging, but perseverance will ensure success. Every one who is accustomed to thinking can attest that most new subjects are at first confused and undefined; but they gradually disclose themselves, and fall into shape and order, just as material substances, used on the work-bench and the anvil, take that form, smoothness, and polish, by successive operations, which the workman requires.

HABIT.

This quality of our nature has engaged the attention of many philosophic minds. It has been considered an *ultimate fact*, as it is called; that is, one of those qualities, which, like respiration, digestion, and many others, are found to exist; and beyond which fact no investigation can be made. Its laws, rather than its nature, have been the subject of remark. It may be, that habit is to be referred to the law of action, which appears to pervade all material and intellectual being. Life is divided into parts; in one we are awake, and active; in the other, wrapped in sleep, and quiet. Each successive day is a sort of new existence, in which we are to repeat many of the acts of the preceding day. We

repeat these acts, because nature demands the repetition of them. Also, almost every one is engaged in some vocation, on which he relies to supply his wants and gratify his wishes; and most persons have in view certain pleasures, which are innocent, or otherwise. It seems to us that habit arises from this demand for action, and from the manner in which this demand is supplied. Action relates to ourselves, to other persons, and to things around us which minister to our wants; supplying its demands associates us with these persons and things. The want, whatever it may be, arises, and forthwith all things connected with satisfying it force themselves into notice, and these become a part of our very existence. It is a well-known fact that the appetite for food will associate itself with a particular hour of the day, and with persons, places, and objects of gratification; so that one becomes hungry rather according to the hour than the natural want.

It may perhaps be an ultimate fact, beyond which we cannot go, that those acts are most easily and well done which are oftenest done. One who uses a flail, an axe, a scythe, a sword, or a pen, can use either the better the oftener it is used, until he arrives at a point of excellence at which his power of improvement stops. This may perhaps be accounted for by supposing that the first effort which the mind makes to direct muscular action, is the most difficult one. After repeated efforts, the mind seems to understand better and better how to direct, and the muscles how to obey, till at length a very slight effort of the mind seems to be all that is required, and even an effort so inconsiderable and rapid as not to be the subject of notice. On this truth seems to depend the astonishing facility of action to which (among many other instances) jugglers and musicians attain. This is called *habit*, which word is derived from a Latin word which signifies custom or use. There are customs or habits of the mind as well as of the muscles. Persons who accustom themselves to extemporaneous speaking, acquire a surprising ease and readiness in the complicated action of conceiving, uttering, and expressing, by sounds, by looks, and gestures, whatsoever they would impress upon an audience. The mind has its own habits also, in the quiet of contemplation, and in exercising its various powers. It has its own associations, too, with external objects, of which many curious instances are stated in philosophical works.

The moral deduction which we make from these general principles is this, that there is a continual craving to do some act, to obtain some object; or a continually recurring necessity to do some act, to prevent an evil or inconvenience. The frequency of this call upon us to do something, whether it be for eventual good or evil, leads to the practice, custom, or habit of doing; and in some cases the impulse to act becomes so powerful, that reason, self-respect, the laws of society, and even those of the Lawgiver of the universe (if these are heeded), present no sufficient barrier to the impulse. It is to this all-important truth in the nature of man, that we earnestly invite the attention of the young. The capacity to create habits is the consequence of the power given to us to promote our own welfare, individually, socially, and as accountable beings. This capacity was designed to fasten us down to that course of action which will accomplish these ends of our existence. Like every thing else with which we are intrusted, it may be rightly and profitably used, or may be misused, and perverted to our certain ruin. Habit is the kindest friend or the cruellest foe to human welfare. When it assumes the latter character, it approaches us in the most deceitful and seductive forms. It comes wearing attractive smiles—it delights—it fascinates—it substitutes its own irresistible will for our own—it triumphantly points to the gulf to which it bears us. The fly caught in the spider's web is a faint illustration of the power of habit. He knows, from the first moment, his destiny. The gambler, the drunkard, and the felon, when and how do they learn that they have been caught in the web of habit!

INTEMPERANCE.

This word has attained a meaning more limited than its proper one. It is applied commonly to persons who take habitually ardent spirits; but it is equally applicable to all transgressions of the law of moderation. All acts which may be lawfully done for one's own good, when carried to excess, are acts of intemperance; and all such acts are sooner or later followed by some sort of suffering, according to their nature and degree. Excessive labour of body or mind is as much an act of intemperance as to make one's self dull and stupid by taking food, or irrational and giddy by taking spirits. But there is a wide difference in the degree of immorality in the kinds of excess. An intemperance in study, which brings untimely death in some instances, is not condemned as an immoral transgression (though it certainly is such), for the motive which leads to this intemperance is an honourable one. The loss of health and character, from abusing the privilege of taking nourishment, is universally condemned, because the motive, and the acts done in obedience to its impulse, are irrational and disgraceful.

There are two kinds of intemperance against which the young should be warned. The one is drinking, not for nourishment, but for pleasure; the other is, using tobacco. It has been already demonstrated that nature requires a certain quantity of proper food to maintain a healthy and happy condition of body and mind; also, that excess of any kind will be followed by suffering. This is just as certain as that a full vessel must throw off just as much as is added to its contents. It is very natural that young persons should assemble for the sake of society; being assembled, they must have some employment for the muscles of the body and the craving of the mind. We have shown that such propensities spring from natural constitution, and that they must be satisfied. There must be a community of purpose in the meeting. That may be found in any muscular action in which all can join, and which has some definite object, as athletic games; or it may be found in some intellectual employment which is common to all present. Unhappily, the most frequent bond in such meetings is to *drink*, for in this all can join. Connected by this common attraction, the mind is called into action; but for what purposes? Those who frequent places of public entertainment can answer this question. Some who are sent to public seminaries can also answer it; and some can answer it who know that they are maintained *there* by pinching economy *at home*. Some others could answer it, who never had a serious thought why such places were established, nor for what uses they were intended.

We refer again to the demonstration heretofore made, that the law of nature, which cannot be broken with impunity, inexorably admits so much, and no more. Let us, then, look in upon a gay company of young persons, around a table, and half concealed by tobacco smoke. What sort of air are they breathing? what sort of substances are they casting into their physical system, already bursting with excess? what sort of thoughts have they in their minds? and what sort of words are flowing from their lips? We *could*, but will not, answer these questions for them. Let us pass by this revel, and go to the next morning. We might then propound some other questions. Are not their heads heavy, hot, and throbbing? Are not their eyes thick and burning? Are not their tongues white and parched? Do not the nerves tremble? Is not the mind muddy and confused? In what condition are they to perform duties to themselves, to those they serve, to instructors, to affectionate parents? *Is not this dear-bought pleasure?* How long can nature bear to be pleased in this manner? This matter does not stop here. The same scene is repeated again and again. *Soon habit asserts its awful dominion*; and then the scene must be repeated. The craving cannot be resisted. From social drinking, the step is an easy one to solitary drinking. *There is no resting-place for habit*;

every thing in this system of being must keep on, or end.

It is believed that the sort of criminal excesses to which we allude, are not from the promptings of nature. We venture to assert that they are entirely artificial in the beginning. It seems irrational that any one should like to take more of any thing than nature requires; and more so, that one should naturally desire to take burning liquors to the degree of intoxication, or perhaps to take them at all. It is believed there is no such natural propensity; but that such liquors, when first taken, afford less pleasure than pure water. The taste for these articles is created by association, by imitation, by fellowship; and, above all, because there is a kind of tradition that it is *manly* to drink. Songs in praise of the juice of the grape, and of meaner liquors, have some effect in the delusion of drinking. There is a fascination in combined poetry and melody. Such combinations are well known to have the most powerful influence in national associations. They inspire a feeling which bears men on to victory or death. The songs of Bacchus do the same. They conquer the strength of those who sing, and of those who listen to them, and sometimes lay their admirers not in the bed of honour, but of contempt.

If one could get the ear of such a misguided youth, he would not do much by reasoning with him. He might do something by getting him to reason for himself. It would be necessary to bring to his view some facts from which he could reason. He must be made to know what a wonderful contrivance the digestive power is, and by *whom* it was contrived. That its purpose is to take the inanimate substances which nature provides for it, and convert them into living sensitive being, and, possibly, into thinking power and immortal spirit. He must be reminded how easily every human contrivance may be deranged, and the more so, and irreparably, in proportion to the minuteness and delicacy of construction. But as one might fail to make a thoughtless boy comprehend the nature of the principle of life which resides in his own bosom, because he cannot see it, some illustration must be made. Unhappily, there is none which can be effective to this end. The nearest that occurs is this. Let us suppose, then, one knows the use and the value of the human eye in its physical, intellectual, and moral relations; that he knows he must take care of it, and frequently bathe it in cold water, as well to cleanse it as to refresh and brace it, so that it may still be an eye to him, when decline and old age shall come. Let us further suppose, that, instead of so using and so preserving this delicate organ, he should, when he first rises in the morning, let fall into it a drop of burning spirit, and at eleven o'clock another, and so on, at the proper hours, until he sleeps again—how long would the power of vision remain to him, and how soon will this organ of delight become a source of insufferable pain? It must be much the same with the digestive organs as to the abuse of them.

If one could, in some such way, bring home to the perception of an erring youth the grievous wrong which he is inflicting on himself, he might be prepared to reason on his own case, and might be asked some such questions as these. Is it of any consequence to you to be free from suffering and sorrow? As you must inevitably keep company with yourself as long as you live, is it of consequence to you to make of yourself a pleasant and agreeable companion, and not one who will be continually complaining and upbraiding? Is health of any value to you? Can you use your limbs, and the faculties of your mind, as you would like to do, without it? Can you have health, if your habit is to throw into that delicate part of your system whereon the action of life depends, substances which excite it to an unnatural exertion, or deprive it of all power of exertion? Does not every part of your system sympathise with the injustice which you do to your digestive organs? Will not your brain, and consequently your mind, suffer by this violence? Do you expect to attain middle age, and

old age? Will not the seeds you are now sowing come up in that space of time? Will they come up in the form of enfeebled muscles, chronic aches, self-reproaching thoughts, the loss of the capacity to enjoy the bounties and beauties of creation? Will they grow up to overshadow your moral sense, and shut out the delights of intellectual power? Was life given to you for the few years in which you can sing, drink, and "enjoy yourself," or that you may enjoy life in every stage of it, as a rational being, and by rendering your homage to nature in obeying her laws, and your gratitude to Him who ordained these laws for your happiness? Do you not look forward yourself to be at some time a parent? Have your own parents ever so conducted themselves towards you, that you have a right to punish and afflict them? Are you willing that your parents should see you and know you as you know yourself? If you should be a parent, are you willing that your children should be told with whom, and in what manner, you "enjoy yourself?" Would you tell them how you spent your youthful days and nights, and recommend to them to take yourself as an example?

TRUTH AND FALSEHOOD.

These two subjects relate to two parties: 1. That one who speaks truth or falsehood; 2. That one to whom it is spoken. We propose to consider this matter only in relation to the first party, and as to him in two views. 1. Whether there be any, and what law, which requires that the truth should be spoken; and, 2. What good or evil one may do to himself by lying.

1. One reason why truth should be spoken is, that the knowledge which any one person can have from the use of his own senses, in many things which it most materially concerns him to know, is very limited. He must therefore often depend for his knowledge on what others say to him; and when the thing spoken of is exclusively known to the party speaking, the other must rely entirely on what he says. If, therefore, it be considered how great a part of the most serious concerns in life proceed on declarations made by one person to another, we may readily conceive, that, if these could not be relied on, the affairs of mankind would be greatly embarrassed, and confidence in each other would be destroyed. As this matter of speaking the truth is one which concerns all persons, so all persons agree in holding liars in contempt. Even the very lowest persons consider themselves to be disgraced when charged with the guilt of lying. They can endure charges which would subject them to public punishment, with more composure than they can endure this. A lie is always understood to be resorted to to secure some advantage or prevent some evil to the person who resorts to it; or to occasion some disadvantage or injury to the person to whom, or of whom, the lie is told; sometimes both these purposes concur. The object in view is always an immoral one, and the means used are always regarded as disgraceful. It is at once obvious that wilful falsehood is forbidden by natural law, which is intended to regulate our social relations, and is expressly forbidden by divine law, which condemns all acts of fraud and deceit, and commands us to do to others as we would have them to do to us.

2. It is a rare occurrence that any one who descends to falsehood succeeds in the object which he may have in view. He is commonly detected, and, if not, is suspected, which may operate quite as much to his disadvantage. If he should escape detection and suspicion, he lives in constant fear of both. He has a very troublesome secret to keep. If he should be able to do this, still he cannot hide it from himself that he is a liar; and such a person, by natural justice, is compelled to pass that sentence upon himself, which he knows that others would pass upon him if they were as well informed as he is. A liar is therefore obliged to feel like a guilty person, and a habitual liar very soon comes to look like one. If there be no higher motive than one's own interest and welfare in speaking the truth and avoiding

falschood, this is a very sufficient one. If a man is known to be a person unworthy of confidence when he speaks, he has not the benefit of being credited even when he speaks the truth; he voluntarily deprives himself of the advantages of social life; his assertions secure to him no credit; his promises are contemned; he makes himself to be alone in the very bosom of society, for every one shuns him. In the administration of justice in courts, a person is not regarded as a witness, whose common reputation is that he is not believed when he speaks. The objection to him is not that he might not tell the truth in the matter which is on trial, but that such a person ought not to be received as a witness, because he cannot be credited in any thing that he says. When such a person has been called and examined as a witness, it is usual to examine other witnesses to prove his character; and if it be proved that he is unworthy of credit, what he has sworn to is disregarded, though he may have declared the truth. This is the common fate of all such unfortunate persons in society, as well as in courts. Independently of the criminality, lying is very poor policy. If the object be to obtain a supposed good, it rarely is obtained by such means; and if it be, the price so paid must always be greater than the good is worth. If the object be to conceal a wrong done, it is rarely successful; and if not, it leaves the offender without excuse for his error, and adds another wrong. If the object be to charge an innocent person with a wrongful act, or to deprive one of his good name, or of some lawful possession, or subject him to some evil which he ought not to endure, the offence is of that cast which the law of the land holds to be *malicious*, and it deals with such offence accordingly. In short, it is very difficult to violate any law of natural justice or divine prohibition without encountering an adequate punishment; and it may be assumed that the punishment which follows lying is as certain and just as in any instance of criminality. If every tenant of every prison, and if every person who is in the custody of a goading conscience, were asked this question, *What was your first step from innocence and purity?* he would probably answer, *Telling a lie!*

SINCERITY AND INSINCERITY.

These are other names for truth and falsehood. They are not commonly applied to the most serious concerns of human life, but to what are called the "imperfect obligations." Such obligations, it is well known, are not enforced by the law of the land, but are binding as duties arising as well from natural law (reasonably expounded) as from divine law. Sincerity is a duty to one's self, because it is demanded by self-respect. As every one has an individual separate physical being, so every one has a *separate circle* within which he exists, and into which no one has a right to intrude. His thoughts, motives, opinions, and policy, are his own. What he will or will not do (so that no wrong be done to others, and no act of duty be withheld from them) is for him to decide upon. Within this circle, he makes up his judgments on all persons and things. In his outward deportment, he must frequently act in a manner not consistent with these judgments. As an example: one has made up, from repeated observations of a certain individual, a very clear but very unfavourable judgment of his qualities; but there is no occasion to disclose what the judgment is. The observer is obliged, or finds it convenient, to meet this individual, and to deal with him, and perhaps to interchange courtesies with him. It is undoubtedly proper to manifest the respect, in such case, which the decencies of life require, and to show the common proofs of good will. There is no insincerity in this. Though no one can possibly avoid forming judgments of others, nor avoid liking or disliking them, even including very near friends and relatives, yet there may be a positive violation of duty in publishing these judgments or in disclosing these feelings. The Divine law, "judge not that ye be not judged," does not, it is believed, interdict these judgments, because they cannot but be made;

but it forbids the wanton, unnecessary, and injurious publication or manifestation of them. Those who are keen observers of their fellow-men, see in their faces, in their manners, in their modes of speaking, in their tones of voice, in the sentiments which they express, &c., causes for respect, esteem, confidence, and approbation; or they may see causes for disrespect, suspicion, strong disapprobation, and disgust. But all these things belong to the *individual circle*. It is not insincere to keep them there. On the contrary, society would be intolerable if they were not kept there; it is very hazardous to the observer to let them out unnecessarily. He may be mistaken both as to the favourable and unfavourable judgments which he forms. Further observation, new circumstances, unexpected changes, may essentially correct his judgment; and, therefore, a prudent man will keep them to himself: they are his own peculiar property, and were obtained for his own use. Insincerity is often demonstrated by paying false and silly compliments, which assume the form of *flattery*—a word which is derived from the Latin, and signifies wind, breath, puff. This is a kind of aliment which perverted self-love finds to be exceedingly pleasant. Although it is in truth precisely what its origin indicates, there is hardly a man, woman, or child, who is not disposed to partake of it, if it be artfully disguised. But, on the other hand, all sensible persons, of whatever age or sex, who see what it is, and why offered, feel for the flatterer the contempt which he deserves. This insincerity is, and ought to be, deemed a high offence. It implies art and deceit in the flatterer, and sufficient weakness in the flattered, to be subdued to the purpose in view. The flatterer's purpose may be to secure to himself no more than a better esteem than he can have any pretence to, and it may be, through that, to secure to himself something which may be very costly to his victim.

CIVILITY.

The well-being of society would be greatly promoted if the nature and use of this Christian virtue were more generally known. We take this to be, in personal intercourse, the observance of the command, *Do to others as you would that others should do to you*. The most rapid glance at any community shows this—that some of its members are brought into contact, in matters of business, necessarily; others meet, incidentally, who have no particular connexion; others meet for social purposes, in various forms; and that there is a large proportion who know of each other very little, beyond the fact that they are of the same country, and perhaps not even that. There must be a *best rule* of deportment for all these classes; and no one will deny, that if this rule were defined, and faithfully applied, there would be much more of everyday comfort and complacency in the world than there is well known to be. If we rightly understand the meaning of civility, it is the manifestation of kind feelings, and of a desire to do all things which are to be done under the influence of such feelings, in a becoming and agreeable manner.

If every person understood the true foundation of society, the common origin of all its members, their natural and necessary sympathies, their community of interests, their necessary action upon and with each other, it might be supposed that all who are reasonable would be civil. They would be so, because they would promote their own good, because they would be doing what it is proper to do to promote the good of others; and because they would know, that in so doing they would conform to the design of their creation. We do not include under the term *civility* the great duties of justice, acts of munificence, important personal services. These arise out of some special relation which an individual bears to one or more other individuals. It seems to be limited to the manner in which the common or accidental intercourse of the members of society in general should be carried on. This matter may be better understood by some examples. Thus, if one comes into the presence of another as a beggar, servant,

labourer, mechanic, trader, merchant, farmer, lawyer, physician, clergyman, or public officer, or if it be a female, or child of either sex, there may be very various modes of receiving these different persons—yet, certainly, by every one of the laws which we are endeavouring to illustrate, these several persons are entitled to civility. Even the beggar—perhaps one should rather say, the beggar in particular—if not deformed by voluntary transgression, should be received with civility; that is, gentleness, kindness, decorum, are to be observed relatively to each one. Why? because no man can afford to be deemed insensible to the cause of reasonable humanity; nor a stranger to the decencies of life; nor ignorant of what is due from him, nor to him, in any of his proper relations.

There is one other consideration which operates on all men who have had much experience in the world. Men and things change, and take new and unexpected relations. Persons who have been long, and even intimately connected, suddenly or gradually sever; persons who have known little of each other, and that little uninteresting or unfavourable, are brought in contact by some unexpected turn of affairs. Sometimes one needs favours, or at least good will, from those he never thought to be of the least importance to him. In such, and in a multitude of other circumstances, one may find the advantages of having been acquainted with the virtue of civility, which implies that one has given no unnecessary offence. There are other cases in which one is called on by duty to do things disagreeable to himself, and exceedingly so to others. But there is no good sense in performing such duty morosely, and with inhumanity.

POLITENESS—GOOD MANNERS.

A refined species of civility is sometimes expressed by the term *politeness*, which is an exterior indication of good breeding or good manners, and may be defined as that mode of behaviour, which not only gives no offence, but which affords agreeable sensations to our fellow-creatures. In our intercourse with the world, this species of civility is imperative. We possess no right to give offence, by language or actions, to others; and we are bound to conduct ourselves agreeable to the reasonable and set rules of society. Some severe writers on morals have confounded *politeness* with *insincerity*. They seem to imagine that the act of speaking gracefully to another, is necessarily mere grimace, or an empty flourish signifying nothing. In many instances, with insincere people, this may be the case, but it is not so with those of well-regulated minds. It is always better to speak politely, that is, with extreme propriety and delicacy, than coarsely, sulkily, or impertinently. We say, cultivate politeness of manner by all means, for it is *refined civility*, and will spare both ourselves and others much unnecessary pain.

Civilised society has in the course of time instituted certain rules in the code of politeness, which, though of little actual value, it is every one's duty to learn, because, by knowing and acting upon them, we can make life glide on much more smoothly and pleasantly than if we remained in ignorance of them. These rules are sometimes called the rules of *etiquette*. We shall here mention a few of the more important of these social regulations:—

1. *Honour to the female sex.*—Women are physically weaker than men. They are unable to defend themselves from insult or injury, and it would be considered indelicate for them to do so, even if they possessed the power. For these and other reasons, it is only simple politeness and a sign of good sense to render any little service to women—to assist them when they appear in any difficulty, to speak respectfully of them and to them, and to give them honour whenever it can be reasonably required. It will be observed, therefore, in what is called good society, that women are treated with exceeding delicacy and deference: they are offered the best seat, or the only seat if there be no other; allowed to walk next the wall, or at the farthest point

from danger, in the street; never rudely jostled against in a crowded thoroughfare; and are always parted from with a respectful bow. All this is considered essential in good manners, and attention to it will not in the smallest degree degrade any man in the opinion of the world. At the same time, as respects the women who receive these attentions, it is expected that they will not “give themselves foolish airs,” or presume on the forbearance and kindness of the stronger sex. In fact, no female will do so who is acquainted with good manners, or wishes to avoid being despised.

2. *General courtesy and respect.*—It is incumbent on every one to be courteous or respectful in his intercourse with neighbours, acquaintances, or with the public generally. To inferiors, speak kindly and considerately, so as to relieve them from any feeling of being beneath you in circumstances; to equals be plain and unaffected in manner; and to superiors, show becoming respect, without, however, descending to subservience or meanness. In short, act a manly, courteous, and inoffensive part in all the situations in life in which you may be placed. Society, for good and sufficient reasons, which it is needless here to explain, has ordained certain modes of address, and certain exterior signs of respectfulness, which it behoves us to support and personally attend to. In eastern countries, as of old, it is the custom to uncover the feet and to sit down, in token of respect, on going into the presence of kings, or on entering any religious edifice or private dwelling. In our country, the custom is entirely the reverse. It is an established mark of respect to uncover the head and to stand, in the situations which we have mentioned, and to this point of etiquette we are bound to adhere. We must not, from any crotchet of our own, violate the rules or customs which society sanctions and enjoins, as long as these rules and customs are not opposed to reason and sound morals, and only refer to such trivial arrangements as taking off our hat, making a bow, shaking hands, or other matters equally unworthy of deliberate consideration. None but persons of a silly, eccentric turn of mind, think of disputing about these trifles. On the same principle, give every one the title, which, by law or courtesy, he usually receives.

3. *Personal behaviour.*—A well-bred man is always known by the perfect ease and tranquillity of his manner. These are points to be carefully cultivated. Acquire, if possible, an easy confidence in speaking, so as never to appear abashed or confused, taking care, however, not to fall into the opposite error of forwardness or presumption. Persons moving in the highest circles of society never allow themselves to appear disturbed or vexed, whatever occurs to annoy them. Perhaps there may be an affectation of indifference in this; still their conduct is worth admiring, for every thing like fidgetiness or boisterousness of manner is disagreeable to all who witness it.

Carefully avoid the following things in personal behaviour:—Loose and harsh speaking; making noises in eating or drinking; leaning awkwardly when sitting; rattling with knives and forks at table; starting up suddenly, and going unceremoniously out of the room; tossing any thing from you with affected contempt or indifference; taking any thing without thanking the giver; standing in the way when there is scarcely room to pass; going before any one who is looking at a picture or any other object; pushing against any one without begging pardon for the unintentional rudeness; taking possession of a seat in a coach, theatre, or place of public meeting, which you are informed belongs to another; intruding your opinions where they are not wanted, or where they would give offence; leaving acquaintances in the street, or a private company, without bidding them good-bye, or at least making a bow to express a kindly farewell; slapping any one familiarly on the shoulder or arm; interrupting any one who is conversing with you; telling long and tiresome stories; whispering in company; making remarks on the dress of those about you, or upon things in the room; flatly

contradicting any one, instead of saying, "I rather think it is otherwise," "I am afraid you are mistaken," &c.; using slang expressions, or words of a foreign language; acquiring a habit of saying, "says she," "says he," "you know," "you understand," &c.; helping yourself at meals without first asking if you may not assist others to something which they would like; picking your teeth with your fork, or with your finger; scratching or touching your head; paring or cleaning your nails before company; mentioning the price of any article of food or drink which you are offering to guests; asking questions or alluding to subjects which may give pain to those you address; neglecting to answer letters. It would be easy to enumerate many other things which should be avoided as savouring of bad manners, but these will be sufficient to indicate the principle of politeness, and if that be understood, there can be no difficulty in knowing how to act with delicacy and discretion in all the concerns of life.

4. *Gentility and vulgarity.*—By attention to the rules of good breeding, such as we have just alluded to, the poorest man will be entitled to the character of a *gentleman*, and by inattention to them the most wealthy individual will be essentially *vulgar*. Vulgarity signifies coarseness or indelicacy of manner, and is not necessarily associated with poverty or lowliness of condition. Thus, an operative artisan may be a gentleman, and worthy of our particular esteem; while an opulent merchant may be only a vulgar clown, with whom it is impossible to be on terms of friendly intercourse. Vulgarity of manner is often exhibited, in its most offensive form, by persons originally of humble birth and breeding, who have risen to wealth by the force of fortuitous circumstances. It is not uncommon to hear persons of this class, particularly "ladies," speaking of "my coach," "my house," "my governess," "my family," "my servants," "my furniture," and so forth; all which is *pure vulgarity*, and indicates a low tone of breeding, and weak understanding on the part of the speaker. A man or woman of refined taste never alludes to matters of dress, domestic convenience, or things strictly personal, and rather endeavours to direct conversation into those channels in which all may harmoniously join.*

ANGER.

One of the most important of our private duties is the due regulation of the passions. We naturally possess certain mental affections called *propensities*, which, when properly restrained, serve a good purpose, both individually and socially, but when let loose, or badly regulated by the understanding, lead to the commission of many vicious and abominable actions, which in moments of calm reflection, and when our conscience is aroused, we deeply lament and regret. Irritability of temper, as demonstrated in the passion of anger, is one of the most unhappy of these derangements of our intellect.

The causes of anger are supposed to be these:—First, by the law of nature and of society, every one has rights in what he regards as his own property; second, one has a right to hold unimpaired whatsoever he can justly acquire in reputation and character; third, he has a right to have his feelings respected by others, if he do no wrong to their feelings; fourth, he has a right to have the like rights respected in those with whom he is necessarily connected by family and social ties; fifth, he has a right to be treated with justice, and according to established laws, by those who are intrusted with power; sixth, he has a right to have those who are bound with him, in a common subjection to such laws, treated with justice. Whenever any one is offended by the violation of any of these rights, he may be justifiably angry. But in what manner, and to what end, he shall express his anger, so as to do himself the greatest justifiable good, is the thing to be known.

Every one who has had a violent fit of anger upon him, knows that it was to himself (independently of the cause and object of his anger) a painful and even a very

distressing sensation. No one ever looked back upon such a state of things, as to himself, with satisfaction, but generally with regret, and sometimes with remorse. He feels humbled and grieved in his own estimation of himself. He may too well remember that he used expressions and did acts which he is grieved to have resting in the memory of others, or in his own. It is probable, also, that no one ever saw another in a violent passion, without feeling that this angry person was degrading himself, and acting more like a brute than a rational being. Whatever be the cause of such anger in another, cool spectators always regard the angry person as under a temporary loss of reason, and in danger of doing some serious mischief, and are prompted to restrain him. Every one feels, in such a case, that the least that can happen to one so acted upon, and so acting, is, that he is preparing for himself hours of self-reproach and of bitterness. If no one likes to remember that he was violently angry himself, and if he is offended in seeing others so, it must be admitted that violent anger is contrary to natural law, as it most certainly is to divine law. It is an abuse of the trust confided to us to promote our own welfare.

It is consistent with reason for any one, who is under the influence of anger, to be prepared to ask and answer the question, whether the wrong is real or only supposed, and whether he is himself free from the first imputation of having occasioned, by his own error, that which he regards as a wrong. If the offence is real, other questions arise, of this nature: What real good shall I secure to myself by attempting to get a reparation? and in what respect shall I advance my own welfare by attempting to punish the offender? May I not, in either of these attempts, involve myself, by words or acts, in some wrong, and give my adversary the advantage of finding me an offender, in trying to vindicate myself? If I could succeed in my attempt, what will it come to? Shall I not make the wrong done to me more notorious, and subject myself to the pity and compassion of others? Is it not better to be silent, and quiet, and leave the offender to time and his own conscience, than to engage myself in a controversy which is sure to be vexatious, and in which I shall run the risk of doing wrong, and in which I shall not be likely to get any good? If I succeed in humbling my adversary, I shall surely make him my enemy for ever; for, in the nature of man, he is slow to forgive the wounds inflicted on his own self-love. When this matter is over, and time has dissipated the mists which now prevent a clear view of it, and when other feelings and sentiments have arisen, shall I like myself the better for having been silent and quiet, than if I shall have attempted to command justice and to inflict punishment? It is probable that young and ardent minds, and those who are looking back by the light of experience, will answer such questions very differently. But the experienced can tell the young, with sorrowful truth, that among the most painful sufferings of life are to be numbered those which have arisen from sudden impulses of anger, expressed in words or acts. The experienced can also tell, with like truth, that in the common occurrences of life, angry words and acts have seldom, if ever, accomplished the purpose for which they were intended; they have neither obtained justice nor punished the offender; but, on the contrary, they have often converted the injured party into an offender himself, and involved him in bitter recriminations, keeping up an irreconcilable aversion, and even enmity, through life. We have, so far, supposed that a real and justifiable cause of anger existed. But it is in many cases imaginary, especially among young persons. They take up sudden impressions concerning the supposed conduct and words of their associates and acquaintances, when no such conduct or words have occurred; or, if any did, none with intention to wound or offend. If there be one case in which one feels himself peculiarly humbled, it is when he has manifested anger towards one who has committed no offence, or who is entirely unconscious of having done so.

* The above section has been written by one of the editors.

It sometimes happens that an offended person can restrain himself from expressions and words when he has been seriously offended. But he cherishes a malicious sort of feeling against the offender, broods over the wrong done, and permits his imagination to inflame the sense of wrong, until he makes himself too unhappy, under this excitement, not to express it in some mode which will occasion pain or affliction to the offender. If there be any one who has fallen into such a condition, he may be asked, whether he knows of any thing in the nature of regret or remorse for his own follies and sins, which is so exceedingly burdensome as to carry about with him the feeling of aversion, ill-will, and malice, towards one who has offended? What, then, is to be done? angry words and acts are forbidden by the law of nature, by self-respect, and by convenience; the memory of an unavenged wrong is intolerable. Is there no remedy? We think there is one in every person's power. If the individual with whom one is at variance can, by calm expostulation, or by mutual friends, be brought to a just perception of the case, that is the remedy. If that fails, there is another; it is of high authority: "if thine eye offend thee, pluck it out." Blot such a person from the memory; never permit him to come into your thoughts. Will you pass your life in humiliating bondage to such an one? We say, *blot such an one out of your memory.* You do him no wrong by that. You do yourself a just and great good; you cut a moral cancer out of your heart.

Among the sources of affliction in human life, is the uncalled-for interference of third persons in the angry collisions of others. It may sometimes be an unavoidable duty to take a part in an angry quarrel. When this duty is to be performed, it concerns every one who is mindful of the trust confided to him of taking care of himself, not to engage in the controversy in such a manner as to become a principal party in it. As a general rule, it is the safe course to let angry persons settle their own concerns as they can. Certainly, no one who claims to be regarded as having a discreet sense of his own welfare, plunges himself into a quarrel. Yet this is a very common thing. It is often seen in schools. Parties and divisions grow up, extend, and become more and more bitter, from the most trifling causes, and are often carried out into manhood, and show their evil consequences through life. This is so, because impressions made in that season are very vivid and durable. It is a duty sometimes to take a part in controversies. It must be remembered, when one engages in such quarrel, that one is dealing with persons who are under a sort of derangement, and who are most exceedingly sensitive, and perhaps mutually vindictive. Those who interpose are bound, by the law of self-regard, to interfere with calmness and sound discretion, and so to conduct themselves, in word and deed, as to do no evil to themselves while they attempt to do all the good possible to the angry parties. On the whole, mismanaged anger is a prolific source of suffering. Yet when calmly looked back upon, in a great majority of cases, the cause was some insignificant trifle, magnified into serious importance by angry words and pitiful acts. Such is the propensity of persons to busy themselves in the quarrels of others, that there is little reason to hope that a preventative can be successfully offered to any but to those who have studied out and who reverence the will of the Deity, as disclosed in the nature of things, and in his own positive law.

SELF-RESPECT.

Every one has some sort of opinion, more or less distinct, of all persons with whom he is acquainted. This opinion may embrace intellect, disposition, virtues, vices, personal appearance, deportment, condition in life. So also every one has some opinion of himself on the same, and on many other subjects best known to himself. When one examines his own opinion of himself, he seems to do it as though he were another person. He uses the eyes of others. He turns aside, as it were, by the way, to see himself pass by. The judgment

which one forms of himself is often much more unsound than that which he forms of others. The eye cannot see itself; so neither can any one see himself. He must use a mirror. There are many of these. History, books, daily example, his own experience, every person he comes in contact with, are mirrors. If he sees himself in these, and thereby corrects his own errors and follies, and gives himself reasonable and just credit for his attainments, he may come at length to be entitled to entertain a respect for himself. There is a certain best thing to be done, and a certain best manner of doing it, in all possible circumstances in which one may find himself. Nothing is entitled to be considered *best* which does not conform to natural law, the law of God, the positive law of the land, the conventional laws of society (so far as they are founded in reason and good sense), and to the decencies of life. To that best thing, and to that best manner, no one, perhaps, ever perfectly attains; but it cannot be doubted that there is some such standard. He who comes the nearest to it is he who is best entitled to entertain a respect for himself.

PRIDE.

There is a kind of pride which is often mistaken for *self-respect*. We hear of honourable and of laudable pride. We take pride to be that self-esteem in which a man holds himself. It may be founded in his estimation of the qualities of his mind, in his attainments, in his possessions, in his strength, his beauty, his parentage, and descent. It may also be founded in a consciousness of virtue, and of having faithfully done one's duty in all the relations of life. It seems to arise necessarily from comparing one's self with other persons. If this be the right meaning of pride, it is very clear that it is not always a sentiment which entitles one to respect himself. A man would be thought to be very unwise who should openly declare that he valued himself, in comparison with other men, on account of his wealth, his beauty, or his family connexion; equally unwise, if he should declare his opinion of himself to be, that he was superior to other men in the gift of natural intellect, in the cultivation of it, or in the practice of the various virtues. The common sense of mankind, founded in natural reason, does not approve of that self-gratulation which rests on the accident of birth, of inheritance, or even on the acquisition of fortune by one's own industry; nor does it approve of that feeling, when founded on qualities which belong to the mind, nor even in the practice of the virtues, unless when manifested in a certain manner. There must be, in the very nature of things, some persons in every community, large or small, who are superior to others in these sources of self-esteem. In every city, town, and village, in this nation, there are some persons who are in possession of some of these causes of self-esteem in some comparative degree, and other persons who have the fewest or the least of them. Those who so use their advantages as to entitle themselves to the esteem of others, and who are acknowledged to be respectable for that use, may well be entitled to respect themselves from such causes. Those who use them in such a manner as to announce the feeling of superiority over others, and habitually to offend the watchful feeling of self-love, are properly called *the proud*. It is believed that these views conform to natural law, and to the necessary constitution of human society.

VANITY.

A still greater mistake is made in substituting vanity for self-respect. The word vanity is made out of two Latin words which signify *exceeding emptiness*. It is commonly understood to mean a strong desire to be noticed, considered, and esteemed by others, but on account of things rarely worthy of a rational mind. Vain persons covet praise. They thrust themselves, and all on which they value themselves, upon the notice of others. They delight in recounting their achievements, and sometimes make the sad blunder of speaking to those who know they are mistaken. They touch

adroitly on their own excellences, and provoke others to descant upon them. They have such delightful visions of self-complacency, that it seems cruel to disturb them. Such persons are very ready to become tools in the hands of more knowing persons. In general, the display of this poor passion is made by persons of very light and frivolous minds. It is seen at all ages, but strikingly in youth. To see a young person strutting or mincing along in a new garment, or in some personal ornament, and watching to see if he is noticed, and by whom, excites a feeling of pity and contempt. The same feeling arises when young persons are seen, who say in their movements, as intelligibly as though they spoke in plain English, "Do they not think me very handsome—elegantly dressed—a charming figure—most exceedingly graceful?" In some instances lookers-on do think so, and smile contemptuously at the same time. But, in general, lookers-on see no such thing as the vain imagine; they do see that which it would be shocking to those votaries of vanity to know is seen. They do see talents wasted, time misspent, foolish hopes, and vain desires. They do see that the purposes of life are misunderstood or perverted. Is there any remedy for these follies? None, probably, unless one would bring home to the minds of the vain, that they violate the strongest precept laid down in the code of natural law for the government of persons individually and socially. That precept commands them so to conduct themselves in all things, as to entitle themselves to self-respect, and, consequently, to the respect of others. If the vain could conceive how small a portion they make of created being, how insignificant a part they make of civilised society, how many there are in that society, whose pretensions, if asserted, would be transcendently superior to their own, they might, perhaps, dismiss their little vanities, and devote themselves to gratifications worthy of their intended nature.

GRATITUDE AND INGRATITUDE.

If a destitute young person should attract the notice of a wealthy man, and should be by him supported, educated, and established in the world, so as to be able to live, to become independent and respectable, every one would say that this is a case for the feeling and the expression of fervent gratitude. Let us suppose that the patron of this young man frequently reminds him of his former condition, and by what means he finds himself where he is. Suppose the patron exacts a frequent acknowledgment of his bounty, and takes to himself unqualified praise for his goodness. Let us suppose that the obliged party finds his condition very irksome, and almost wishes that he had never been the subject of such burdensome favour, and is at length provoked to say so—*is he ungrateful?* It would seem, then, that gratitude had two sides to it, as well as two parties. He who has conferred a favour has not done all which it concerns him to do; and he who receives a favour may have a difficult task to perform. A bargain is an exchange of one thing for another, and the parties are even. The conferring of favours, whether these be asked for or not, seems to stand on very different grounds. Many elements make up that compound from which gratitude is said to arise. The parties may understand the nature of the favour very differently at the time when it is conferred, and more differently afterwards. He who confers, has a retentive memory; he who receives, a fading one: time engraves the favour deeper and deeper in the former, and wears it out more and more in the latter. In the former it often preserves the freshness of a new occurrence; in the latter the sense of favour often goes, and the weight of obligation alone remains. It may be that the complaints made against ungrateful persons are not always well founded, and that the expectations of those who confer favours are as little so. Some poet has written,

If he that's ungrateful has an only fault—

All other crimes may pass for virtues in him.

The meaning of this couplet must be, that the members

of society are under no obligations to confer favours, and that, if they do confer them, the party obliged is a monster if he do not—*what?* We know not what is intended, nor that there is any rule by which gratitude is to be manifested. We think that every member of society is to do what of good he can, and to whomsoever stands in need of it. He is not to stop to measure and calculate how he is to be paid for it. He may not be paid by the party benefited directly, but by some other, and in some other and unexpected way. Whosoever confers favours, opens an account with the changes and chances and accidents of life. His credit side will look well in the close. If he confer a favour, he does it because he thinks he can and ought to do it. He has the pleasure of doing it. If he wishes to avoid the affliction of ingratitude, he has only to avoid letting the party obliged know, unnecessarily, whence the benefit comes. When a favour is done, the party conferring it takes on himself the duty of respecting that feeling of the human heart which is founded in reasonable self-love, and which is entitled to respect—that is, *not to ask one who has had the misfortune to be bound in chains, to clank them for the gratification of him who put them on.* There are cases of extreme ingratitude. They may have been occasioned by the irritating or indiscreet conduct of the party who was entitled to a different return. They are not of common occurrence. When they do occur, uncaused, the disappointed party may hope to find a better subject in his next essay.

SLANDER.

This is a twofold crime: 1. It is a breach of natural law, of divine law, and of the implied law of society, in relation to the party spoken of; 2. It is a breach of the same law, in relation to the party speaking. It has been commonly treated of in the first relation. It is now to be noticed in the second; and if it be shown why it is a breach in this, the other will take care of itself. We beg leave to ask a slanderer a few questions: Do you desire to be esteemed in society for your intelligence, your sense of justice, your knowledge of the decencies of life, and for the observance of them? If you happen to be ill-tempered, petulant, and disagreeable to your family connexions and associates; if you make hasty and troublesome judgments, which you have to rescind or reform; if you happen to be ridiculous in your deportment, and remarkable for silly vanities; are you willing to have these things set forth in any, and every company, by any one who knows of them? Suppose there to be only some slight foundation for some one or more of these things, which, if you could have an opportunity to explain, would be entirely cleared up, are you willing to have that slight foundation made the basis of a structure of reproach, which, if true and real, ought to expel you from decent society? Suppose there to be no foundation at all for any such accusation of yourself, and yet somehow, and unaccountably, it is afloat and circulating, should you not think great injustice to be done to you? This is just what you do to others. You take away their good name, if they deserve to have one; you magnify their little faults and errors, and make them ridiculous or odious; you try them on indictments for serious offences, on which they have no opportunity to defend themselves, and of which they are ignorant. Where did you get your information? What credit were they entitled to from whom you had it? Did you understand them as they meant to be understood? Where and how did your informants learn what they communicated? Were they thoughtless or malicious slanderers like yourself? How much have you added to their slanders by way of recommending and making yourself agreeable? Have you broken any law by this conduct? We take the liberty to answer for you.

You have broken every law which an honest and honourable man, and a rational individual, should respect. 1. You have made every person whom you have spoken to, fear you and shun you. You have shown that you know not what the value of a good

name is, and have forfeited your own, if you ever had any. You have shown that you are a stranger to self-respect; that you have probably every one of the faults, follies, and errors, which you impute to others; and desire to bring them down to your own level. Thus you have broken that law which commands you to do no evil to yourself. 2. You have violated that principle of natural law which commands you to do no injustice to your fellow-men. You know not what opinions you may entertain of the party you have slandered, if circumstances (as they may) should bring you into connexion with him. You may find him to be, on a better knowledge of him, an amiable and worthy person. You may find all that you have said, and helped to circulate, utterly groundless. If he be one whom you occasionally meet, and even ask to partake of your hospitality, how can you meet him, and manifest towards him every sentiment of respect and esteem, when you have so spoken of him? One of two things must be true: either you *act a lie*, when you meet him in such a manner; or you *spoke a lie*, when you represented him as you did to others. 3. You have broken the law of God. To this law, perhaps, you are a stranger, and know not what wrong you have done. If so, the kindest thing that any one can do you is, to urge you to find out what it is, and to learn there the sentence of the slanderer.

It may be asked, whether one is to be entirely silent at all times, and on all occasions, as to the character and conduct of others? Certainly not. There are many occasions for speaking of others, and for speaking the *truth* of them, whatever that may be. All the members of any community are interested in knowing the true character of each other. The knowledge that this character may be known, is one of the most salutary correctives of erroneous conduct, and one of the strongest inducements to pursue that which is commendable. It is probably the case, that the members of every community are pretty well understood by all who have an interest in knowing them. We know not of any law which holds it to be immoral to *speak the truth of any one, from good motives, and for justifiable ends*. It is all-important that this principle should prevail in our country, where so much depends on public opinion. Surely one's arms are not to be folded, and his lips closed, when he sees one bent on mischief, public or private. It may be one of the highest moral duties to declare what men are, and what they are aiming at, in many supposable cases. There can be no surer guide than the *motive* and the *end*. Inquiries are sometimes made, in matters of greater or less interest, concerning others, confidentially, and where the inquirer needs to be truly informed. The party inquired of has a right to be silent, if he thinks he has good reason to be so; but if he answer, he is bound to state the truth. If he choose to speak, and wilfully conceal the truth, so that the inquirer is deceived, he subjects himself to the imputation of an intentional deceiver.

There may be also, and there frequently are, confidential discussions of character, especially concerning public men, and where perhaps there is no particular end in view. This does not seem to be wrong; such intercourse is not founded in malicious or unworthy motives. It is even sometimes instructive and philosophical. This, perhaps, is the extreme limit. In all other imaginable cases, it is probably most consistent with one's own self-respect, and all truly respectable motives, to let other persons alone, and leave to them the care of their own characters.

PROFANITY.

Excepting the high crimes which are punishable by the public laws, there is no one so shocking as *profanity*, nor any one which there is so little inducement to commit. Profane swearing is of two kinds: 1. That in which the Deity is called on to do the pleasure of a sinning mortal; 2. That in which the Deity is called on to witness the truth of such a being's thoughtless or wicked declarations. This common practice can be accounted for chiefly on two grounds: 1. Pitiable igno-

rance; 2. Abominable wickedness. On the first ground, surely the profane swearer must be ignorant of the import of the terms which he uses. If he did understand his own words, he would be struck with horror. Surely, if there be any escape for the profane from that condemnation which they imprecate on others, it must be, that mercy will be extended to them in compassion for their ignorance. On the other hand, if they are not ignorant, but do knowingly and wilfully so misuse the gift of an immortal mind, and that unquestionable proof of Divine power and goodness, the *ability to speak*, they cannot be subjects of moral instruction. They should be left, like the consumers of alcohol and tobacco, to shock and to warn others.

Swearing, which formerly pervaded every rank of society, is now to be chiefly found in a very low and uninstructed class: it is, in fact, a vulgar and proscribed mode of speech. Nevertheless, it is still used occasionally by persons of no humble rank, especially by the young, though chiefly for the purpose of giving an emphasis to speech, or perhaps simply to give token of a redundancy of spirits, and a high state of excitement. To those who are guilty of it for these reasons, it is only necessary to point out, that no well-informed person can be at the least lost, with the genuine words of the English language, to express all legitimate ideas and feelings, and that to use either profane or slang words, is, at the very least, the indication of a low taste and an inferior understanding. A direct, pure, manly use of our native language, is an object which all may cultivate in a greater or less degree; and we have invariably observed, through life, that the most virtuous persons are the most exempt from the use of mean and ridiculous phraseology, and monkey tricks of all kinds.

Does not one who is habitually profane, necessarily entertain a low opinion of himself? Would any respectable merchant, or mechanic, or farmer, receive into his service a youth whom he knew to be a profane swearer? Could any one who is known to be such, find admission into any school, academy, seminary, or college? Would any respectable parent admit such an one to be a companion of his children, or a visitant in his family? Would not every reasoning person say, that a youth who is so ignorant as not to know that swearing is a violation of natural and divine law, must be ignorant enough not to know that there are many other laws for the proper government of society, and consequently that he is an unsafe person to be trusted? If the profanity be the consequence of voluntary wickedness, then surely all reflecting persons would say, that he who is wicked in this respect, is indeed wicked; but then he will be wicked in others also. For, as there is one chain which runs through all the virtues, and binds them in a sympathetic union, so also is there a chain which unites all the vices. He who swears, may be justly suspected of drinking; he who swears and drinks, may be justly suspected of gaming; he who swears, and drinks, and games, must keep very bad company by day and by night. He who keeps such company from such motives, must squander his own property, or steal that of somebody else to expend. He who robs another will commit forgery, and he who is so desperate as to commit these two latter crimes, will not hesitate long to put a human being out of the way of his pressing wants, if he is tempted to do it. It is probable that habitual lying and swearing are the first steps in that mournful series of crimes, and the first beginnings in the course of deplorable wretchedness, which deform and disgrace human society. Will any one maintain that these are necessary evils, and that God has so made man that they cannot be prevented? Surely these are evils wholly of human origin; and where they begin, there lies the power to extirpate them.

ENVY.

It is to be kept in view, that the main object is to show that this is a good sort of existence, if man knew how to use it, and that he is the author of his own af-

fictions. This is remarkably illustrated in the matter of *envy*. It is probable that a large proportion of mankind, in all classes, suffer from the dominion of this passion. It can be shown that it is peculiarly the passion which man has made for himself out of emulation, which latter is the Creator's work. In this instance, man has been exceedingly ingenious and successful in making himself miserable. He has done worse; he has provided for himself, in creating envy, a fountain which sends forth not one water, but many, and each one foul and poisonous. He who has submitted himself to envy has bound himself to think, to feel, and to act, as envy prompts. It would be most shocking to know what agency this monster has had in human affairs. If any one should read history, and watch the movements of his fellow-men, merely to learn the operation of this principle of action, he would see, probably, the most operative cause of the misery which men inflict upon themselves and on each other. If one has not time to read history, and watch his fellow-men, he may perhaps learn much of what he would find in these authorities, by *reading his own heart*.

The word *envy* comes from two Latin words, *in* and *vidio*, and signifies *looking against*. It arises from perceiving in other persons, qualities which one's own self-love leads him to wish to have—as beauty, strength, grace, learning, eloquence, power, &c. It extends to riches, to office, to distinction, to the respect and esteem in which one is held by his fellow-men, and even to birth and ancestry. It makes one *sorry* that he has not these good things, and makes him *angry* that others have them. One easily persuades himself that great injustice is done to him, in that *he* has them not. The next step is to *hate* him who has them. Then comes the desire to deprive the supposed fortunate possessor of the benefit of them. But to admit that one has these malignant promptings, is contrary to another principle of self-love; and therefore no man tells another of his own envy, and he tries to wrap it up from his own view. As he cannot and dare not openly manifest that he is envious, he must obey the suggestions of malice in the dark. He therefore intrigues, insinuates, and becomes adroit in putting one thing for another; he secretly and by covert means undermines the object of his hatred. He whispers his doubts, suspicions, opinions, and belief. If the tenure of the hated object is too strong to be shaken, then the bad use which he makes of his advantages are sought out. The base accompaniments of his fine qualities are brought forth, and placed in the strongest light. “She is beautiful; *but* she is vain, haughty, and silly. He is rich; *but* he got his wealth by frauds, and hoards it like a miser. He is able, eloquent, and popular; *but* he is selfish and insincere, and would put a yoke on every neck in the country if he could. He is making a great flourish in the world; *but* it is all false and hollow—he came from nothing, and will go back to nothing.” It may be easily inferred that one who has surrendered himself to the dominion of envy, not only deprives himself of the profitable use of what he has or might have, but makes himself wretched in contemplating what he must know he cannot have: he is so wrought upon, that whatsoever seeds of crime he may have in his heart, are sure to start into luxuriant growth.

Can any rational being doubt that this sort of suffering and crime is entirely of man's making? Can it be doubted that he can prevent them? These are violations of natural law and Divine law; and no law comes from this source which cannot be understood and obeyed. Let us take an example, and seek out the unreasonableness and immorality of envy; and to do this effectually, we must take a strong case, and in some degree a fanciful one. Let us suppose that in a seminary of females there is one who is very beautiful; her parents are very rich, and are highly respectable; and that this young lady is distinguished by her genius, and her diligence and good conduct, and is obviously in the receipt of the preceptor's unqualified approbation. Let us further suppose that there are some of her school-

fellows who *envy* her. Their countenances show what they feel. Every mark of favour manifested to this fortunate person is a blow on every envious heart. Discontent, distress, and malignity, take up their abodes in these hearts, and enter into thriving partnership. But the beauty, the genius, the diligence, the wealth, the parentage, the applause, are not among the dividends which these partners make: these remain where they were: and what dividends do they make? Let us suppose that the envious would do what they would; that is, annihilate the envied qualities, and make the possessor too low and contemptible to be more thought of; and let us suppose, too, that the successful adventurers succeed to what is now the first eminence—is there no one below to pull them down? They are soon down, and by like means; and thus the demolition would descend, until the seminary became too low a place for even envy to find something to live on.

Is not this a fair example of what we continually see in all grades and classes of social life? and is not this passion of envy, earth-born, mischievous, and odious? What is the remedy? Common sense and plain reason point out the remedy. Generally speaking, every member in society is just as much in his own place as he is in his own skin. No one can be in another's place. Every one has his place originally assigned to him, and his natural condition in it, by means over which he had no control, and in making which he had no agency. What he will make out of himself, and of the circumstances in which he finds himself, must depend (after the irresponsible state of infancy is passed) on his own thoughts, motives, and acts. He will find his greatest good, not in repining at the good of others (which he can never make to be his own, and which he cannot destroy without expecting retributive justice as to himself), but in making his own condition as good as he can, consistently with self-respect and peace of mind. That which is given to others, and all that they can lawfully acquire, is righteously their own. All that is given to one's self, and all that he so acquires, is in like manner his own. If he would have no injustice done to him by those who are below him, he must do no injustice to those who are above him. We entertain no doubt that the day will come when youth will be so instructed, and men so self-disciplined, as to know that the laws of nature, and the laws of society when conformable to these, permit to every person a proper place, enjoin duties in that place, and ensure happiness from the performance of those duties. When that day comes, envy will die.

EMULATION.

This has been sometimes classed with envy, but they have nothing in common. One would feel like a culprit in being known to be envious, but would rightly take praise to himself in being emulous. This motive to action was given to man for the best possible purposes; and upon the application of it, with justifiable views, and to commendable ends, the advancement of human welfare mainly depends. We understand it to mean, the desire to obtain excellence in laudable pursuits. An envious man may be supposed to say, “Your eminence distresses me; I cannot bear to see you sitting up there; and though I have not the shadow of hope that I can ascend to your place if you were out of it, nevertheless I must pull you down if I can; and then we shall stand on the same level.” An emulous man may be supposed to say, “I admit that you are where you should be. You have raised yourself by fair and just means. I have no desire to disturb you, nor to impede your further progress. You have done me no injustice; on the contrary, you have rendered me the important service of showing me how one may honourably rise. I shall follow your example, and endeavour to place myself by your side. If I can get there, we shall have a fair, good-tempered rivalry, and we may animate and quicken each other's efforts. If you are able to keep always in advance of me, you will make me diligent, and enable me to excel others, if I cannot

equal you." There seems to be nothing immoral in this. In this view, emulation is presented in its true and amiable character. Like every thing else intrusted to man's use, it may be, and often is, perverted. It frequently excites very unworthy feelings. Hence it has been confounded with envy. It is upon the principle of emulation that diligence in schools is commonly founded; and it is in schools that the perversion alluded to is frequently noticed. When several children are required to get and recite the same lesson, there must be a best and worst among them. That they are such respectively, may depend on natural talent, and upon industry, or on both. It deserves great consideration, whether rewards and punishments are generally understood in their true philosophy. There must be emulation in schools; because there is, and ought to be, that stimulant every where in all the vocations of life. If men had not the advantage of comparing themselves with each other, and the promptings to exertion which arise from that comparison, this life would be very still and stupid. But what use is to be made of this principle in schools? is a question of exceeding interest. We express no opinion on this point, because we might not express a sound one, and might thereby do some injury, and very possibly no good in any case. Add to this, that such an inquiry does not come within our general object.

PEACE OF MIND.

It is believed that most persons pass a large portion of their lives in a state of inquietude and uneasiness. Persons who have no bodily disease are anxious and disturbed. They have some urgent want which cannot be gratified, or which cannot be so without incurring some evil which would be worse than the unsatisfied want. They have the dread of some probable or possible evil to come, and which is the more terrible because of the uncertainty of the manner and of the time in which it may come. Others are uneasy from remembering the past, in which some benefit was not secured, some blunder made, some wrong done to themselves, some vain gratification not obtained. There are many persons who are habitually discontented. They find every thing goes wrong. The weather is bad; their food is not as they would have it; no one does any thing in the right time, or right manner; or that is done which should not be, or that is omitted which should be done. Such persons are always groaning, sighing, or grumbling. They dislike every body, and every body dislikes them; and particularly, their abundant *advice* is disliked, and their manner of giving it. There are other persons who are of unquiet mind for more serious causes. They have recollections which distress or torment them. They are transgressors; perhaps criminally so. They have been able to conceal this, but they live in the fear of disclosure; at any rate, the fact cannot be hidden from themselves.

These are frightful instances of the agency of this companion which every man has in his own bosom. There are hours in every one's life, when he must compare the condition in which he is with that in which he thinks he might have been. To some persons, these are hours of dread and terror. It is believed that this cause of suffering is purely of human origin, and that prevention must be found where the error began. It is the law of the Deity that there shall be such suffering when the guilty mortal makes it necessary to apply that law. There are great differences in the temperament and natural dispositions of persons. It is incredible that the worst-tempered persons would not make a better whole of life, by suppressing their natural propensities, and acquiring a control over themselves, and teaching themselves to look out for what may be pleasant and agreeable (passing by that which seems ill to them), instead of doing exactly the reverse.

There are cases in life in which it is said there must be anxiety and inquietude, from the very condition in which men are placed: persons who sustain public offices, persons who are placed in important trusts,

persons whose vocations are perilous, those who are pricked by the thorn of political ambition. It is probable that such persons do experience many painful and distressing emotions, and that they sometimes pay dearly for their distinction; but it is demonstrable that even such persons might have tranquility, if they had a right frame of mind. There are persons who substitute an aching solicitude for the reasonable discretion and care which is all that is required in the performance of duty. There are others who greatly overvalue the distinctions to which they attain or aspire; and very few of them reflect, that, when they do succeed, they must take success, especially in popular governments, with the accompaniments of having their worthy acts misunderstood and reproached, and their mistaken ones magnified and distorted, to suit the occasions of adversaries.

The remedy for this sort of suffering is within every one's power. Those who are poor, and in humble life, if not in extreme poverty, may possess peace of mind; and it is of easier acquisition by these than by those who are involved in the duties of office, and the responsibility of trust, and the embarrassment of wealth. Certainly, without this treasure, no earthly grandeur, no promise of posthumous glory, is worth having or seeking for. If the laws of nature, and the teaching of revelation, were properly known, respected, and obeyed, the common causes of inquietude would hardly be known. For example, what is more common than complaints of the weather? It is too hot or cold, wet or dry. It is not nature that mistakes about the weather, but ourselves. The movements of the winds and the waters, and the temperament of both, proceed on some great and universal laws, far beyond human perception. That which is exacted of us to believe is, that it is so, and to adapt ourselves to it, by our experience and ingenuity. What sort of effect would it produce in the earth, if such things were regulated by human perception of what is best? When one has occasion to put to use a board or stick of timber, which has been in contact with the ground for a certain length of time, he disturbs and puts to flight families, communities, and whole nations of living beings. Man may be much in the same relation as to general laws (not meant for him to comprehend), in which these insects are on the removal of their covering.

As to all causes of inquietude arising from the operation of nature's laws, in which human agency has no concern, they must be right, although they occasion inconvenience to individuals. As to the acts and omissions of others which affect us, some questions are to be asked and answered before one can rightly judge of these; namely—What is the real cause of our complaint? Did not the first fault arise from some act or omission of our own? Do we judge reasonably of the supposed wrong? Do we make charitable allowance for the misapprehension which may affect the party complained of? When the inquietude arises from our own wayward and peevish disposition, from our own misconduct, negligence, or breach of laws, which we could know if we would, the remedy lies in becoming wiser and better, and more reasonable in learning how we may make of life that which it was intended to be, when we use it as we should. Let any reasonable being look back on his own life, and calmly consider the causes of his own contentions, ill-will, and sufferings, in body and mind; how many of these can he fairly lay to the blame of the Creator's laws, of nature's laws, or those of society, whether positive or implied? If to these he can charge but very few, who but himself is there to take the residue?

We have been trying to show what peace of mind is not. We have to show what it is, or rather in what it is founded. It comes from sober conviction that the Creator has made his own laws for his own universe; that he requires conformity to these laws; that he permits and enjoins the use of what is good and right; that he punishes all that is wrong and disobedient. He has trusted every mortal with his own welfare, but

has associated him with others who live in the same trust, each one for his own, but yet for mutual welfare. All are to contribute their common efforts to the common good. Those who have the means are to aid others in acquiring a knowledge of the laws which are common to all. If these laws were understood and applied, how abundantly would peace of mind increase in the world! The schoolboy would get his lessons and obey his preceptor; the labouring classes would labour diligently, live temperately, and find a greater pleasure in their frugal food than the luxurious in their festivals; for the former live as nature orders, the latter as fashion dictates. The opulent and luxurious would learn that the accidents of their fortune do not exempt them from the laws of nature; that, if they have affluence beyond their reasonable and commendable wants, they are blessed with the means of purchasing a precious name; they would learn that no wealth will exempt any man from earning an appetite for his pleasures by physical motion; that, if he is tired of being rich and happy, *he must work* to accomplish some reasonable purpose. His distinction is, that he may choose the means in which he will expend to be busy, while others can only work in some prescribed mode to live.

The middle classes, and all who are not dependently poor, have as many and as valuable sources of enjoyment as those have whom they think to be better off than themselves. They can love and be loved; they can be respected and esteemed; they can have the consciousness of behaving well, where their lot has been cast; they have a far keener zest for natural and reasonable pleasure than those who misuse the bounties of accidental condition; they can have peace of mind when it is denied to those whom they deem more fortunate. If these natural laws, which seem to be so plain and obvious, were understood and respected, the labourers *in mind*, in all their varied employments, would do diligently, and in the best manner in their power, that which they have undertaken. Men of public trust would do honestly, and with a single view to their trust, that which they have undertaken. Suppose it were all so, and yet troubles and disappointments come. This may be, and yet there would be peace of mind. If every one were assured that no act, no omission of his own, makes him suffer, that he has acted faithfully and honestly, and to the best of his ability, in the circumstances in which he was placed, he would be entitled to have, and by the law of immutable justice, he would have, *peace of mind*.

HAPPINESS.

There is no word in our language more commonly used, nor any one less defined or less understood. It is sometimes taken to mean pleasurable sensations derived through the senses; sometimes it means a peculiar state of mind. It may be said that a pirate who has been brought to the most perfect penitence, and who is sensible that he has forfeited his life to the demands of justice, and that he is about to be transferred from the perplexities and sufferings of this state of being to endless felicity, is *happy* that he is going to be *hanged*. Perhaps it is easier to tell what happiness is not, than what it is. The most perfect *health* is not happiness, unless one has something to do. *Health* and *riches* do not make one happy. These accidents of being rather excite cravings for enjoyment. They are means, not ends. A rich man can ride but one horse, or sit but in one coach, or eat but one dinner, or wear but one suit of garments, or live but in one house, at a time. Persons in moderate circumstances can do the same.

Health, riches, *power*, and *distinction*, do not make happiness. Distinction is troublesome: it has more pains than pleasures; it is jealous, envious, and distrustful. Power does not make one happy; it demands the most busy watchfulness to keep it. If lost, its absence is often followed by painful suffering, and the possession of it is always accompanied with the fear of losing it. Riches are sometimes regarded as means of enabling

one to live in elegant luxury, and even in voluptuous enjoyment. This is no way to be happy; the appetites soon become satiated; the stomach wears out; the senses are palled; diseases come: the body may be racked on a velvet couch as well as on a straw bed. Is there, then, any such thing as happiness? There must be such a thing, or the laws of nature, which provide for physical, intellectual, and moral being, are false and deceitful, and the gift of revelation is a fable. If there be such a thing as happiness, it will be found in that knowledge of and obedience to the laws of nature which make health. It will be found in obeying the propensity to action, to some continuous, useful end; that is, in pursuing reasonably some one of the many vocations in society which tend to secure one's own self-respect and peace of mind, and which tend also to the common good. But there may be disappointments, ill luck, and causes of mortification and sorrow. These, we apprehend, do not seriously disturb any well-regulated mind, when there is a consciousness that no reasonable foresight or prudence would have discerned and prevented the cause. Perfect happiness in this world, it must ever be remembered, is not to be expected: the only happiness that we can really attain consists in a certain contented tranquillity of mind under all the shocks and changes of this mortal life. There is a point called the *happy medium*; and this should be an aim in all human arrangements. Be moderate in all things. For example, to take no amusement is bad, for it deprives the mind of needful rest and recreation; so likewise it is bad to be altogether given up to amusement, for then all serious objects are lost sight of. The true plan is to take amusement in moderation. Some minds have never awakened to a taste for poetry, fiction, the imitative arts, and music, and they thus lose much pleasure which others enjoy: again, there are some in whom nature has implanted, and use cultivated, so strong a predilection for these things, that it becomes a vice. To be very much in society is sure to deteriorate the human character, making it frivolous, and incapacitating it for taking abstract and elevated views: on the other hand, a perfectly solitary life weakens the mind, lays it open to odd fancies and eccentricities, if not to hypochondria, and ends in some instances by altogether throwing it from its balance. The medium is here also found alone salutary. To be excessively gay, in a world where so many evils lurk around our every step, and so many onerous things call for our attention, is wrong: so is it to be always serious, seeing that the world also contains the materials of much happiness. What is proper is, that we should be ready to rejoice and mourn in moderation on the appropriate occasions. Finally, one may feel assured, that if he abide by these moderate desires, and so use his time as to be reasonably busy to some good purpose, and so conduct himself as to be justly entitled to his own approbation, and if he live in the habitual assurance that there is an omnipresent, omniscient, and merciful Judge of moral, accountable, and immortal man, he will certainly be happy.

NOTE.—The matter of this sheet has been extracted, with a few slight alterations, from the Moral Class-Book of Mr William Sullivan, published a few years ago at Boston, in the United States. Of the excellence of purpose, firmness and expressiveness of language, profound observation, and amiable sentiment, displayed in this book, we need hardly speak, after presenting the reader with such ample materials for forming a judgment of his own. It is impossible, however, to omit the opportunity of congratulating our brethren on both sides of the Atlantic—for we never can consider them but as one nation—on the rise, in America, of a body of moral writers, of whom Mr Sullivan is but a specimen, who seem resolved, as they are unquestionably able, to seek the improvement of their fellow-creatures in all that tends to elevate them in the scale of being. The present sheet contains Mr Sullivan's view of the Duties which one owes to Himself: another, which follows, will comprehend the Duties which one owes to Others, as classified in the opening paragraph.

PUBLIC AND SOCIAL DUTIES OF LIFE.

THE preceding article upon this subject embraced the duties which one owes to himself as a rational being. The present is not less important in its character, being intended to point out those duties which we are required to perform with respect to our various public and domestic relations. We begin with our

DUTIES AS SUBJECTS.

Every civilised nation is governed by some species of authority, for the purpose of preserving order in society. Some governments are good, others are bad; but it does not fall within our province to point out where the ruling authority is injurious, or where it is most advantageous to the people. According to a law of universal application, every independent nation is understood to have the undoubted right to model its government according to its own fancy, genius, or necessities, provided that, in the execution of its plans, it does not wantonly injure its neighbours. Directing our attention to our own country, with which we have here alone to do, we find, as soon as reason dawns upon us in youth, that we are members of a great and enlightened community. We find ourselves subject to laws which were framed long before we were born, and that we must act in a manner not to please our own caprice, but according to the arrangements which have been instituted for the benefit of society at large. But if we thus discover that we are trammelled by certain legal restrictions, not very agreeable perhaps to the wildness of our untamed nature, we likewise find that we possess a great many compensating privileges. While yet opening our eyes to the light, we enter into the enjoyment of all the transcendent privileges of British subjects, and come within the powerful protection of the laws as fully as the oldest and most honoured in the land. It will be perceived that this is a boon of incalculable value. For us, armies have fought and bled; for us, in past time, hosts of martyrs and patriots have contended; for us, the wisest statesmen and legislators have transacted negotiations securing civil liberty; for us, the people who have gone before us have established a variety of the most excellent, the most beneficent, institutions. All these things we enjoy without having been put to the smallest trouble. All that we are called on to give in return, as soon as emancipated from the ignorance of childhood, is *obedience to the laws*.

A cheerful obedience to the laws is, therefore, our chief public duty. Possibly some of our laws, from having been framed for a former state of society, or in order to meet particular exigencies, may not now be very judicious in their provisions; yet that forms no solid reason why we should break through them. It is always safer to obey a bad law than to oppose it by violence. Unhappily for some nations, they seem to have no accurate idea of the value of obedience to the laws. When they find

themselves aggrieved by oppressive state measures, they are exceedingly apt to break into tumults, and take up arms against the officers of their governments. This is a very shortsighted policy, as the history of all nations proves; for the people are always sure to suffer far more by the coercive measures adopted to restrain them than they would have done by submitting to the evil they originally complained of. It is the boast and glory of Britain—and long may it be so—that its people know how to respect the laws, even while they consider them to be injurious, and how to correct them by quiet and orderly procedure. In this lies the important secret of their national greatness, their wealth, their public liberty. The advantages arising out of a scrupulous obedience to the laws, consist, in the first place, of social order and quietude, by which the rights of property are respected, commerce and trade permitted to flourish, and the sacred inviolability of the person preserved. The results of turbulence and civil commotion are, poverty, ruin to property, insecurity of the person, destruction of commerce and trade, and at length, military oppression and barbarism. Every intelligent man, therefore, in this country, yields not only a bare submission but a becoming respect to the laws, as well as to the various institutions established by their authority.

Perfect obedience both to the letter and the spirit of the laws, does not, however, imply that we should not examine whether they are in every respect answerable to the present condition of society, nor keep us from resorting to legal means to have them corrected, or altogether rescinded. The constitution points out how this is to be done. It is illegal to conspire secretly to overthrow the law. All measures calculated to improve our social condition must be conducted openly and honourably. The means put into our hands by the constitution for improving the law are very powerful, if wielded with discretion. The people have the appointment of the men who constitute the most influential branch of the legislature; if they do not appoint individuals who will meet their views with regard to correcting or abolishing laws, they have themselves to blame: the constitution confers upon them a liberty of choice. It besides gives them the right to present petitions to the legislature, either individually or in bodies, praying in respectful terms for the amendment or abolition of any law which is deemed oppressive or antiquated. This right gives a vast addition to the power of the people. It is of much greater value than one would at first be inclined to suppose, and is infinitely preferable to the use of violence. The right of petition implies the right of meeting publicly to discuss the propriety of petitioning. This practice of meeting together excites the public mind to renewed efforts in the cause it undertakes. The speeches of the orators are circulated and commented upon by the newspapers all over the country. One meeting gives rise to others,

men's minds are enlightened and warmed, and the public opinion acquires a degree of moral force, any resistance to which would be useless. It is not without reason, therefore, that the people of this country set so high a value on the right to assemble for the discussion of public affairs, and place it in the first rank of their constitutional prerogatives.

Besides yielding obedience to the existing laws, we are under a collateral obligation to be loyal to the sovereign who rules over us. Loyalty is hence another of our chief public duties. There is some difference of opinion with regard to what extent loyalty ought to be carried. It appears to us that this is a simple matter. A power to protect the nation from foreign insult, and to preserve the internal peace of the country, *must be lodged somewhere*. It is found to be most convenient to lodge it in the hands of one person, under proper restrictions. In Great Britain, as will be seen in our history of that country, it has been placed in the possession of a hereditary prince or king. This person is entitled our ruler or sovereign; we are termed his subjects. Loyalty signifies a fidelity and willingness in serving the king, so that he may be enabled both to protect the nation from outward harm, and to preserve order in society, through the agency of the laws, or, failing them, through the application of force. Seeing that the sovereign is prevented by the constitution from infringing upon the rights of the subject, through the exercise of his power, it is discovered that loyalty is rewarded in the comfort we enjoy; or, to use another expression, self-interest alone, if no nobler sentiment interfere, would lead us to afford assistance to the king in the execution of his high and important trust. This assistance is demonstrated, not only by personal service, if necessary, but by respect. Loyalty may be greatly enhanced by esteem for the private virtues and conduct of the sovereign. When so influenced, it is certainly both an amiable and commendable feeling, and can never, but in ill-regulated minds, degenerate into servile prostration.

In the United States of America, in which the executive is lodged in an elective president, the people call themselves citizens, not subjects; and what we mean by loyalty to the sovereign, they term duty to the commonwealth. It is obvious that there is extremely little essential difference, *practically*, between these phrases, whatever there may be in *feeling*. The subjects of Great Britain are as free as any people in the civilised world; much freer, indeed, than the inhabitants of France, who disclaim the appellation of *subjects*. These explanations are perhaps useful in admonishing us to beware how we vex ourselves about mere words and sounds. Our duty clearly consists in appreciating the numerous blessings we enjoy in our public and private relations, by whatever name these relations may be called. We are each individually fractional parts of a great nation, whose honour we are called on to sustain through good and bad report. Let us remember that individual virtue can alone promote social happiness, and that social happiness and peace form the basis of political independence. No man can be a good and respectable subject or citizen who is a bad son, a bad husband, a bad father, or a bad master. The nation is but a composition of a great many families, knit together by kindred sentiments and mutual wants; and how can it be great, or worthy of esteem, if its component parts exhibit in their constitution the worst of vices?

Loyalty to the sovereign leads to a subordinate but important duty. It induces us to respect inferior constituted authorities. All judges, magistrates, or other civil functionaries, stand in the light of representatives of the sovereign. The king cannot be every where at once, and he deposes these individuals to attend to the wants of his subjects, and to keep good order in society. To show contempt for any court of justice, or for any magistrate, is, therefore, equivalent to showing contempt for the king himself, as well as for the laws, and is justly punishable. To show our respect both for the laws and the sovereign, we must respect the decisions of judges

and magistrates, and support their due execution by our personal influence. Nevertheless, it is in every one's power, when they feel themselves aggrieved by these decisions, to appeal to higher authorities for redress; such being the only means allowable by the constitution, in opposing the legal power of the established courts of civil and criminal jurisprudence.

A becoming obedience to the laws, and a generous respect for the supreme and inferior constituted authorities, produces the agreeable result of good order and peace in society. Every one is not acquainted with the different ramifications of the common and statute law; indeed it would be impossible for us to acquire a correct knowledge of these things unless we devoted a lifetime to the study. This difficulty in acquiring a knowledge of the laws, has sometimes given rise to a low sort of jeering at our excellent constitution, and it has been represented as cruel to compel an obedience to laws which few can have an opportunity of learning. But this is a fallacy into which we hope our young readers will not fall. The administration of the common law, such as that which applies to inheritance, debtor and creditor, and civil rights generally, rests with a body of educated men, or lawyers, whose services may at all times be commanded. Besides, we may, if we please, purchase digests of these laws for our private amusement and instruction. The other description of law which is made applicable to the preservation of the peace of society, any one can understand, if he have the ability to know right from wrong. We surely all know that it is illegal and criminal to steal, to rob, to murder, to break into our neighbours' houses, or to attack their persons by violence. It can require no reading of acts of Parliament to understand this. Common sense here serves us instead of legal knowledge.* Our duty in this matter is very easily defined. We must ever bear in mind that one of the principal acts of duty which the constitution enforces, is the abstaining from meddling violently with the persons and property of our fellow-subjects. In this well-regulated realm, the person of every man, woman, and child, is inviolable from private attack. It is a crime almost punishable with the highest penalty of the law, to strike any one, either from an idea that they have injured us, or through the influence of passion and prejudice. If we consider that we have been injured, we must apply to the law or the magisterial authorities for redress. We are only permitted to use physical force when in absolute danger of losing our lives or property by violence, there being then no time to apply to the law for protection. It would be gratifying if these regulations were more generally attended to than they seem to be. There are many young men, who, from what they are pleased to term a love of fun, but which can be no other sentiment than a love of mischief, or gross ignorance, assail the persons of individuals of both sexes, to their great discomfort, and sometimes serious injury. Now, it is clearly illegal to do so, and is generally punished by the infliction of severe penalties by the civil magistrate, though seldom marked with that ignominy which it deserves. Inasmuch as it is held that ignorance of the law does not excuse its infraction, so is it reckoned an invalid apology for the commission of crime to say that you were under the influence of intoxication at the time. Drunkenness is very properly esteemed an aggravation, not a palliation, of the offence.

CONDUCT AT PUBLIC MEETINGS.

The right of meeting together publicly to discuss matters connected with our social condition, being so invaluable a prerogative, it is right and fitting that all young men entering into the busy scenes of life should make themselves well acquainted with the rules which

* At the same time, we willingly allow that there is room for great improvement in the dissemination of a knowledge of the statute law, particularly that of a recent date. It is likely that some plan will soon be carried into execution to remedy this defect.

have been established by general consent for the proper conducting of such assemblages.

According to usage, a public meeting is not constituted until a person be appointed to preside, or to "take the chair." Without this ceremony, the meeting is a tumultuary assembly, or a mob. The first movement is, therefore, the appointment of a chairman. This functionary, on taking his seat, is for the time supreme in the meeting. His chief duty is the preservation of order. He allows only one to speak at a time, giving the preference to him who has first caught his eye in the act of rising, and giving every speaker a fair hearing. Another of his chief duties is the preventing of speakers from wandering from the subject under discussion; and if they do, he must remind them to keep to the point. In the execution of these and other duties, he claims the support of the meeting, and all are bound to yield to his reasonable dictates, and help to maintain his authority. In proportion to the firmness, yet mildness of manner, of the chairman, so is the meeting well or ill conducted.

At some public meetings there is no set plan of operations, and a general discussion on the subjects which are brought forward takes place; but at all meetings for specific important objects, there is a previous arrangement among a certain number of individuals to bring forward particular points to be spoken upon. In this case speakers are prepared, and the business assumes the form of the proposal and carrying of a set of resolutions, or motions. The following is the routine of procedure:—The chairman having stated the object for which the meeting has been called, an individual steps forward and proposes a resolution for the adoption of the meeting. Whether he enforces the propriety of carrying such a resolution by a speech on its merits, or simply propounds the matter, he must be *seconded* by another individual (with or without a speech), otherwise the meeting cannot entertain his resolution for a moment. If duly seconded, then the motion is fairly tabled. It is before the meeting. After a resolution is proposed and seconded, it is the duty of the chairman to ask the meeting if it be carried or not; if agreed to by a general acclamation, or by an obvious majority, he pronounces the word "carried," which settles the point, and the business proceeds by the bringing forward of the other resolutions in the same manner. It is unusual for any member of a meeting to oppose the passing of a resolution, unless he have a better to offer in its stead. If he have, and if he wishes "to take the sense of the meeting" on the subject, he has a right to be heard. Yet this can only be permitted, provided the meeting has been called in general terms. For instance, if the inhabitants of a town or district generally be called, in order to *consider* of the propriety of such and such measures, in that case every one is entitled to give his opinion, and to oppose the formal resolutions brought forward. But if the meeting be described by advertisement to consist of those inhabitants or others only who agree in the propriety of such and such measures, then no one is entitled to intrude himself on the deliberations who professes opinions contrary to the spirit and end of the meeting. An inattention to this exceedingly delicate point often creates serious heart-burnings and disturbances; and, on that account, committees who call public meetings ought to be very particular in the terms of their announcements.

As much regularity is necessary in respect of opposition to motions as in their proposal and carrying. The counter-motion of an opponent is called an amendment, which, to be available, must also be seconded. If not seconded, it drops; but the opposer may place his protest on record; that is to say, if the discussion be in a corporation, or other meeting where books of the minutes or transactions are kept. On being seconded, and discussed by those who wish to speak upon the subject, the matter is brought to the vote by the chairman, but not until both the mover and amender have replied, if they please to do so. After they have spoken, not another word can be uttered, and the vote is taken,

a majority carrying. If the votes be equal in number, the casting-vote of the chairman carries. There is another way of suppressing a resolution, which is by "moving the previous question." This signifies, to return to the point at which the business of the meeting stood previous to the tabling of the motion; or means, in other words, to do nothing on the subject. But this must also be seconded, and put to the vote in opposition either to the motion or amendment, or to both. The routine is generally to place it in opposition to both; if carried, the matter is settled; if not carried, the order is next to place the motion and amendment against each other, and vote.

Such is an outline of the mode of procedure at public meetings, and it is particularly desirable that attention should be shown to the preservation of regularity. At all public meetings there is a strong tendency "to go out of order." By this expression it is meant that speakers are under a constant liability to wander from the point under discussion. They are apt to digress into other subjects, and confuse their auditors; and these, getting impatient, are equally apt to interrupt them, so that a single irrelevant observation may lead to hours of idle debate or colloquy, or "speaking to order," as it is termed, and thus the harmony of the assembly be destroyed. Those who attend such meetings should therefore have a regard for the following regulations:—If they speak, they should keep closely to the subject in hand. If they be listeners, they should preserve a strict silence. It is ungentlemanly, not to say disorderly, to utter any sound or make any observation on what a speaker is saying. The speaker must on no account be interrupted, so long as he keeps to order; and if not in order, it is the chairman's duty to check him. It is likewise disorderly to speak more than once, except in replying before the vote is put, or except it be the rule of the assembly to permit it. Sometimes persons who have spoken rise again to speak as to "a matter of form." This is allowable, but in speaking as to form, the merits of the case should not be introduced. On this, however, as on every other point, there is a perpetual tendency to go out of order, and hence the absolute necessity for appointing a chairman well acquainted with the forms of public deliberation, and who has the strength of mind to insist on order being preserved.

At all our public assemblages, a certain degree of courtesy is used both among speakers and listeners. On an individual rising to speak, he addresses himself politely to the chairman, and the chairman in return politely mentions the name of the speaker; by which means the audience is made acquainted with the gentleman who is about to address them. When the discussions of the meeting are over, the chairman closes the business with a few observations, and then dissolves the assembly by leaving the chair. When any dispute arises in the course of the business of the meeting upon points of form, it is customary to appeal to the usages of the House of Commons for an example to be followed.

DUTIES AS ELECTORS.

There are duties of another nature which we may be called on to perform in our character of citizens. We are invested with the high and solemn trust of electing our representatives in Parliament, as well as representatives in our municipal institutions. In the execution of our duty as electors, we are bound to divest ourselves of all factious or personal considerations. We have certainly to consult our own good in making a choice of a representative, but it is only as flowing from the good of the whole community. We must hence act entirely without passion or prejudice. Let us examine the previous habits of life, public conduct, and avowed sentiments, of candidates, and calmly consider whether they are such as we can approve of, or as being consistent with the general welfare of the people. We should also recollect that we exercise the trust of electors for many who do not possess that privilege. A large proportion of the community consists of women

and children, persons in an humble condition, the sick, and the helpless. These look to us for protection from wrong, and it is our duty to afford it to them. If we, therefore, act with levity and imprudence in appointing men, who, from their conduct and character, are unfitted to exercise the important function of public representatives, we in more ways than one commit a crime against society, and are unworthy of possessing the valuable prerogatives with which the constitution has invested us.

In our capacity as citizens, we are frequently called upon to elect representatives in different municipal bodies; such as civic managers of the city in which we reside, managers of local trusts—general, political, and religious. There is often much heat at such elections; a petty factious spirit frequently governs the choice which is made: sometimes the meanest passions of our nature are exhibited during the contest. The observations we have made on our duties as electors generally, apply here with peculiar force. As those who present themselves as candidates live amongst us, we can never find any difficulty in estimating their character and qualifications. But we must take care not to be borne away by private feelings; we must not give our vote simply because the candidate is an acquaintance. A consideration for *what is best for the public interest* should in every case govern us; and we should not be afraid to let these our sentiments be known, for they can give no honourable man offence. In all cases of elections of members of civic corporations, and such like bodies, the chief merit in electors, after that of good and respectable character, is soundness of judgment, and after that, activity of habits. The power of fine speaking, or eloquence, is not required in such a functionary, and should be esteemed very lightly. That which is required is a power of thinking coolly, an integrity of purpose, and a willingness and ability in taking a share of the burdensome duties to be performed. Our qualifications as electors, perhaps, render us liable to be ourselves elected. In the event, therefore, of being called forward by our fellow-citizens to fill the honourable situation of their representative, it is our duty to sacrifice perhaps our own feelings and a portion of our time in the public service, provided we conscientiously consider ourselves qualified for the task, and that our health and private circumstances permit it. The principal question we have to put to ourselves, when we are so brought forward, is, "Have we sufficient time to spare to attend the various meetings—to sit and deliberate in the numerous committees—to have our minds frequently occupied with public affairs?" If we deceive ourselves in answering this important question, we wrong society, and give ourselves cause for much after disquietude. Is it, or not, the proper way for every one who is worthy of this trust, calmly, deliberately, and to the best of his knowledge and belief, to do those acts which will best preserve for his own use the beautiful fabric of our political institutions? If he perceives and rejoices in the good which he and others derive from it, will he not best perform his duties to those who come after him, to use it, and not abuse it, that they may have the like good? Little suggestions of selfishness, rivalry, and petty local interests, and, most of all, perverted and mischievous ambition, are the blocks over which citizens stumble and fall, in the otherwise luminous and clear path in which they are permitted to move.

DUTIES AS JURORS.

The laws under which we live give us the invaluable privilege of trial by jury; in other words, we are tried for the commission of offences by a body of men chosen indiscriminately, as nearly as convenient, from the class of society in which we have moved. By such a considerate regulation, there can be little risk of individual oppression, provided those who compose juries do their duty. It is therefore incumbent on citizens who are liable to serve in juries, to make themselves acquainted with what is understood to be their duty when so called

upon. It requires no learning to fulfil the character of a juror. It requires no more than a coolness of thinking, and a mind above being carried away by prejudices or feelings. The juror is to remember that it is the jury which is the judge in the case, not the judges who sit on the bench. Keeping this in view, it is one of the chief qualities requisite in a jury to maintain its proper dignity and honour inviolate, nevertheless with all courtesy, and to act with firmness in the execution of its important function. Besides deliberating dispassionately on the evidence presented, it is the duty of the juror to be totally regardless of every consideration but that of strict justice. He is neither to regard the rank of life of the culprit, nor of the injured party. In a court of jurisprudence all men sink to an equality. It is also the duty of the juror, after forming his conscientious opinion, not to be coerced, or flattered, or spoken into a different opinion. He is invested with a solemn trust, and that trust he must preserve with scrupulous care, as consonant with the dearest interests of society.

DUTIES AS NEIGHBOURS.

Besides the duties which we have to perform as members of a great nation, we have duties of a similar nature to perform as inhabitants of a town, district, or neighbourhood, and in relation to which we sometimes receive the appellation of citizens. Every person belongs to a neighbourhood, which is both local and social. Even those who have removed into new countries, and who dwell in solitary abodes, do not lose the sentiment of neighbourhood. The nearest person to them is a neighbour, though separated by long distance. And when this sentiment cannot be preserved in fact, it may be in thought, and by that means it usually is so. Perhaps the last impressions that leave the heart of one who has wandered into far distant regions, are those made in his early days, in his native home. In general, as every one lives in a neighbourhood more or less dense, he can promote his own happiness, and that of those around him, by observing a becoming moral conduct. He has a right to enjoy life, and to use all things which he has, to that end; but he has not a right to any enjoyment which necessarily disturbs that of others. Peace, tranquillity, and security within one's own walls, is the main purpose of life. No one has a right to interfere in these things but by order of the public law. A neighbour, therefore, who so conducts himself, and those means of pleasure which he commands, as to vex, harass, and disturb those who are necessarily within sight, hearing, &c., commits an offence against morality. It often happens to be the pleasure of one who dwells in a dense neighbourhood, to keep one or more animals, whose habitual noises disturb those who necessarily dwell within hearing, in the hours allotted to repose, and frequently when persons are visited by sickness, and when any noise is distressing. Now, whatever the rigid law of the land may say in such cases, the law of morality says that the suffering party has an unquestionable right to remove his trouble, if the proprietor of the cause of such nuisance will not, on request, remove it himself. A more peaceable way would be, to have it removed by order of the public magistrate. Many of such petty nuisances ought to be removable on summary verbal application, and not in the slow, written, and printed process, in which the movements of ordinary law are commonly made.

The moral duties of neighbourhood extend to all things which minister to the common comfort, convenience, and security. Each one of a neighbourhood is bound to make his own dwelling-place as agreeable and pleasant to those around him as he reasonably can. Each one is morally held to uphold and sustain a good name for his own little community. He is, therefore, to join, with a liberal and manly feeling, in all the improvements which tend to please and adorn. Such things, even if they occasion some expenditure, are sources of self-satisfaction; and one comes at last to take

an honourable pride in hearing his street, his village, his town, or city, commended by observers.

There is another sort of neighbourhood which is founded in social intercourse, and in the interchange of visiting and hospitality. As the world now is, this is commonly regulated by artificial and somewhat unnatural rules. It is often ostentatious, luxurious, and destitute of all feelings and thoughts in which well-trained moral minds can take pleasure. A profuse and voluptuous entertainment, comprising food little adapted to promote health and vigour, and in quantity sufficient for ten times the number, that rather look at than consume it, is an unsatisfying way of being happy in social intercourse. There are modes of maintaining such intercourse, which are innocent, pleasing, and dutiful. Mankind are fitted for such. The interchange of friendly visits, for conversation, music, and rational amusement, with such things as may be used without suffering or impairing health, is that kind of neighbourhood (in such relations) which is permitted and enjoined. We have, however, little reason to think that intimacies of this sort are likely to meet with such consideration as would induce the further extension of them.

Every person, in general, is a member of some kind of society or association. Some persons belong to many. These are intended for some useful purpose. Every one who is such member has some duties to perform. He owes some proper part of his time, some proper contributions, to the common object, and has an interest in the prosperity of the design. All these institutions do some good, and some of them eminent good, in helping on the great purpose of social life, which is general improvement. Of this nature are public charities, educational institutions, libraries, agricultural societies, and those for suppressing intemperance and immorality. No well-disposed citizen can conscientiously abstain from giving his aid and support to such objects. It is each one's duty to try to leave the world a little better than he found it. No one can say these are matters which do not concern him. Suppose every one should say so, and had said so from the beginning, society would still be made up of barbarians. Every good that is done in any community affects, directly or indirectly, every member of it. The law of example, of imitation, of doing as others do, has a most pervading and astonishing influence. Every community is like a full vessel of water; no one drop in it can be moved without affecting every other drop.

DUTIES IN OUR DOMESTIC RELATIONS.

Marriage.—This institution is agreeable to a law of nature, and is an ordinance of the Creator. There are profligates who have doubted this; but they have exhibited no reason on their side. It is obvious that man is not only a gregarious, but a pairing animal. Marriage is consistent with the finest of his feelings—the most noble of his faculties. It began when man began. It is ordered to perpetuate the succession of the human family. It is ordered for the whole duration of adult age. It is man's peculiar privilege in this; it connects him with generations which are gone, with that which is passing away, and with those which are to come. The memory and the ashes of the dead are precious to him, and no other animal has that sentiment. He alone contemplates that his own memory will be held in honour, and that the place of his earthly quiet will be sacred. He only is enabled to conceive that moral and physical wrong will bear his own stamp in the character and in the frame of those that follow him; he only knows that a good name may be an honourable inheritance. These are the sentiments which spring from the beneficent gift of marriage. However much one may misunderstand or abuse this gift, nature, ever faithful to her trust, forces these sentiments on the heart.

Marriage is recognised as a contract of a binding nature in all civilised nations. By some it is considered, from its solemnity, to be of a sacred character; by others it is deemed only a civil bond of connexion. All, however, agree in holding it to be an irrevocable con-

tract. The laws of the land, those of nature, and the divine law, disclose the sentiments, the feelings, and the awful sense of duty with which this undertaking should be regarded. Yet it is frequently entered into from motives highly reprehensible, and sometimes with shocking thoughtlessness. It is from such causes that we see that this sacred union, which should be the true source of the highest human happiness, becomes that inexhaustible fountain from which both parties are daily and hourly compelled to drink, and from the same cup, the bitterest waters.

In a great number of instances, marriage is contracted with exceedingly little regard to the qualities of the mind on either side, particularly on the side of the man. If one could penetrate the ear of an enamoured youth, some good might come from such suggestions as these:—Do you know what will come of that engagement which you are about to make? Are you about to tie yourself by bands, absolutely indissoluble while you live, to a mortal who has feelings, wishes, wants, hopes, and fears, which must become yours, and a part of your very self; or which you must resist, control, or contend with? Do you know that pain, suffering, and sorrow, originating in either, must be borne by both? Are you aware that whatsoever of error, folly, or crime, may be chargeable to either of you, or to any who may spring from your contract, will be your common burden and shame; and that from these you can relieve yourself nowhere but in the grave? Or, do you know that this attractive being will be your kind friend; your counsellor; the welcome soother of your cares and anxieties; the generous and charitable judge of your infirmities; the inspirer of honourable ambition; your fellow-labourer in joint interests; the ornament of your life; the gracious, considerate, faithful, gentle companion, who will make your own virtuous home the place to which you refer all earthly happiness? Who that is "in love" has leisure or inclination to think of such trifles as these?

There is no reason why the passion of love should be wrapped up in mystery, nor any why the mind should be stained in considering its nature. It would prevent much and complicated misery in the world, if all young persons understood it truly. There are in every human being seeds, each one of which may be made to germinate, and may be so cultivated as to produce the most odious vices or the most serene and heavenly virtues. There is in every human heart a fund of kindness, tenderness, and affection, which makes itself known to be there in due time. It demands to be applied. This is the trying and perilous moment in youthful life. There is some one, some where, who will take that fund, and give back its full equivalent. The external senses and the heart are in search of that one. Happy will it be for the searcher, if he will take reason as a monitor to keep the senses and heart in order. But reason is commonly regarded, not as a kind and faithful friend, whose duty it is to whisper, "begin nothing of which you have not well considered the end," but as a withered scowling matron, who, being utterly dead to the impulses of youth, denies that there ought to be any. If there has been no preparation for this eventful period; if the mind has not been enriched with the teachings of rational prudence; if the eye has not been taught to distinguish between the real and the fictitious; if the ear has not learned to discriminate the meaning of sounds; if life as a whole, if the consequences of irrevocable deeds be not thought of, there is peril; and the pure drop from the fountain may flow into any sea but that of happiness. In seeking for that being who is to be a companion during life, one grievous failing must be avoided. Young men frequently amuse themselves by playing with the feelings of young women. They visit them often, they walk with them, they pay them divers attentions, and after giving them an idea that they are attached to them, they either leave them, or, what is worse, never come to an explanation of their sentiments. This is to act the character of a *dangler*, a character truly infamous.

Young men cannot be too cautious in the attentions which they bestow on unmarried females, who on their part should be equally guarded in not encouraging the addresses of any individuals whom they would not choose to marry.

According to the present state of society, one of the influential counteracting elements to marriage is, or ought to be, a high degree of prudence. No one ought to marry who cannot foresee that he will be able to support the additional expenses of a wife and family, and at the same time fulfil his other necessary obligations. By good management, these additional charges are not great, but they amount to something, and he is worse than an infidel who does not provide against them. We are of belief that every industrious, active, and sober man, will find no serious obstacle in this respect. It is from idleness, love of company, and intemperance, not from simple expenditure on family necessities and comforts, that ruin and poverty in the married life are produced. The dread of encountering the expenses of a family, though acting as a salutary check on imprudent marriages, is frequently productive of many gross vices, tending to the injury both of individuals and of society. Celibacy, especially when circumstances would permit marriage, is not respectable; it is considered akin to vagrancy. He who marries and settles down as a householder, meets with the approbation of the world. Why is this? it may be asked. Because in marrying we give a guarantee to society for our good behaviour. It is not to be doubted that a young, well-educated, industrious couple, who are sincerely and affectionately attached, on a sober examination and conviction of each other's worth and suitability to each other, may be happy with means far short of the fashionable standard. Presuming that such a couple are wise enough to take life for the real and substantial good that it can produce—and as a whole, it would do them great injustice to suppose that they could not find that good in a small, simple, cheerful, tranquil mansion—it would be doing the friends of such a couple the like injustice to suppose that they could not visit them, and be satisfied to see them happy through such means.

According to the usages of society, it is the custom for the man to propose marriage, and for the female to refuse or accept the offer as she may think fit. There ought to be a perfect freedom of the will in both parties. To impose any species of constraint on either party is most mischievous; it would be a gross violation of our most sacred privileges. Both parties, therefore, ought freely to think for themselves, however much they may seek the advice of those who are inclined to afford them counsel.

In treating of this subject, it may be of service to offer a few special advices to young women. Our first recommendation is, that they ought to be in no haste to accept a lover. Let them know him a sufficient time to judge of his qualities of mind, temper, habits, &c., before they allow themselves to be inveigled into a marriage with him. Far better for them to remain single, than heedlessly incur the risk of being miserable during the remainder of their lives. In general, young women are much too anxious to involve themselves in this respect. The following observations on the injurious effects of making marriage the sole object of a young woman's thoughts, occur in a popular work by Mrs Farrar, and are well worth attention.

"Some one has said, that 'matrimony is with women the great business of life, whereas with men it is only an incident'—an important one, to be sure, but only one among many to which their attention is directed, and often kept entirely out of view during several years of their early life. Now, this difference gives the other sex a great advantage over you; and the best way to equalise your lot, and become as wise as they are, is to think as little about it as they do.

The less your mind dwells upon lovers and matrimony, the more agreeable and profitable will be your intercourse with gentlemen. If you regard men as intellectual beings, who have access to certain sources

of knowledge of which you are deprived, and seek to derive all the benefit you can from their peculiar attainments and experience—if you talk to them as one rational being should with another, and never remind them that you are candidates for matrimony—you will enjoy far more than you can by regarding them under that one aspect of possible future admirers and lovers. When that is the ruling and absorbing thought, you have not the proper use of your faculties; your manners are constrained and awkward, you are easily embarrassed, and made to say what is ill-judged, silly, and out of place; and you defeat your own views by appearing to a great disadvantage.

However secret you may be in these speculations, if you are continually thinking of them, and attaching undue importance to the acquaintance of gentlemen, it will most certainly show itself in your manners and conversation, and will betray a weakness that is held in especial contempt by the stronger sex.

Since the customs of society have awarded to man the privilege of making the first advance towards matrimony, it is the safest and happiest way for woman to leave the matter entirely in his hands. She should be so educated as to consider that the great end of existence—preparation for eternity—may be equally attained in married or single life, and that no union but the most perfect one is at all desirable. Matrimony should be considered as an incident in life, which, if it come at all, must come without any contrivance of yours; and therefore you may safely put aside all thoughts of it till some one forces the subject upon your notice by professions of a particular interest in you.

Lively, ingenuous, conversable, and charming little girls, are often spoiled into dull, bashful, silent young ladies, and all because their heads are full of nonsense about beaux and lovers. They have a thousand thoughts and feelings which they would be ashamed to confess, though not ashamed to entertain; and their preoccupation with a subject which they had better let entirely alone, prevents their being the agreeable and rational companions of the gentlemen of their acquaintance which they were designed to be.

Girls get into all sorts of scrapes by this undue preoccupation of mind; they misconstrue the commonest attentions into marks of particular regard, and thus nourish a fancy for a person who has never once thought of them but as an agreeable acquaintance. They lose the enjoyment of a party, if certain beaux are not there whom they expected to meet; they become jealous of their best friends, if the beaux are there, and do not talk to them as much as they wish; every trifle is magnified into something of importance—a fruitful source of misery—and things of real importance are neglected for chimeras. And all this gratuitous pains-taking defeats its own ends! The labour is all in vain; such girls are not the most popular; and those who seem never to have thought about matrimony at all, are sought and preferred before them." We may add the advice, that young women should not consider it a serious misfortune even if never married: there is nothing disreputable, while there may be much happiness, in the condition of an old maid.

HUSBAND AND WIFE.

Marriage having at length taken place between two parties who feel a reasonable hope of being happy together for life, each has entered on a condition requiring the exercise of particular duties. These we shall endeavour to narrate, commencing with advices

To Husbands.—"I. Always regard your wife as your equal; treat her with kindness, respect, and attention; and never address her with the appearance of an air of authority, as if she were, as some misguided husbands appear to regard their wives, a mere housekeeper.

II. Never interfere in her domestic concerns, such as hiring servants, &c.

III. Always keep her properly supplied with money for furnishing your table in a style proportioned to

your means, and for the purchase of dress, and whatever other articles she may require, suitable to her station in life.

IV. Cheerfully and promptly comply with all her reasonable requests.

V. Never be so unjust as to lose your temper toward her, in consequence of indifferent cookery, or irregularity in the hours of meals, or any other mismanagement caused by her servants; knowing the difficulty of making many of them do their duty.

VI. If she have prudence and good sense, consult her in all great operations involving the risk of very serious injury in case of failure. Many a man has been rescued from ruin by the wise counsels of his wife; and many a foolish husband has most seriously injured himself and family by the rejection of the advice of his wife, stupidly fearing, if he followed it, he would be regarded as henpecked! A husband can never consult a counsellor more deeply interested in his welfare than his wife.

VII. If distressed or embarrassed in your circumstances, communicate your situation to her with candour, that she may bear your difficulties in mind in her expenditures. Women sometimes, believing their husbands' circumstances better than they really are, disburse money which cannot be well afforded, and which, if they knew the real situation of their husbands' affairs, they would shrink from expending.

VIII. Never on any account chide or rebuke your wife in company, should she make any mistake in history, geography, grammar, or, indeed, on any other subject. There are, I am persuaded, many wives of such keen feelings and high spirits (and such wives deserve to be treated with the utmost delicacy), that they would rather receive a severe and bitter scolding in private, than a rebuke in company, calculated to display ignorance or folly, or to impair them in their own opinion, or in that of others.

To Wives.—I. Always receive your husband with smiles—leaving nothing undone to render home agreeable—and gratefully reciprocate his kindness and attention.

II. Study to gratify his inclinations, in regard to food and cookery; in the management of the family; in your dress, manners, and deportment.

III. Never attempt to rule, or appear to rule, your husband. Such conduct degrades husbands—and wives always partake largely in the degradation of their husbands.

IV. In everything reasonable comply with his wishes with cheerfulness—and even, as far as possible, anticipate them.

V. Avoid all altercations or arguments leading to ill humour—and more especially before company. Few things are more disgusting than the altercations of the married, when in the company of friends or strangers.

VI. Never attempt to interfere in his business, unless he ask your advice or counsel; and never attempt to control him in the management of it.

VII. Never confide to gossips any of the failings or imperfections of your husband, nor any of those little differences that occasionally arise in the married state. If you do, you may rest assured that, however strong the injunctions of secrecy on the one hand, or the pledge on the other, they will in a day or two become the common talk of the neighbourhood.

VIII. Try to cultivate your mind, so as, should your husband be intelligent and well-informed, you may join in rational conversation with him and his friends.

IX. Think nothing a trifle that may produce even a momentary breach of harmony, or the slightest uneasy sensation.

X. If your husband be in business, always, in your expenditures, bear in mind the trying vicissitudes to which trade and commerce are subject; and do not expose yourself to the reproach, should he experience one of them, of having unnecessarily expended money of which you and your offspring may afterwards be in want.

XI. While you carefully shun, in providing for your

family, the Scylla of meanness and parsimony, avoid equally the Charybdis of extravagance.

XII. If you be disposed to economise, I beseech you not to extend your economy to the wages you pay to seamstresses or washerwomen, who, particularly the latter, are too frequently ground to the earth by the inadequacy of the wages they receive. Economise, if you will, in shawls, bonnets, and handkerchiefs; but never, by exacting labour from the poor without adequate compensation, incur the dire anathemas pronounced in the Scriptures against the oppressors of the poor.

To both Parties.—I. Should differences arise between husband and wife, the contest ought not to be, as it unfortunately too frequently is, who shall display the most spirit, but who shall make the first advances, which ought to be met more than half way. There is scarcely a more prolific source of unhappiness in the married state, than this spirit, the legitimate offspring of odious pride and destitution of feeling.

II. Perhaps the whole art of happiness in the married state might be compressed into two maxims—'Bear, and forbear'; and 'Let the husband treat his wife, and the wife her husband, with as much respect and attention as he would a strange lady, and she a strange gentleman.'

III. I trust much caution is scarcely necessary against flirtations, well calculated to excite uneasiness, doubts, and suspicions, in the heart of the husband or wife of the party who indulges in them, and to give occasion to the censorious to make sinister observations; and it is unfortunately too true, that the suspicion of misconduct often produces fully as much scandal and evil as the reality.

It is a good rule of reason and common sense, that we should not only be, but appear to be, scrupulously correct in our conduct. And be it observed, that, however pure and innocent the purposes of the parties may be at the commencement, flirtation too often leads to disastrous results. It breaks down some of the guards that hedge round innocence. The parties in these cases are not inaptly compared to the moth fluttering around a lighted candle, unaware of the impending danger. It finally burns its wings, and is thus mutilated for life. 'He that loveth the danger, shall perish therein.' 'Lead us not into temptation' is a wise prayer; and while we pray not to be 'led into temptation,' we most assuredly ought not to lead ourselves into it. I know these remarks will be charged to the account of prudery; but, at the risk of that charge, I cannot withhold them.

IV. Avoid all reference to past differences of opinion, or subjects of altercation, that have at a former day excited uneasiness. Remember the old story of the blackbird and the thrush. 'I insist it was a blackbird.' 'But I insist it was a thrush,' &c.

The preceding rules, if as closely followed as human imperfection will allow, can hardly fail to secure happiness. And should only one out of every ten readers profit by them, I shall be richly paid for their concoction.

I cannot conclude this brief essay better than by adding the following admirable advices of Julia de Rougné to her daughter, shortly previous to her death:—

'Sweetness of temper, affection to a husband, and attention to his interests, constitute the duties of a wife, and form the basis of matrimonial felicity. These are, indeed, the texts from which every rule for attaining this felicity is drawn. The charms of beauty, and the brilliancy of wit, though they may captivate in the mistress, will not long delight in the wife. They will shorten even their own transitory reign, if, as I have seen in many wives, they shine more for the attraction of every body else than of their husbands. Let the pleasing of that one person be a thought never absent from your conduct. If he love you as you would wish he should, he would bleed at heart should he suppose it for a moment withdrawn; if he do not, his pride will supply the place of love, and his resentment that of suffering.'

Never consider a trifle what may tend to please him. The greater articles of duty he will set down as his due;

but the lesser attentions he will mark as favours; and, trust me, for I have experienced it, there is no feeling more delightful to one's self, than that of turning these little things to so precious a use.

Above all, let a wife beware of communicating to others any want of duty or tenderness she may think she has perceived in her husband. This untwists at once those delicate cords which preserve the unity of the marriage engagement. Its sacredness is broken for ever, if third parties are made witnesses of its failings or umpires of its disputes.*

FAMILY RELATIONSHIP.

The marriage state is the foundation of one of the most sacred and important institutions in society—that of a family. A family is a little commonwealth, jointly governed by the parents, but under the more special guardianship and direction of the husband and father, who is morally and legally the *head of the house*. To the father the children naturally look for protection, subsistence, advice, example, and encouragement. The father, therefore, has a serious obligation to perform in the proper rearing of his children. He is bound to educate them according to his means, to support them till they are able to depend on themselves, and to have them taught a business, or put in some other fair way of gaining an honest livelihood. The children, on the other hand, are bound to obey their parents, and to exert themselves to make them happy.

Parents are sometimes grievously distressed in consequence of the bad behaviour of their children. Their reasonable hopes are disappointed, their best feelings are tortured. An idle, ungrateful, dissolute son, is such a complicated cause of suffering, as may, if any thing may, lead one to murmur at the order of things. It may be admitted that such a parent is very likely to break out with complaints against the world. This suffering, however keen and biting it may be, is not a natural, but a moral evil. There is a moral wrong somewhere. Is it in the parent himself? Has he watched the beginning of error, and drawn his child off from the descending plane? But, perhaps, the downward course has been long begun upon, and art and deceit have made such progress that the child has been able to elude parental inquiry. This can hardly happen with a watchful parent while his child is under his own roof. Perhaps the downward course has been begun upon when a child is at a distant school, college, or in a place of business, preparing for manhood. If a parent has placed a child where he cannot superintend him, or with those who do not undertake to do this, or who will not if they do, the parent is not excused because others are in fault. A child who is sent away from home, is, as the world now is, always sent into some hazard. The hazard is, when least, that the preceptor, guardian, and master may be deceived. The seductions may be such as to plunge a boy into ruin, even before those who see him daily, and who mean to do their duty, have the least intimation of it.

Evils, such as are here alluded to, may be in some measure unavoidable in the present imperfect condition of society; still a parent ought to do all in his power to obviate them by implanting good habits in his children. It would be well, for instance, if fathers of families would endeavour to give their sons a taste for such a judicious course of reading as would lead them from the contemplation of vicious objects of pursuit. If they do so, and put them in a right bias, they may depend on them acquiring a great deal more useful knowledge after they leave school than they could possibly have learned there. Nearly all the men who have distinguished themselves in the world are found to have acquired their knowledge through private desultory study after leaving their classes; and many, in their autobiographies, trace their good fortune to the taste for reading given them by their parents.

* The above excellent admonitions are from an American work, called the *Philosophy of Common Sense*, by Mr Carey.

A family of children usually consists of the two sexes. There are brothers and sisters. The intercourse which takes place between these parties ought to be of the most friendly kind. They should strive, by mutual assistance and advice, to make each other happy. In many instances, these relations make a very great mistake as to the real good of life, in not cultivating a cordial and affectionate friendship with each other. In early life they are apt to be in each other's way, and to have irreconcilable wants; thus they very soon fall into alienations. They cannot, however, shake off the laws of nature. They must have an interest in each other whether they will or not, and it will essentially promote their mutual welfare to have a kind and gracious one. The common causes of their differences are exceedingly insignificant, and often contemptible. They will see the day when they will so think of them. The time presses hard upon them when they will need counsel, support, and some one to care for them in a manner which none but brothers and sisters can do. When all has gone on well from the cradle upwards, among such relatives, they become to each other not only the most useful friends, but the most agreeable companions. They are the natural confidants, when it would be folly to trust any one whose sympathy and solicitude may change. Brothers and sisters, who are thus bound together by affection, sometimes hazard the connexion by volunteering friendly, but very unwelcome, commentaries and advice. This is a very delicate matter. Giving unasked advice on any occasion requires very great discretion. If one sees that his brother is blundering, there are many modes of so approaching him as to lead him to find that he needs advice, and of putting him in search of it. If there be a right understanding, he will go where he is sure of having the best and the sincerest. To assume a dictatorial authority over a brother or sister, is to inflict a wound on self-love which is not readily forgiven. We have already noticed the value of civility and politeness between such near connexions; and we add, that sincerity and truth are nowhere more profitable and necessary. "Familiarity breeds contempt" is a true saying, and is very apt to find an application of its truth not only in the intercourse of brothers and sisters, but in that among more distant relations. We beg to warn all classes of relations who frequently meet together, against using too much familiarity, against using too little ceremony, against taking liberties with each other. Let them preserve towards one another the most respectful yet friendly terms, if they wish to avoid falling into differences. Let them remember that the quarrels of relations are almost irreconcilable, and that, even when forgiven and in a great measure forgotten, they leave very disagreeable feelings among all parties.

DUTIES OF MASTERS AND SERVANTS.

From the earliest ages down to the present time, there have been different classes of society. As elsewhere explained, this necessarily arises from the very order of society. The well-established and very proper right of inheritance, and the ability which some members of society have to acquire, and which others have not, the difference of education, and other obvious causes, necessarily produce these distinctions. Who among the various classes is the most contented and happy, is quite another matter. There must be some to serve, and some to be served. They are mutually dependent. We hear great complaints, sometimes from masters with regard to their servants, and sometimes from servants with regard to their masters or employers. This connexion is regarded as one of the miseries of life; yet it is not necessarily so. If the connexion produce vexation, there must be error somewhere. We shall first speak of the duties of masters, in which we always include those of mistresses.

It is the duty of masters to cultivate the esteem and affection of those whom circumstances have placed under them. Servants have the same sort of bones,

muscles, heads, and hearts, the same self-love, and the same sensibilities, as their employers. They may not be so refined, still they have rights to be maintained, and must not be tyrannised over, merely because they are in an inferior condition. They have as good a right to be happy as those above them. If they behave with propriety, and do their duty, they should be spared when sick, advised and relieved when in trouble, and be made as comfortable as circumstances will permit. The commands given to them should be plain, clear, uniform, and not contradictory or capricious. They are not to be sneered at, or commanded with virulence and reproach, but mildly, and rather by request. They are also to be treated with uniform civility; but every approach to familiarity with them should be avoided, if respect on both sides is to be preserved. It is always best to let servants know what is their duty, what is expected of them; this being beneficial to both parties. Much mischief is sometimes created by not attending to this rule.

The duties of servants to masters are equally clear. Their entering into servitude is a contract which they engage to fulfil. They are bound to execute all reasonable and proper orders in the line of service in which they are engaged. But besides this, they would consult their interests in being generally obliging and willing to assist in any kind of exigency. A seeming wish to please an employer, goes a great way to compensate for deficiencies in ability. A civil obliging turn is indeed one of the chief virtues in a servant, and is certain to secure the affection of masters and mistresses. A strict attention to an employer's interest, regularity of habits, and perfect integrity both in speech and action, form the principal qualifications of a servant. There is usually much less actual dishonesty among servants than a regardlessness of their masters' interests and time. This is more the case with domestic than other servants. This class of persons, who are chiefly females, are very apt to encroach on the time of their employers for their own pleasure and convenience. If sent an errand, they will spend a great deal of more time in executing it than is necessary. It is an idle love of gossiping which generally produces this great failing among servants, and it is our duty here to admonish them of its impropriety. Their time belongs to their master, and it is dishonest to use it for their own purposes, unless by permission. Speaking with regard to persons in service generally, we are sorry to notice that there is a tendency to reduce the terms of contract betwixt employers and employed, to one of a purely mercenary nature—so much work for so much money. There appears to be a growing inclination to drop all kindness of intercourse betwixt the two classes. The consequence is, that many masters feel perfectly indifferent with respect to giving employment to those who have long served them. The injury is, however, mutual; for, when servants know that they are only valued in proportion to the amount of their actual labour, and that they will be paid off without regret, they care little for a master's interest. There can be no question as to who began this improper system. It originated in servants and workmen endeavouring to establish by violence and intimidation a certain amount of wages for their labour, and which the state of society could not warrant. We earnestly trust that it is not yet too late to restore the ancient bond of sympathy betwixt every description of employers and employed. Individual and social benefit would be the result.

DUTY OF TRUSTING TO OURSELVES.

There is a duty of an important nature which we have to perform towards society; and that is, we must *trust to ourselves*. We have each been endowed with reason to guide us, and hands to work; why, then, unless prostrated with bodily disease, or some other infirmity, should we think of leaning upon others for support or assistance? It would not be desirable to see men shut up their hearts against each other, and each stand in the panoply of his own resolutions,

determined against every friendly appeal whatsoever. It is possible, however, to be not altogether a churl, and yet to take care lest we be tempted into an exertion of benevolence dangerous to ourselves, while it is of little advantage to our friends. Notwithstanding the many ties which connect a man with society, he nevertheless bears largely imprinted on his forehead the original doom, that he must chiefly be dependent on his own labour for subsistence. It is found by all men of experience, that, in so far as one trusts to his own exertions solely, he will be apt to flourish; and in so far as he leans and depends upon others, he will be the reverse. But there are many who do not recognise this principle. They trust only partially to themselves, and are always poking about after large favours from friends. We find them asking loans of money, asking others to be surety for them, asking acquaintances to interfere to get places for them. If they ask for nothing else, they intrude upon their friends to seek advice. Neither physically nor morally do they seem able to exert themselves for their own behoof. This is so contemptible a mode of living, that it cannot be too severely reprehended. Those who depend on others can never succeed in life. In whatever manner they may be assisted, they can never become front-rank men in society. We would earnestly impress upon the young the propriety of depending as little as possible upon prospects of advantages from others, all of whom have enough to do with themselves. It is obviously the duty of every one to think and act for himself, as soon as he attains manhood, and neither be burdensome on relatives nor troublesome to acquaintances. The acceptance of a trifling favour from an acquaintance always lays us under an obligation, which is sometimes difficult to remove. If the acquaintance ever need similar favours, we feel bound to grant them, and perhaps he estimates the original favour so highly, that he thinks we cannot do enough to serve him. In this way hundreds of men are ruined. We would say, accept no favours, unless upon a principle of common courtesy. If you employ others to execute a piece of work, take care to pay them faithfully and promptly, and lie under no obligation to them, otherwise you may be called upon when you least expect it, to make payment an hundred-fold. Be liberal, affable, and kind; but, knowing that you cannot do more injury to society than by greatly injuring yourself, exercise a just caution in giving way to the solicitations of your friends. Never be too ready to convince yourself that it is right to involve yourself largely, in order to help any person into a particular station in society; rather let him begin at the bottom, and he will be all the better fitted for his place, when he reaches it, by having fought his way up through the lower stages.

MAKING A WILL.

Much distress among families is often produced by individuals who have property to bequeath, not making a will or testament. Why such individuals do not make their wills, it is difficult to explain. Perhaps it arises from carelessness and a spirit of procrastination, or a want of resolution in men to make up their minds with respect to how they would distribute their property at their decease. Some may indeed be so foolish as to imagine that the making of their will would hasten the approach of death. From whatever cause it proceeds, it is a highly blameable failing. It is the duty of every person possessing property, whether engaged in business or otherwise, to make a will, and describe in some species of document how he would wish his affairs to be arranged in the event of his dying. There certainly are cases in which men of property would not wish their possessions to be distributed in any other way than as the law would dictate; yet it is a mark of a well-regulated mind to leave a will descriptive of the means to be pursued in the accession to, and management of, their property and concerns. To do so, at least, would often save a great deal of trouble and some expense, and be a preventive of litigation among rela-

tions. We therefore must insist that the making of a will is a sacred duty which ought to be performed, and performed without procrastination. In the midst of life we are in death; no one knows but in an hour hence he may be no more. We beseech fathers of families, and others similarly placed—those even who may have property but to the value of a few pounds—to lose no time in executing their will. By leaving so much as a letter subscribed by their name, to be opened after their decease, they may spare much vexation to those whom they hold dear, they may quench much petty jealousy, much unseemly disputation. In a country such as Scotland, where a wife dying without having had any live children, the one-half of the moveable property of the husband goes legally to her relations, it is incumbent on wives so circumstanced, if they have any love and esteem for their husbands, to make their wills: that is, put in writing a simple expression of their desire that their husbands may inherit the property which belongs to the wife in virtue of their marriage. By an inattention to this easily performed duty, there are many litigations—many widowers ruined.

MISFORTUNES—EVILS.

Evil is a part of the system of things in which we live, and, as such, must be patiently submitted to. Man was intended to be an active creature. One of the grand aims of the Creator in his formation evidently was, that he should never settle down into a sluggish or stagnant state. It would have been easy for the divine power which breathed into him so wonderful a thing as life, to have surrounded him with nothing but blessings, as they are called, so that he would have nothing to do but enjoy himself. But this would not have produced what the Almighty wished, a world in which a rational being was to exercise his faculties, and use his endowments, with a proper regard to a certain end—an account, namely, to be rendered at the close, of what and how he had done. We are here placed between evils which we are to avoid or subdue, and good which we are to aim at and enjoy; and hence, instead of being a set of torpid machines, as we would have been in any thing like a world of perfect happiness, we are in a perpetual state of vigilance and activity, making the fullest use of those mental and bodily properties with which we have been gifted.

If we narrowly inspect the evils or misfortunes with which we are visited, we will find them invariably to be, either of two kinds. Some are the simple result of an occasional or habitual violation of the laws of nature, or an occasional or habitual failure in that vigilance and activity which we are bound to employ for the avoiding of such distresses. These may be called moral evils. The second class are the result of circumstances over which we had no control, and may therefore be called natural evils. Such a division, however, is only necessary in the present state of our attainments as a race; for there can be no doubt that means were intended to be discovered by the ingenuity of man, for the avoidance and neutralisation of all evils whatever; and, therefore, in the case of what we call natural evils, we should only consider ourselves as the victims of imperfect knowledge, and be the more induced to strain after the improvement of ourselves and of our fellow-creatures, so as to obviate these as well as the rest.

Great care should be taken, when an evil befalls us, to ascertain whether it be moral or natural—in other words, whether it be the consequence of our own error, or of circumstances at present beyond our control. Our self-love makes us extremely apt to attribute all our mishaps to the latter cause; but if we are wise, we will not do so. We will rather search back unscrupulously into our own nature, or our own history, for the causes of the evil; and if we find them there, resolve for the future to be more circumspect or more active, so as to make a recurrence of the mischief less likely. The most of the accidents that occur, though they appear at first sight to be natural evils, would be found, on

close inspection, to be moral. The most of the diseases that befall us could be traced to a failure in our duty to ourselves, and are therefore moral evils: the rest, such as cancers, wens, organic malformations, &c., which appear natural and unavoidable, are, we have no doubt, moral evils also. If we knew better, we might probably avoid them, as easily as we can avoid colds. They may be called natural in the mean time, but not so unless we strive to discover their causes, so as in the long-run to obviate them. They are certainly destined to be obviated at last, as many disorders, now understood, formerly were; and we must at present consider them only in the light of an inducement to the exertion of the spirit of inquiry.

There are some evils which we incur through hereditary channels, and are quite beyond our own control. We are charged, for instance, with the seeds of a harassing ailment, or of an early death, by the long foregone and perhaps long repented vices of our parents. But all this may be accounted for on the same principle. It has been intended that our moral natures should be so much improved, that even the possible distresses of a descendant may operate as a check to our wickedness; and what is a contemporary instance of innocent consumption but a warning to prevent us from doing that which may bring future lives into the same hazard? It is hard, in the mean time, for the sufferer; but what can we say against the course of nature? Perhaps the spectacle (and few can be more painful) of a youth dying in his very bloom, in consequence of natural debility derived from weakly parents, may be the means of preventing two persons from putting themselves into the situation for bringing on similar evils. A very high kind of conscientiousness, but one not unattainable even by ordinary minds, is called into force by the contemplation of such a case of unbought distress. A man who has any reason to fear for the validity of his own constitution, will, if fully impressed with a sense of such results, as likely to arise from his quitting a condition of celibacy, condemn himself to perpetual solitude rather than purchase an improvement of his own happiness, at the expense of unreckonable evil to others. Fortunately, society is beginning to look more narrowly into such matters than it used to do; and we do not despair of seeing a time when it will be nearly as infamous to communicate life under certain circumstances, as, under others, to take it away.

There are other evils which affect society, and which do their full part in making this a world of woe. There is squalid, miserable poverty; there is disgusting, lamentable vice; there is horrible crime, public execution, and national war. All these things, it is said, are inevitable; they spring from the nature of man, and from the laws which compel him to dwell in social connexion. Those who say so are shallow thinkers. The world is naturally a beautiful world. But what God has made a paradise for our dwelling-place, mankind have often rendered a desert by their crimes. Nature and revelation alike proclaim that the Creator intended we should be happy; but how has brutal ignorance, vile intemperance, gross crime, and every species of evil desires, blighted our comforts and degraded our immortal being! It has never yet been proved that there must necessarily be poverty, which is the source of many evils. A striking instance of the absence of poverty in a large class of society is found in the case of the Quakers, or community of Friends. With some peculiarities in speech and dress, not worth while to heed, this numerous body of individuals act upon a fixed uniform principle of suppressing the passions. They curb the appetites and headlong impulses of human nature. In this may be said to lie the substance of sound morals. The Quakers, therefore, habitually practise what other classes only theorise upon, at least are seldom performing. The consequence of this guardedness in thought and action is, that although there are many thousands of Quakers in Great Britain, and many thousands in the United States of America, neither in the one country nor the other do we ever

find a Quaker begging in the streets, or an intoxicated Quaker, or any one of this class of subjects and citizens at the bar of a criminal court! The Quakers are, like other people, engaged in the common affairs of the world; they are merchants, mechanics, artificers, mariners, and otherwise employed in the ordinary business of life. They are subject to the same temptations and perversions that we are; yet, by the exercise of a singular degree of prudence, they avoid them. Here, then, is a clear demonstration, that even without the aid of civil power, but by the mere force of moral influence, there is a class of men, in the midst of society, who do escape disgraceful poverty, and who are free from vice and crime.

With regard to death, which is so generally looked upon as an evil, and the last and worst of all, it is in reality no such thing, unless it occur prematurely, which it never would do if men were perfect in the observation of the laws of nature. As the conclusion of an existence which never could have been given if others had not died, it must be regarded as only a part of our earthly destiny, and submitted to accordingly.

INEQUALITY OF RANK AND CONDITION.

When the young grow up, they find society to consist of classes of various degrees of rank and condition; some with titles of distinction, others without any title whatever; some rich, some poor, and many in a middle state between great wealth and poverty. The youthful reasoner perhaps thinks that all this is wrong, and that by *natural right* all men ought to be upon a level. It is proper that not only the young, but others who take up notions of this kind, should be told why these differences originate, and why they exist. Mankind, we may suppose, were originally equal in rank and condition; and they might have remained so, or nearly so, had they continued to remain in primeval barbarity, and lived apart from each other. But it was not in their nature to remain in this condition. According to naturalists, man is a gregarious animal; that is, he desires to live in society. As soon as men began to consort together, they began to separate into ranks and conditions. He who was the bravest was made king; he who was the most clever or the most prudent became the most wealthy; he who was the most idle became the most poor. From this kind of beginning all ranks and conditions sprung; and subsequent events have modified society into what we now see it. It may be said that this explanation would do very well if we now found that those who enjoy distinctions in rank were the cleverest of the people; if we found that the richest were always the most deserving of riches. Here, again, we must apply to human nature.

In one sense, titles are contemptible; they are fantastic trappings which a wise man would not covet. But, on the whole, there are few men possessing that degree of wisdom and self-denial which would lead them to despise titles, or the dignities connected with them, *when applied to themselves*. As far as we can discover, the Quakers are the only people who do not regard these things. The citizens of the United States of America affect to despise titles; yet, it is curious, they give a title of distinction to their chief magistrate, whom they style "*His Excellency*;" they also write *Master*, or its contraction *Mr*, before their names. In this we see a degree of the same vanity and weakness which affects the subjects of ancient monarchies. It would appear that there is a yearning after these follies among mankind. Be it so or not, it is an idiosyncrasy which, from time immemorial, has been seized hold of by rulers for the purpose of stimulating men to deeds beneficial to their country. The prospect of being entitled to write *Sir* before their names, or of being called a *Lord*, induces numbers of individuals to do great and good actions, which they would not do for money. As these titles generally descend to their children, they have a double stimulant to action. Genius not being hereditary, these titles may and do fall into the possession of men of no ability; nevertheless, the stimulant to acquire

titles such as they have, continues to act beneficially, as it is thought, through the nation; and they themselves feel bound to sustain a certain honourable character consistent with their rank.

The principles of human nature apply in a similar manner in solving the mystery, why there are men enjoying riches which they never wrought for, and may be undeserving of. Riches consist of that part of the surface of the earth which can be used for human habitation and their appendages; of that part which can be used to produce vegetation; of that part over which, and near which, there are flowing waters capable of imparting motion; they consist of all personal estate; and of money, the agreed representative of all property, which is, at the same time, property in itself. Possessions of these various kinds are acquired by inheritance or by industry. Right by inheritance is not wrong. Would any rational mind maintain, that, when the father of a family, or any one who has no family, has acquired property, and dies, that it shall belong of right to any and to all who can get possession, by fraud, force, or whatsoever other means they may? Society could not be held together if such were the rule of right. It is at once apparent, that if such were the rule, there would be nothing to contend for, because all inducement to acquire for the benefit of one's family and connexions would be annihilated. Society would be forthwith reduced to barbarism. The right to acquire, and the right of inheritance, are wisely ordained to be a necessary consequence of society, and one of its strongest motives to act to useful ends.

If it be irreconcilable to justice, to convenience, and to the common good, to take by fraud or violence that which the dead must have left behind them, much more so is it to take from the living, by like means, that which they can honestly acquire by the exercise of their own industry. If a member of a community were always liable to be despoiled of the fruits of his labour, the great principle of the system of being to which man belongs would have been misplaced: there would have been no sufficient motive to action. If one would know what society would be, if such were the law and the practice as to property inherited or acquired, he must visit countries steeped in barbarism, and on which the light of Christianity does not shine.

It is contended by some persons that there should be a periodical division of land and property, and that every member of the community shall have an equal share. How often should this division be made? Shall it be made once a-year, once in ten years, once in fifty years? Why should it be made at one time rather than at another? Suppose it could be made, and were made, it must be but a very short time before it ought to be made again, if the reason for making it be, that some have more and some less, and that some are rich and some poor. One must be wilfully blind not to see that either the whole action of society must stop, or that inequality of condition would arise in a single year, perhaps in a single month; and even such inequality as would call for a new division. In a country where the spirit of enterprise and speculation has an unrestrained agency, the causes of regret are, that sad reverses occur, and that property changes hands too often, rather than that it is unreasonably held in the hands of a few of their successors. A small number of generations is sure to bring equality, considering our community as a continuing one. Thus, property comes and goes, in this country, as fast as any one can reasonably desire to have it. The changes which are seen, as to the ownership of it, are regulated by authority far wiser than any of man's institution.

ON FORMING OPINIONS.

Opinion signifies belief. There are good and bad opinions. It is our duty as rational beings to cultivate good or correct opinions upon every subject, and to eschew those which are of a contrary description. There is nothing more easy than to form hasty, inaccurate opinions, but it is very difficult to form a correct

belief on many topics. Opinion is found to be more or less dependent on times, circumstances, and bodily temperaments. It frequently arises out of prejudice, and is often influenced by impulse. When we form an opinion upon any subject, we are inclined to believe that all opinions of an opposite character have been, and are, erroneous. We are apt to laugh at every body's opinion but our own. All this betrays a deficiency of sober reflection, an ignorance of the history and faculties of mankind, and a want of knowledge of the world. The people of every country possess opinions favourable to their own fashions, customs, laws, and religion, and unfavourable to those of other nations. A love of one's own country is certainly a commendable feeling, but it should be a love arising from examination and conviction, not from prejudice. The Hindoo worships the river Ganges. We, by our education, know that this is nonsense. The bigoted but conscientious Turk will go to death upon it, that Mahomet was a true prophet. We, by our superior intelligence and reading, know that Mahomet was a vile impostor. The people who lived in our own country a hundred years ago were of belief that certain old women, whom they termed witches, could, by supernatural powers, raise tempests at sea and land, and malevolently interrupt the course of human affairs. The people who possessed this belief were perfectly conscientious in their opinion; yet we know that this opinion was a gross absurdity. We know that our ancestors believed in an impossibility. Opinion is therefore, as we see, a thing of time and place. The opinion that is supposed to be right in one century, is wrong in the next. What is considered to be a right opinion in Asia, is thought wrong in Europe. What is deemed a correct and praiseworthy belief in Britain, is reckoned an absurdity in France. Indeed, it is often seen that the opinion which is held good in one district of a country, is looked upon with contempt in other districts—so that the whole world is found to be covered, as it were, with a variety of opinions and shades of opinions, like the diversified colours by which countries are depicted in a map. Opinion, we have said, is also dependent on temperament of the body. This is a melancholy truth. A fat and choleric man does not think in exactly the same way as a lean man. A man who enjoys all the comforts which opulence can purchase, has a tendency to think differently in some things from a man who is suffering under misfortunes or poverty. So strangely constituted is the principle which governs opinion, that most men have reason to alter their opinions on many points in their progress through life. They form an opinion in youth, from which in manhood they depart, and form another; and this other they modify into something else as old age comes upon them.

What does all this wonderful contrariety of opinion teach us? Since we see that opinion is dependent on the locality of our birth, on the age in which we live, on the condition in which we may chance to be placed, and on the physical qualities of our bodies, have we therefore no power over opinion? Must we be its slave? These are questions of a solemn character, and we must answer them soberly. The contrariety of opinion existing in times and places teaches us, in the first place, *humility*, which is the foundation of many heavenly virtues. It shows us that the opinions which we may form, particularly on abstract subjects, may possibly neither be the most correct nor the most enduring. Perhaps what we have taken up and cherished as our opinion may after all be a delusion. In learning a lesson of humility and distrust of our own style of thinking, we are impressed with a tender regard for the opinions of others—opinions which, most likely, have been taken up on grounds equally conscientious with our own.

Although opinion is commonly dependent on those contingent circumstances which we have noticed, it cannot be allowed that we have no power over it. We have a power over the formation of opinion to a certain extent, and it is our present object to show how this

power can be exerted in order to enable us the better to fulfil the duties of life. The reason why opinion is so illusory in its nature, is, that mankind have ever been excessively careless in the adoption of their opinions. They are in the habit of picking up random ideas, which they mould into an opinion; and after having made up their minds, as they call it, on what *they think* is their opinion, they will listen to no explanation of the opinions of others. Their obstinacy, their self-conceit, their self-interest, their wish to please the party to which they have attached themselves, induce them to hold fast to their original opinion, until time or experience, in all likelihood, wear it down, and its absurdity is secretly pressed upon their notice. But even after its absurdity is disclosed, they are sometimes ashamed to say they have altered it; and so, perhaps, they have one opinion which they keep locked up in their bosom, and another which they bring into daily use, and flourish before company. In the apposite language of Scripture, these men war against the Truth.

It is our duty as good members of society, and with a view to self-respect, to be very cautious in the formation, and, most of all, in the display of our opinions. Many excellent men, on arriving at middle life, have deeply regretted that they should have heedlessly published their early and hastily-formed opinions in youth. They had reasoned, as they thought, soundly, but it was without a knowledge of the world, or its history. Speaking to the young, we would say—while yet under the training of parents, guardians, and teachers, it is your duty to receive with confidence the instructions by which it is attempted to enlighten your minds, and to put you in the way of well-doing. But these friends of your youth will probably tell you that when you pass from under their guardianship into the active scenes of life, you become a responsible being—responsive alike to human and divine laws; and that you must now think for yourself. At this critical period of your existence, you have every chance of coming in contact with the idle, the dissipated, the frivolous, who will try to make you embrace erroneous opinions, and who will possibly put the most mischievous books into your hands for perusal. Do not be led away by such machinations; neither be dismayed by the number of wits or profane jesters who may assail you. Do your duty manfully. In order that you may attain a correct opinion on the great debateable subjects that you will hear rung in your ears through life, begin a course of reading those good and authoritative works which intelligent friends will recommend to your notice. Take every opportunity of cultivating your understanding, of enlarging your ideas, of banishing prejudices. Look always at the different sides of a question; for you must remember that there are always many ways of telling a story. In proportion as you advance in your private studies, and acquire a knowledge of the passions and conduct of mankind, you will more and more be able to form a correct opinion. There is one thing which you will learn with surprise from this kind of experience, and that is, that many, though holding different opinions, are driving towards the same end in the main. They have only differed upon trifles, and perhaps fought about mere words. This is one of the strange weaknesses of the human race, into which you will find it difficult to avoid falling. The more that you learn, the more will you see cause to entertain a liberal view of the opinions of others. It is the exercise of this liberality of mind which forms a distinguishing trait in the manners of our country. By the British constitution, every one is allowed perfect freedom of opinion, a gift above all price, which it is our duty not to prostitute or abuse. Let us form our opinions on solid grounds of conviction—let us cherish these opinions to the adornment of our lives—and let us so maintain a due regard for the opinions of others, that we show forth, in our feelings and actions, that most excellent of all virtues—CHARITY.

These observations apply indifferently to various subjects upon which opinions may be formed; and we

would, in conclusion, beg to say a few words, in particular, on opinions of a political nature, which are the most difficult of all to be correctly formed. Political opinions are applied to the theory and practice of national government. The policy of national government is not an exact science to be learned, as some would imagine. It is more a fashion than a science. It is a thing dependent on time, place, and other circumstances. The form of government which suits one age or country would not suit another age and country. Some nations are best governed by a despotism, others by a mixture of monarchy and democracy, others by a pure republicanism; but, as we say, what is best at one time is not best at another. The genius and necessities of every people are subject to change, and consequently their governments change with them. If we feel the force of these facts, we will be cautious how we assume an unalterable opinion upon any mode of administering government. The young are particularly liable to take up notions on this subject which they afterwards feel inclined to fall from. We would admonish them to read and digest the history of their country, and reflect well upon the genius of the nation, before they come to a determinate opinion in politics. They will learn, as they advance to maturity, that in nothing is there such a mass of duplicity and affectation as in political matters. They are therefore called upon, by duty, to examine extensively, and probe deeply, the grounds upon which they form their opinion. They will find it much the safest course, as already expressed, to think lightly in the matter till they have had some experience of the world, and been convinced by the evidence of their senses. National exigencies sometimes call upon us to engage more deeply in politics at one time than another. Discretion must here be our guide; yet there is generally greater danger in our wasting much precious time on political disquisition, than in falling into an apathy upon public affairs. He is a wise man who knows how so to guide his steps as to preserve himself from falling into either extreme. Every one who has been for a long series of years politically busy, will acknowledge, that though he thinks he was right in the main (in which opinion he may be right or wrong), yet, that he has spent many busy hours and anxious thoughts on subjects, which, looked back upon, are seen to have been profitless and insignificant.

DUTIES WHICH THE PEOPLE OF ONE COUNTRY OWE TO THOSE OF ANOTHER.

It is seen that all the people of the earth belong to some one of the many nations with which it is covered. It is also seen that nations are generally separated from each other, not only by language, manners, customs, religion, and forms of civil government, but also by geographical boundaries. The division of mankind into nations is natural, and possesses obvious advantages. There is a limit beyond which the government of a nation cannot well be administered. By being confined within certain limited bounds, the national institutions may be improved, security and prosperity promoted, and the interests of the people advanced. We frequently find that the people of one nation live at enmity with those of another nation. We find many at open war with their neighbours—that is, they are resorting to brutal physical force to settle a dispute. These are evils deeply to be deplored. Nations have mutual wants, which a mutual intercourse and trade will obviate. They have similar interests at stake. Their inhabitants all alike belong to the great human family, and should live at peace with each other. But ambition, and many evil passions—strife, malice, and uncharitableness—are continually in operation to retard their advancement towards a universal philanthropy. National war is the heaviest curse which afflicts humanity. It leads to enormous debts and taxations, and in reality is the beginning of all kinds of distresses among the people. Yet the people have been frequently very clamorous for war. We say *have been*, for we hope that this sentiment will in future be otherwise regulated.

We ought to impress upon our minds a surpassing horror of war. Let us think of it as the scourge of the human race, and as one more destructive, physically and morally, than the most virulent epidemic. Were the inhabitants of countries duly impressed with these feelings, did they reflect upon the blessings which are showered upon nations during a lasting peace, they would henceforth resolve to oppose, by every constitutional means, the commencement of wars by their governments. Besides the actual loss of lives and of property to a nation during war, it is incalculable the injury sustained by society by such an infliction. A war of a few years' duration may retard intellectual improvement for a century. We hold, therefore, that it is the duty of every man to discountenance such a system of folly. He cannot be a lover of his country, he cannot be the friend of moral cultivation, who would countenance such an idiotic process of settling quarrels between intelligent nations. According to a rational view of men's condition in separate nations, war can in no case be reconcilable with social happiness, unless on the obvious principle of self-defence. So long as there remain such masses of ignorance over the earth, so long, we are afraid, force must be employed to preserve the little spots of civilisation from the flood of barbarism which might overrun them. May it be anticipated, however, that this urgent necessity will not exist much longer! How glorious would be the prospect, if universal peace were permanently established! We should find one nation instructing another in all the arts and sciences of which it was itself master: we should find an honourable spirit of emulation running through the whole; and all shaping their policy so as to promote the most beneficial intercourse in commerce, literature, and refinements. In the present state of things, as far as it can be accomplished, a kind and friendly international communion is a high moral duty. It is our duty to look with an eye of charity on national peculiarities. We have no right to insult the feelings of the people of any nation, however strange their language, their fashions, or their customs may appear to us. We have likewise no right to taunt them with any apparently improper characteristics in their forms of government. It is our duty to consider them as entitled to live and act according to their own fancy, as independent responsible beings. To write, print, and disseminate any scurrilous jests tending to lower them in general estimation, is not only immoral, but inconsistent with the principles of honour, which do not permit any one to be struck who cannot defend himself. When we therefore insult a foreign nation by our obloquy, we commit the mean and cowardly action of injuring a party which has no means of redressing the grievance.

RECREATIONS AND AMUSEMENTS.

We have often had occasion to show, that this state of being is one of alternate action and repose. There must be serious action, and there must be amusements. It was intended that mortals should be pleased and happy, if they deserve to be so. Those who maintain that life is to be an uninterrupted scene of labour and gravity, are, we hope and believe, entirely mistaken. We discern nothing in the natural world, nor in man's peculiar constitution or relations, which gives the least countenance to such an opinion. Amusement, like every thing else in which free agency is concerned, may be innocent and grateful, or improper, pernicious, and introductory of the worst of evils. Young persons must have the former, or they will seek out the latter. It is the duty and the interest of parents to lead children to take pleasure in such things as can be approved of, and to divert children from such as must be injurious to them, and afflictive to those who are deeply interested in them. We apprehend that there may be persons, and classes of persons, who will disagree with us on this subject, as they may have done on some which have been already touched upon. We should deeply regret to displease any one; but on a matter so impor-

tant as the making good citizens and good moral agents out of children, one should not hesitate to speak frankly and sincerely. If wrong, persons better able to judge will take care that no evil visits them in consequence of such error.

Amusements are physical or mental. It may be more proper to say, that there may be, first, amusements which are intellectual, and, second, such as consist of some bodily motion, in which the mind is more or less interested. If there be such distinctions, athletic sports may be of the second sort. The simple use of the eye, of the ear, and of the imagination, may be of the first sort. It is believed that all amusements must have some contemplated end or result, whether that be defined and certain, or contingent. We believe so, because every thing in this world seems to be moving on to some purpose. One who is acting without knowing for what, is neither labouring, nor amusing himself, but is trying to get rid of himself, and of time. The most captivating sports are those which are contingent; that is, sports or occupations wherein the result may be highly favourable or otherwise. No one engages in them without expecting to come out on the successful side. Hence, hunting, fishing, horse-racing, and gaming, are of this order. The hope of success is a very high excitement, but the mortification and distress of failure ever far exceed the pleasures of success. There is a tendency to discourage out-of-door sports. This is certainly wrong. If not carried to excess, they are among the most salutary and pleasing amusements in fine weather.

Every one admits that the mind and moral faculties are to be developed, and strengthened, and made to do the best, by exercise. This is equally true of physical power. Every action which it can be proper to do at all, ought to be done in the best way, otherwise we do not answer the end of our being. In the vegetable and animal departments, all proper care and cultivation tend to use and beauty. Is there any reason why the physical powers of man should not have care and cultivation to the same ends? Those who prefer a stooping, lounging, awkward, graceless figure and motion, may be on one side of the question; those who think that it was intended that man should be an upright, easy, frank, comely, and convenient being to himself, and pleasant to all within whose observation he may come, will be on the other.

Although the frame of man is so made as to permit him to assume an endless variety of positions, and to apply his strength in all of them, he does, or should, return always to an upright position. No essential deviation from this position can possibly be a natural one, but for a temporary purpose. This is proved by the framing of the human bones. This framing shows, that, when one walks, it was intended that he should be perpendicular; if he walk in an inclined position, he has not only to move himself, but to resist the power of gravitation at the same time. The muscles, in such case, have a strained and unnatural duty to perform. It seems to have been intended, by the same sort of proof, that human beings should walk with the lower limbs, that is, from the hips downward, and not with an unmeaning and ungraceful action of the whole person, as is often seen to be done.

Dancing.—As to the best modes of acquiring strength, case, and grace, there may be very different opinions. There are many who think the discipline of *dancing* a proper mode, and others who think this highly improper. We would not run against any opinions, whether well or ill founded. But as to dancing, just like every thing else, it may be misused and perverted, or be made to be an innocent, healthy, and commendable accomplishment. There is no mode so much within the reach of the community, in general, as this. Properly taught, it brings out the power of the muscles, and gives them their natural action: all natural motion is graceful. Why should not man conform to this general law of nature? Dancing well is one mode of conforming. Possibly it is considered frivolous and corrupting. Nothing is frivolous in this system of being which

is innocent, pleasing, and adapted to promote healthy action. Persons who are capable of being corrupted by dancing, will certainly find some much more effective mode to become so, if this be denied to them. Dancing among the very young is usually conducted under the eye of discreet seniors, and well-educated adults need no supervision in dancing, but that of good sense and their own self-respect. But suppose dancing could in any case be perverted, so may every thing else be. If we are not to do any thing till it is impossible to err in doing it, what will there be for any one to do?

Music.—It is one of the most convincing proofs of the benevolence of the Deity, that he has so formed the human ear as to make it capable of finding a rational and elevated pleasure from the action of sound. There might have been organs of speech, and ears to hear, without imparting to the ear the power of knowing and delighting in music. It must have been intended that this gracious gift should be used, and (most probably) as one mode of praise and thanksgiving as well as for innocent pleasure. Music is action; it is action to some end; the end is innocent and delightful. The enjoyment has the double advantage of being solitary and social. Music may be made to produce a sense of high moral feeling, and it may be made to produce a feeling of very opposite character. The same rules must be applied to this subject as to all others, that every thing was created, and for some good and wise purpose; and that every thing must act, and will act, to some useful end, if human ignorance or error do not interfere. We therefore contend that the power to make music is to be cultivated, and its benefits to be thankfully enjoyed.

It is consistent that man, as he is so superior to all other animals, should be alike superior in the making and enjoying of musical sounds. He undoubtedly is so. His voice (it would be more proper to say woman's voice) includes all the sweet sounds which can be made by all other animals. He has, by cultivating this power, by applying the atmosphere through the human lungs, and by delicacy of touch, and by bringing substances in contact with each other, and by sending the wind through that wonderful work of his own hands, the organ, found the means of rendering tribute to the Most High, and of softening and purifying his own heart. No doubt, music was given to mortals for their amusement, and that it is their duty to take it in that light, and be thankful for it.

Games.—Games at cards are a very common amusement. They may be innocent, but there is nothing to recommend them. They give no action to the body; they are a very humble occupation for an intelligent mind. Whether the chances in distributing fifty-two pieces of spotted pasteboard fifty successive times in three or four hours, shall possess some of the engaged with fortunate pieces, and others with unfortunate ones, can hardly be said to be doing any thing to any useful end. When the sport is over, the thing proved or arrived at is, that in this use of four hours of a short life, A counted so much, and B so much. This, however, is not the end usually proposed in playing cards. The cards are only the machinery which, with more or less skill, submits to the laws of chance the result of emptying one man's pocket and filling another's. A passion for this kind of gaming extinguishes, or converts into a withering curse, every fine feeling of the human heart. Time, health, property, the proper use of the tongue, character, self-respect, and peace of mind, are the sacrifices made at the gaming-table. Unnoticed by the miserable victim, the shackles of habit are put on, which no earthly power can unrivet. When the gambler's last shilling is gone, he starts, as from a dream, into a full sense of the complicated misery and ruin in which he has involved himself. He must then devote himself to infamy, and submit himself to the power of a gravitation which will bring him inevitably to the bottom of its abyss. The evils of gaming may be judged of by the number of suicidal deaths which it occasions, especially in the great cities of Europe.

All gaming for property leads, in proportion to its character, to such results. The means of gaming, and especially with cards (as they are the easy and most common implements in use), are regarded with the abhorrence which is associated with them by all persons who feel an interest in the young. The young and the middle-aged have no need of cards for amusement. They may have many amusing occupations which are innocent and improving. There may be persons in an advanced time of life, who are beyond the seduction of gaming, to whom the interest of a game of cards may be an innocent and welcome amusement. Undoubtedly, friends who are met for social purposes, and who have nothing better to do with their time, hands, and minds, may play cards in a manner to give no offence to themselves or others. But it is pleasing to know that the state of improvement is such, that in most social meetings there are higher entertainments than that which cards afford, and which are justly in higher esteem.

There might be games, one would think, adapted to amuse children, and to be at the same time innocent and useful ones. Whatever they are, they must be consistent with the principle which requires a beginning, an interesting succession of circumstances, and a result worth attaining. Children must be busy. To require of them to be still, is to require what nature has forbidden. To place a child on a hard bench, and tell him to sit still there two or three hours, without any employment for his hands or mind, is as great a violation of natural law as to require of him to stand on his head for the same length of time. There is an obvious want in the means of amusing children; and we apprehend that it arises from disregarding the principles on which the construction of physical and intellectual being rests. If there were an extensive workshop, provided with every variety of tools, with a proper superintendent, to which boys might resort on some proper arrangement, and where they could make articles for themselves, there can be little doubt that it would be diligently frequented. The reason is, that their little efforts would be to some end, and by natural means. On the other hand, the gymnastic machinery is fallen into disrepute. These exercises are uninteresting repetitions to no end, except with those who know that bodily motion must be had to secure health. In such case they endure the labour for the end in view. But the amusements of the young must be of a nature to secure action to an innocent and useful end, and health will take care of itself. Perhaps there may be some persons who can follow out this matter, and invent rational amusements. They would deserve to be regarded as benefactors, and would probably find a substantial reward. We cannot but remark that there is one game, which is one of the most interesting and healthful that can be played—that of tennis, or hand-ball. There are many things to recommend it; and among others, it is one sufficiently interesting to be played for itself, without adding to it the zest of winning or losing any thing but the game. We incline to think that it is the game, of all others, which deserves the patronage of colleges and seminaries, and is well adapted to develop the physical force.

Conversation.—The principal amusement of rational people is the interchange of thoughts by speech or conversation, which word is made out of the Latin words *con* and *versor*, and means literally *to be turned to or with*. The principle of this amusement is found in the law of association of thought. Intelligent persons can always make a conversation. The only difficult step is the first; that ought not to be so considered. Persons who are skilled in the art of talking can always give it a direction. The purposes of conversation are, to put one's self in the way of learning something; to impart something that others want to hear; to form opinions on interesting subjects; to settle the merits or demerits of public action; to recount amusing or extraordinary facts, &c. &c. Every human being knows something which he is willing to tell, and which any other that he is in company with wishes to know; or which, if known

to him, would be amusing or useful. To be a skilful conversationalist, one's eyes and ears should be busy; nothing should escape his observation. His memory should be a good one, and he should have a good-natured willingness to please, and to be pleased. It follows that all matter of offence in conversation should be avoided. The self-love of others is to be respected. Therefore, no one is tolerated who makes himself the subject of his own commendation, nor who disregards the feelings of those whom he addresses. There is as much demand for politeness and civility in conversation as in any other department of social intercourse. One who rudely interrupts another, does much the same thing as though he should, when walking with another, impudently thrust himself before his companion, and stop his progress. Under favourable circumstances, and among persons who know how to train a conversation, there are few if any amusements more grateful to the human mind. We need not say any thing of the amusement derived from reading. It is very properly one of the standard amusements of persons of all ages. The influence of the press on the character of a country is not to be measured or calculated. It is strikingly true of this admirable invention, as it is of so many other things in natural and moral agency, that, *well used*, it is an inestimable blessing; ill used, the corrupting demon of social life. Happily, attention to the proper wants of the young has required of the press its action for their benefit; not as to books of study only, but sheets of amusement.

RELIGIOUS OBLIGATIONS.

Religion signifies a system of faith and worship. Religion arises from man's perception of his relation to the system of being of which he is a necessary part. The presence and influence of religion is to be felt and manifested throughout the duration of human life, in all that is thought and done, with a view to a happier and more perfect state of existence after death. Just conceptions of the character and attributes of the Deity are of the utmost importance, especially to the young, whose minds require to be led aright in all that pertains to the great truths of religion. The religion professed in this country is Christianity—the most cheering, the most noble of all faiths. The books to which we point for instruction in the religion of Christ are those of the Old and New Testament. To them the instructors of the young will direct the religious studies of those under their charge, as may best seem fit. Besides inculcating religious obligations, these works furnish us with the most perfect system of moral duty ever promulgated. The sum of the earliest delivered moral law is comprehended in the Ten Commandments, which are as follows:—“1. Thou shalt have no other gods before me.—2. Thou shalt not make unto thee any graven image, or any likeness of any thing that is in heaven above, or that is in the earth beneath, or that is in the water under the earth: Thou shalt not bow down thyself to them, nor serve them: for I the Lord thy God am a jealous God, visiting the iniquity of the fathers upon the children unto the third and fourth generation of them that hate me, and showing mercy unto thousands of them that love me, and keep my commandments.—3. Thou shalt not take the name of the Lord thy God in vain; for the Lord will not hold him guiltless that taketh his name in vain.—4. Remember the Sabbath-day, to keep it holy. Six days shalt thou labour, and do all thy work: But the seventh day is the Sabbath of the Lord thy God; in it thou shalt not do any work, thou, nor thy son, nor thy daughter, thy man-servant, nor thy maid-servant, nor thy cattle, nor thy stranger that is within thy gates: For in six days the Lord made heaven and earth, the sea, and all that in them is, and rested the seventh day: wherefore the Lord blessed the Sabbath-day, and hallowed it.—[By the practice of Christians, the Sabbath has been transferred to the first day of the week.]—5. Honour thy father and thy mother, that thy days may be long upon the land which the Lord thy God giveth thee.—6. Thou

shalt not kill.—7. Thou shalt not commit adultery.—8. Thou shalt not steal.—9. Thou shalt not bear false witness against thy neighbour.—10. Thou shalt not covet thy neighbour's house, thou shalt not covet thy neighbour's wife, nor his man-servant, nor his maid-servant, nor his ox, nor his ass, nor any thing that is thy neighbour's."

Such was the sum of the moral law, until Christ added to it a number of the most transcendently excellent admonitions, and which are found scattered throughout the history of his ministrations in the four gospels in the New Testament. The chief moral which he inculcated was, "Whatsoever ye would that men should do unto you, even so do unto them; for this is the law and the prophets." But the whole of his sayings breathe a similar spirit of benevolence and gentleness. He preached, for the first time that it had been done on earth, the doctrine of "peace and good-will towards men," that is, universal love and peace among all mankind. "Ye have heard," said he, "that it hath been said, Thou shalt love thy neighbour, and hate thine enemy: but I say unto you, Love your enemies: bless them that curse you: do good to them that hate you: and pray for them which despitefully use you and persecute you." Again, he said, "Blessed are the poor in spirit, for theirs is the kingdom of heaven: blessed are they that mourn, for they shall be comforted: blessed are the meek, for they shall inherit the earth: blessed are they which do hunger and thirst after righteousness, for they shall be filled: blessed are the merciful, for they shall obtain mercy: blessed are the pure in heart, for they shall see God: blessed are the peacemakers, for they shall be called the children of God: blessed are they which are persecuted for righteousness' sake, for theirs is the kingdom of heaven: blessed are ye when men shall revile you, and persecute you, and shall say all manner of evil against you falsely for my sake." In this manner he taught the great necessity for being humble and lowly in spirit as the basis of all virtue and social happiness. He likewise inculcated, at different times, the necessity of putting away every thing like ostentation in doing good actions. He tells us not to give our alms before men, but to bestow them in secret; not to pray ostentatiously in public, but in a private place. No one, until he appeared, ever pointed out that there was no difference betwixt actual transgression and the wish to transgress. He tells us that sins of the heart are equally punishable with the commission of an offence. He likewise taught that men "cannot serve two masters," that is, do evil actions, however apparently trivial, and at the same time be good men. To break "the least of the commandments" is to be reckoned equivalent to breaking the whole; and it is further said, it is impossible that our obligations to God can be accepted of so long as we live at enmity with a brother; that is, having a quarrel with any one. "Leave thine offering before the altar, and go thy way; first be reconciled to thy brother, and then come and offer thy gift. Agree with thine adversary quickly, whilst thou art in the way with him." Who among us, may we ask, keeps this saying in remembrance? Do all who attend the public worship of God hold it in mind?

Again, he says that we are equally to avoid hypocrisy, or a pretence of self-righteousness and ability to show our neighbours their faults, before we have put away the same or other faults from ourselves. "Hypocrite, first cast the beam out of thine own eye, and then thou shalt see clearly to cast out the mote out of thy brother's eye. Judge not, that ye be not judged." How valuable are these reproofs! Continuing to admonish us of the danger of hypocrisy, he says that we shall know men by their fruits; that is, we shall know them by their actions, not their words. "A good tree cannot bring forth evil fruit, neither can a corrupt tree bring forth good fruit: therefore by their fruits ye shall know them. Not every one that saith unto me, Lord, Lord, shall enter into the kingdom of heaven; but he that doeth the will of my Father which is in heaven." We

are likewise told that there must be no stop to the extent of our forgiving of injuries. Being asked if we should forgive an injury for seven times, he said to those about him, "I say not unto thee, until seven times, but until seventy times seven;" by which we are to understand that there is to be no limit to our forgiveness. Three things, we are told by St Paul, are essential—Faith, Hope, and Charity, but that the greatest of these is Charity, or a disposition to think well of our neighbours whatever may be their actions. It is also variously inculcated that charity is the first of the Christian virtues. Personifying it, it is said, "Charity suffereth long, and is kind; charity envieth not; charity vaunteth not itself, is not puffed up, doth not behave itself unseemly, seeketh not her own, is not easily provoked, thinketh no evil; rejoiceth not in iniquity, but rejoiceth in the truth; beareth all things, believeth all things, hopeth all things, endureth all things."

CONCLUSION.

We have now given an elucidation of what we consider to be the principal duties we are called on to perform during life, both to ourselves and to others. The subject is by no means exhausted, yet enough has been said to afford human beings a view of what line they ought to follow in the pursuit of individual and social happiness. The object we held in view has been accomplished. We have, to the best of our ability, put young and old, high and low, rich and poor, in the way of executing their temporal duties. We hope we have shown that if man be not a happy, a grateful, a satisfied being, he must accuse himself, and not complain that the system of being to which he belongs is wrong and malevolent. We have attempted to prove that man, individually and socially, is capable of improvement; that he has removed himself from his original condition, and has advanced far in disclosing his own powers, and in applying them in the promotion of his own happiness. But it has to be added, that he has still much farther to go in the same course, that the way is known to him, and that there are no obstacles in it which he may not remove. We do not believe in the perfectibility of mankind. The crimes and follies, which affect even the most cultivated of our race, tell us too plainly that there is a natural bias towards evil, which it requires the utmost skill on the part of religion and reason to counteract. The passions ever seem to stand as a barrier against human perfection, and it is only by their due regulation that we can gain so much as comparative worldly happiness. Yet it is incalculable to what extent the exaltation of the mental faculties may be carried by systems of education, and to what extent the community may be purified of its vices. Let us hope that nothing may occur to interrupt the physical, the intellectual, and moral improvement of society, which is now so happily in the way of advancement.

NOTE.—The former article was an abstract from the Moral Class-Book of Mr William Sullivan, a work published at Boston, in the United States. The present is partly original, and partly selected from the same production. Excellent as Mr Sullivan's book is, it is singularly deficient in the inculcation of some of the principal public duties of life, and is in many parts adapted only for the perusal of American readers. The heads in the present article, Duties as Subjects, as Electors, as Jurors, as Masters and Servants, Conduct at Public Meetings, Making a Will, Misfortunes and Evils, Inequality of Rank, Duties which the People of one Country owe to those of another, Duty of Trusting to ourselves, Religious Obligations, and Conclusion, are the composition of one of the Editors, as also a number of passages in other places. It is humbly trusted that both numbers will be found to form the most complete as well as the most applicable body of admonition on the moral duties ever given to the public; and that parents and teachers of youth will find it available in their purposes of intellectual cultivation.

LIFE AND MAXIMS OF FRANKLIN.

PARENTAGE AND BOYHOOD.

BENJAMIN FRANKLIN was born at Boston, in New England, North America, on the 17th January 1706, and was the youngest but two of a family of seventeen children, two daughters being born after him. His ancestors, as far as they can be traced back (at least three hundred years), were petty freeholders at Eaton, in Northamptonshire; but if we may judge by the surname of the family—the ancient Norman appellation for a country gentleman—we may conclude they had originally been of some consequence. After the Reformation, the immediate progenitors of Benjamin continued zealously attached to the Church of England till towards the close of the reign of Charles the Second, when his father Josias, along with his uncle Benjamin, became dissenters. These men were both bred to the trade of silk-dyeing. Josias married early in life; and about the year 1682 he emigrated, with his wife and three children, to America, on account of the persecutions to which he was exposed for his dissenting principles. On arriving in New England, he embraced the occupations of soap-boiler and tallow-chandler, of which businesses he previously knew nothing, but only from their being at the time the likeliest to provide maintenance for his increasing family. He appears to have been a man of great penetration and solid judgment; prudent, active, and frugal; and although kept in comparative poverty by the expenses of his numerous family,

was held in great esteem by his townsmen. In no respect was his practical good sense more conspicuous than in the education of his children; and his illustrious son frequently alludes, in terms of thankfulness and gratitude, to the many exemplary precepts and sound moral lessons he received while under the paternal roof. The following passage may be read with no little instruction by the heads and members of all families similarly circumstanced:—"He was fond of having at his table, as often as possible, some friends, or well-informed neighbours, capable of rational conversation; and he was always careful to introduce useful or ingenious topics of discourse, which might tend to form the minds of his children. By this means, he early attracted our attention to what was just, prudent, and beneficial in the conduct of life. He never talked of the meats which appeared on the table; never discussed whether they were well or ill dressed, of a good or bad flavour, high-seasoned or otherwise, preferable or inferior to this or that dish of a similar kind. Thus accustomed from my infancy to the utmost inattention to these objects, I have since been perfectly regardless of what kind of food was before me; and I pay so little attention to it even now, that it would be a hard matter for me to recollect, a few hours after I had dined, of what my dinner had consisted. When travelling, I have particularly experienced the benefit of this habit; for it has often happened to me to be in company with persons, who, having a more delicate because a more exercised taste, have suffered in many cases considerable inconvenience; while, as to myself, I have had nothing to desire." Benjamin was at first designed to be a clergyman, and at eight years of age was put to the grammar-school with that view, having previously been taught to read. His uncle Benjamin, who had likewise emigrated, encouraged this project. This individual appears to have been an equally eccentric and ingenious man. He cultivated the Muses with a success that gave himself, at least, entire satisfaction. But what he was most proud of was a species of short-hand of his own invention, wherewith he had carried off from the conventicles in England several volumes of sermons whole and entire; and these he designed for his nephew's stock in trade, when he should set up as preacher. But young Franklin had not been a year at school when his father perceived that his circumstances were quite inadequate to the expenses necessary to complete his son's education for the clerical profession. He accordingly removed him from the more learned seminary, and placed him under an humble teacher of reading and writing for another twelvemonth, preparatory to binding him to some handicraft trade.

APPRENTICESHIP.

When his term at school was expired, being then ten years of age, he was taken home to assist his father in

his business ; but he soon testified such repugnance to the cutting of wicks for candles, running errands, waiting in the shop, with other drudgery of the same nature, that, after a tedious and ill-borne trial of two years, his father became afraid of his running off to sea (for which he confesses to have had a predilection), as an elder brother had done, and resolved to put him to some other occupation. After much deliberation, therefore, he was sent on trial for a few days to his cousin (a son of Benjamin), who was a cutler ; but that relative being desirous of a larger apprentice-fee than his uncle could spare, he was recalled. His brother James, a short time previous to this period, had returned from England, whither he had been sent to learn the printing business, and set up a press and types on his own account at Boston. To him, therefore, after no little persuasion, Benjamin at last agreed to become apprentice, and he was indentured accordingly for the term of nine years ; that is, until he should reach the age of twenty-one.

The choice of this profession, as it turned out, was a lucky one ; and it was made after much careful and correct observation on the part of the parent. He had watched his son's increasing fondness for books, and thirst for information, and that, too, of a solid and instructive sort ; and he therefore judiciously resolved to place him in a favourable situation for gratifying this propensity in the youthful mind ; while he would, at the same time, be instructed in a profession by which he could always independently maintain himself, in whatever quarter his fortunes might lead him, within the bounds of the civilised world. Franklin thus speaks of his early and insatiable craving after knowledge :—

"From my earliest years I had been passionately fond of reading, and I laid out in books all the money I could procure. I was particularly pleased with accounts of voyages. My first acquisition was Bunyan's collection, in small separate volumes. These I afterwards sold, in order to buy an historical collection by R. Burton, which consisted of small cheap volumes, amounting in all to about forty or fifty. My father's little library was principally made up of books of practical and polemical theology. I read the greatest part of them. There was also among my father's books Plutarch's Lives, in which I read continually, and I still regard as advantageously employed the time devoted to them. I found, besides, a work of De Foe's, entitled *An Essay on Projects*, from which, perhaps, I derived impressions that have since influenced some of the principal events of my life." It seems to have been lucky for himself and mankind that the last-named author's most celebrated work, *Robinson Crusoe*, did not fall into his hands at this period.

By his assiduity Franklin soon attained great proficiency in his business, and became very serviceable to his brother. At the same time, he formed acquaintance with various booksellers' apprentices, by whose furtive assistance he was enabled to extend the sphere of his reading. This gratification, however, was for the most part enjoyed at the expense of his natural rest. "How often," says he, "has it happened to me to pass the greater part of the night in reading by my bedside, when the book had been lent me in the evening, and was to be returned the next morning, lest it might be missed or wanted !" His studious habits and intelligent conversation also attracted the notice of a wealthy merchant who was in the habit of coming about the office, who invited him to his house, and gave him the use of an excellent library.

It is a singular peculiarity of all minds of an active and aspiring character, that they uniformly endeavour to do whatever others have done, and from which they themselves have derived enjoyment or benefit. Franklin, from the delight he took in the perusal of books, at last bethought him of trying his own hand at composition ; and as has happened, we believe, with a great proportion of literary men of all ages, his first efforts were of a poetical nature. His brother having come to the knowledge of his attempts, encouraged him to

proceed, thinking such a talent might prove useful in the establishment. At the suggestion of the latter, therefore, he finished two ballads, which, after being printed, he was sent round the town to sell ; and one of them, the subject of which was a recent affecting shipwreck, had, he says, a prodigious run. But his father having heard of the circumstance, soon let down the pegs of the young poet's vanity, by analysing his verses before him in a most unmerciful style, and demonstrating, as Franklin says, what "wretched stuff they really were." This sharp lesson, which concluded with a warning that versifiers were almost uniformly beggars, effectually weaned him from his rhyming propensities.

Franklin immediately afterwards betook himself to the composition of prose, and the first opportunity of exercising his pen and his faculties in this way occurred in the following manner :—He had a young acquaintance of the name of Collins, who was like himself passionately fond of books, and with whom he had frequent and long arguments on various subjects. In narrating this circumstance, Franklin comments, in passing, on the dangerous consequences of acquiring a disputatious habit, as tending to generate acrimony and discord in society, and often hatred betwixt the best of friends. He dismisses the subject with the following singular enough observation :—"I have since remarked, that men of sense seldom fall into this error—lawyers, fellows of universities, and persons of every profession educated at Edinburgh, excepted!" But to proceed : Franklin and his companion having as usual got into an argument one day, which was maintained on both sides with equal pertinacity, they parted without bringing it to a termination ; and as they were to be separated for some time, an agreement was made that they should carry on their dispute by letter. This was accordingly done ; when, after the interchange of several epistles, the whole correspondence happened to fall into the hands of Franklin's father. After perusing it with much interest, his natural acuteness and good sense enabled him to point out to his son how inferior he was to his adversary in elegance of expression, arrangement, and perspicuity. Feeling the justice of his parent's remarks, he forthwith studied most anxiously to improve his style ; and the plan he adopted for this purpose is equally interesting and instructive.

"Amidst these resolves," he says, "an odd volume of the *Spectator* fell into my hands. This was a publication I had never seen. I bought the volume, and read it again and again. I was enchanted with it, thought the style excellent, and wished it were in my power to imitate it. With this view I selected some of the papers, made short summaries of the sense of each period, and put them for a few days aside. I then, without looking at the book, endeavoured to restore the essays to their due form, and to express each thought at length, as it was in the original, employing the most appropriate words that occurred to my mind. I afterwards compared my *Spectator* with the original. I perceived some faults, which I corrected ; but I found that I chiefly wanted a fund of words, if I may so express myself, and a facility of recollecting and employing them, which I thought I should by that time have acquired, had I continued to make verses. The continual need of words of the same meaning, but of different lengths, for the measure, and of different sounds for the rhyme, would have obliged me to seek for a variety of synonymes, and have rendered me master of them. From this belief, I took some of the tales of the *Spectator*, and turned them into verse ; and after a time, when I had sufficiently forgotten them, I again converted them into prose. Sometimes, also, I mingled my summaries together ; and, a few weeks afterwards, endeavoured to arrange them in the best order, before I attempted to form the periods and complete the essays. This I did with a view of acquiring method in the arrangement of my thoughts. On comparing afterwards my performance with the original, many faults were apparent, which I corrected ; but I had

sometimes the satisfaction to think, that, in certain particulars of little importance, I had been fortunate enough to improve the order of the thought or style; and this encouraged me to hope that I should succeed in time in writing decently in the English language, which was one of the greatest objects of my ambition."

But it was not only by such rigorous self-imposed tasks that this extraordinary man, even at so early an age, endeavoured to chasten his mind, and make every animal propensity subservient to his sense of duty. He also began to exercise those acts of personal self-denial which the heyday of youth, the season for animal enjoyment, feels as the most intolerable of all restrictions. Having met with a work recommending a vegetable diet, he determined to adopt it. Finding, after some days' trial, that he was ridiculed by his fellow-boarders for his singularity, he proposed to his brother to take the half of what was now paid by that relative for his board, and therewith to maintain himself. No objection was, of course, made to such an arrangement; and he soon found that of what he received he was able to save one-half. "This," says he, "was a new fund for the purchase of books, and other advantages resulted to me from the plan. When my brother and his workmen left the printing-house to go to dinner, I remained behind; and dispatching my frugal meal, which frequently consisted of a biscuit only, or a slice of bread and a bunch of raisins, or a bun from the pastry-cook's, with a glass of water, I had the rest of the time till their return for study; and my progress therein was proportioned to that clearness of ideas and quickness of conception which are the fruits of temperance in eating and drinking."

Another remarkable instance of the resolute way in which he set about making himself master of whatever acquirement he found more immediately necessary to him at the moment, is the following:—Having been put to the blush one day for his ignorance in the art of calculation, which he had twice failed to learn while at school, he procured a copy of Cocker's Arithmetic, and went through it all, making himself completely master of it before turning his mind to any thing else! He soon after, also, gained some little acquaintance with geometry, by perusing a work on navigation. He mentions, likewise, his reading about this time Locke's Essay on the Understanding, and the Art of Thinking, by Messrs du Port Royal. Having found, in some essay on rhetoric and logic, a model of disputation after the manner of Socrates, which consists in drawing on your opponent, by insidious questions, into making admissions which militate against himself, he became excessively fond of it, he says, and practised it for some years with great success, but ultimately abandoned it, perceiving that it could be made as available to the cause of wrong as that of right, while the prime end of all argument was to convince or inform.

About three years after Franklin went to his apprenticeship, that is to say, in 1721, his brother began to print a newspaper, the second that was established in America, which he called the New England Courant: the one previously established was the Boston News Letter. The new publication brought the most of the *literati* of Boston about the printing-office, many of whom were contributors; and Franklin frequently overheard them conversing about the various articles that appeared in its columns, and the approbation with which particular ones were received. He became ambitious to participate in this sort of fame; and having written out a paper, in a disguised hand, he slipped it under the door of the printing-office, where it was found next morning, and submitted, as usual, to the critics when they assembled. "They read it," he says; "commented on it in my hearing; and I had the exquisite pleasure to find that it met with their approbation; and that in the various conjectures they made respecting the author, no one was mentioned who did not enjoy a high reputation in the country for talent and genius. I now supposed myself fortunate in my judges, and began to suspect that they were not such excellent

writers as I had hitherto supposed them. Be this as it may, encouraged by this little adventure, I wrote and sent to press, in the same way, many other pieces which were equally approved—keeping the secret till my slender stock of information and knowledge for such performances was pretty completely exhausted." He then discovered himself, and had the satisfaction of finding he was treated with much more respect by his brother and his friends than heretofore.

The two brothers, however, lived together on very disagreeable terms, in consequence of the hasty and overbearing temper of the elder; and Benjamin anxiously longed for an opportunity of separating from him. This at last occurred. His brother was apprehended and imprisoned for some political article which offended the local government, and upon his liberation was prohibited from ever printing his newspaper again. It was therefore determined that it should be published in Benjamin's name, who had managed it during his brother's confinement with great spirit and ability. To avoid having it said that the elder brother was only screening himself behind one of his apprentices, Benjamin's indenture was delivered up to him discharged, and private indentures entered into for the remainder of his time. This underhand arrangement was proceeded in for several months, the paper continuing to be printed in Benjamin's name; but his brother having one day again broken out into one of his violent fits of passion, and struck him, he availed himself of his discharged indentures, well knowing that the others would never be produced against him, and gave up his employment. Franklin afterwards regretted his having taken so unfair an advantage of his brother's situation, and regarded it as one of the first *errata* of his life. His brother felt so exasperated on the occasion, that he went round all the printing-houses, and represented Benjamin in such a light that they all refused his services.

PROCEEDS TO PHILADELPHIA.

Finding he could get no employment at Boston, as well as that he was regarded with dislike by the government, he resolved to proceed to New York, the nearest town in which there was a printing-office. To raise sufficient funds for this purpose, he sold part of his library; and having eluded the vigilance of his parents, who were opposed to his intention, he secretly got on board of a vessel, and landed at New York on the third day after sailing.

Thus, at the age of seventeen, Franklin found himself three hundred miles from his native place, from which he was in some sort a runaway, without a friend, or recommendation to any one, and with very little money in his pocket. To complete his dilemma, he found, on applying, that the only printer then in the town could give him no employment. That person, however, recommended him to go to Philadelphia, where he had a son, who, he thought, would give him work; and he accordingly set off for that place. His journey was a most disastrous one both by water and land, and he frequently regretted leaving home so rashly. He reached his destination at last, however, and in a plight which certainly did not bode over-auspiciously for his future fortunes. His own graphic description of his condition and appearance, on his first entrance into Philadelphia, is at once interesting and amusing:—

"I have entered into the particulars of my voyage, and shall in like manner describe my first entrance into this place, that you may be able to compare beginnings so unlikely with the figure I have since made. I was in my working dress, my best clothes being to come by sea. I was covered with dirt; my pockets were filled with shirts and stockings; I was unacquainted with a single soul in the place, and knew not where to seek a lodging. Fatigued with walking, rowing, and having passed the night without sleep, I was extremely hungry, and all my money consisted of a Dutch dollar, and about a shilling's worth of coppers, which I gave to the boatmen for my passage. At first they refused

it, because I had rowed, but I insisted on them taking it. A man is sometimes more generous when he has little than when he has much money, probably because he is, in the first place, desirous of concealing his poverty.

I walked towards the top of the street, looking eagerly on both sides, till I came to Market Street, where I met a child with a loaf of bread. I inquired where he had bought it, and went straight to the baker's shop which he pointed out to me. I asked for some biscuits, expecting to find such as we had at Boston; but they made, it seems, none of that sort at Philadelphia. I then asked for a threepenny loaf; they made no loaves of that price. I then desired him to let me have threepence worth of bread, of some kind or other. He gave me three large rolls. I was surprised at receiving so much. I took them, however, and having no room in my pockets, I walked on, with a roll under each arm, eating the third. In this manner I went through Market Street to Fourth Street, and passed the house of Mr Read, the father of my future wife. She was standing at the door, observed me, and thought with reason that I made a very singular and grotesque appearance. I then turned the corner, and went through Chestnut Street, eating my roll all the way; and, having made this round, I found myself again on Market Street wharf, near the boat in which I arrived. I stepped into it to take a draught of the river water; and finding myself satisfied with my first roll, I gave the other two to a woman and her child who had come down the river with us in the boat, and was waiting to continue her journey. Thus refreshed, I regained the street, which was now full of well-dressed people all going the same way. I joined them, and was thus led to a Quakers' meeting-house, near the market-place. I sat down with the rest, and, after looking round me for some time, hearing nothing said, and being drowsy from my last night's labour and want of rest, I fell into a sound sleep. In this state I continued till the assembly dispersed, when one of the congregation had the goodness to wake me. This was consequently the first house I entered, or in which I slept, in Philadelphia."

Having with some difficulty procured a lodging for the night, he next morning waited on Mr Bradford, the printer to whom he had been directed. That individual said he had no work for him at present, but directed him to a brother in trade of the name of Keimer, who, upon application, made him the same answer; but, after considering a little, set him to put an old press to rights, being the only one indeed he possessed; and in a few days gave him regular work. Upon this, Franklin took a lodging in the house of Mr Read, his future father-in-law.

Franklin had been some months at Philadelphia, without either writing to or hearing from home, and, as he says, trying to forget Boston as much as possible, when a brother-in-law of his, a master of a vessel, having accidentally heard where he was, wrote to him, pressing his return home in the most urgent terms. Franklin's reply, declining compliance with the request, happened to reach his brother-in-law when the latter was in the company of Sir William Keith, governor of the province; and the composition and penmanship struck him as so much superior to the ordinary style of letter-writing, that he showed it to his excellency. The governor was no less pleased with it, and expressed the utmost surprise when told the age of the writer. He observed, that he must be a young man of promising talents, and said that if he would set up business on his own account at Philadelphia, he would procure him the printing of all the public papers, and do him every other service in his power. Franklin heard nothing of this from his brother-in-law at the time; but one day, while he and Keimer were at work in the office, they observed through the window the governor and another gentleman (who proved to be Colonel French of Newcastle, in the province of Delaware), finely dressed, cross the street, and come directly for the office, where they knocked at the door. Keimer ran down, in high expectation of this being a visit to

himself; "but the governor (says Franklin) inquired for me, came up stairs, and with a politeness to which I had not at all been accustomed, paid me many compliments, desired to be acquainted with me, obligingly reproached me for not having made myself known to him on my arrival in town, and wished me to accompany him to a tavern, where he and Colonel French were going to taste some excellent Madeira wine! I was, I confess, somewhat surprised, and Keimer was thunder-struck. I went, however, with the governor and Colonel French to a tavern at the corner of Third Street, where, while we were drinking the Madeira, he proposed to me to establish a printing-house. He set forth the probabilities of success, and himself and Colonel French assured me that I should have their protection and influence in obtaining the printing of the public papers for both governments; and as I appeared to doubt whether my father would assist me in this enterprise, Sir William said that he would give me a letter to him, in which he would recommend the advantages of the scheme in a light which he had no doubt would determine him to agree to do so. It was thus concluded that I should return to Boston by the first vessel, with the letter of recommendation from the governor to my father. Meanwhile, the project was to be kept secret, and I continued to work to Keimer as before. The governor subsequently sent for me every now and then to dine with him. I considered this as a very great honour; and I was the more sensible of it, as he conversed with me in the most affable, friendly, and familiar manner imaginable."

In pursuance of the above arrangement, Franklin set out on his return homewards, in the end of April 1724, having been absent about seven months, during which time his parents and relations had heard nothing of him whatever, his brother-in-law never having written to inform them where he was. All the family, with the exception of his brother James, were delighted to see him; and not the less so, perhaps, that he was appalled in a complete new suit of clothes, had an excellent silver watch, and about five pounds sterling in his pocket. His father was exceedingly surprised when informed of the object of his visit, and still more at the contents of Governor Keith's epistle. After long deliberation, he came to the resolution of refusing compliance with the request, on account of his son being too young to undertake the management of such a speculation; adding, that he thought the governor a man of little discretion in proposing it. He promised, however, when his son should attain his twenty-first year, that he would supply him with what money he required to set him up in business, praising him highly, at the same time, for his industry and good conduct. Franklin, accordingly, was necessitated to return to Philadelphia with the news of his bad success, but left Boston on this occasion accompanied by the blessings of his parents. When he arrived at Philadelphia, he immediately waited upon the governor, and communicated the result of his journey. Sir William observed that his father was "too prudent;" but added, "since he will not do it, I will do it myself." It was ultimately arranged, therefore, that Franklin should proceed personally to London, to purchase every thing necessary for the proposed establishment, for the expense of which the governor promised him a letter of credit to the extent of £100, with recommendations to various people of influence.

SAILS FOR ENGLAND.

It had been arranged that Franklin was to go to England in the regular packet-ship; and as the time of her sailing drew near, he became importunate for the governor's letters of credit and recommendation, but the latter always put him off under various pretences. At last, when the vessel was on the point of departing, he was sent on board, under the assurance that Colonel French would bring the letters to him immediately. That gentleman accordingly came on board with a packet of dispatches tied together, which were put into the captain's bag, and Franklin was informed that those

intended for him were tied up with the rest, and would be delivered to him before landing in England. When they arrived in the Thames, accordingly, the captain allowed him to search the bag, but Franklin could find no letters directed either to himself or addressed as to his care; but he selected six or seven, which, from the directions on them, he conceived to be those intended for his service. One of these was to the king's printer, and Franklin accordingly waited upon that gentleman with it; but the latter had no sooner opened it, than he exclaimed, "Oh, this is from Riddlesden!—(a well-known rascally attorney at Philadelphia); I have lately discovered him to be an arrant knave, and wish to have nothing to do either with him or his letters." So saying, he turned on his heel, and resumed his occupation. In short, it turned out that none of the letters were from the governor; and he soon learned from a gentleman of the name of Denham, who had been a fellow-passenger with him, and to whom he explained his awkward situation, that the governor was a complete cheat, deceiving people, from vanity and a love of self-consequence, with promises which he neither intended nor was able to fulfil; and laughed at the idea of a man giving a letter of credit for £100 who had no credit for himself.

Franklin's situation was now even more desolate than when set ashore, ragged, hungry, and almost penniless, at Philadelphia, little more than a twelvemonth before. But the heart at eighteen is not naturally inclined to despond, and never was one less so than Franklin's. He immediately applied for and obtained employment in the office of the celebrated Mr Palmer. Amongst other works on which he was set to work here, was a second edition of Wollaston's Religion of Nature. Conceiving some of the positions assumed in it to be weak or erroneous, he composed and published a small metaphysical treatise in refutation of them. This pamphlet acquired him considerable credit with his master as a man of talent; but that gentleman reproached, with the utmost abhorrence, the doctrines maintained in his publication, which, truth compels us to say, were completely irreligious, so far as regarded the Christian faith, or any other acknowledged system of belief. Free-thinking, however, was then in fashion among the higher and more learned classes, and his pamphlet procured him the countenance of various eminent individuals; amongst the rest, of Dr Mandeville, author of the Fable of the Bees, and Dr Pemberton, Sir Isaac Newton's friend. He was likewise waited upon by Sir Hans Sloane, who had been informed of his bringing some curiosities with him from America; amongst others, a purse of asbestos—a natural substance which resists the action of fire, and then very little known—for which he paid Franklin a high price. From Mr Palmer's office he removed to Mr Watt's, for the consideration of a higher wage. Here he gave a striking proof of that resolute adherence to temperance, industry, and frugality, which were amongst the leading features of his character. Whilst Mr Watt's other workmen spent generally five or six shillings a-week on beer, which was brought into the office to them during the day, he drank nothing but water; and they were surprised to see that he was much stronger than any of them, while he himself had the additional comfort and satisfaction of being always clear-headed. At first they ridiculed his abstinence, and conferred upon him the soubriquet of the *American Aquatic*; but as his character rose amongst them, his example, he says, "prevailed with several of them to renounce their abominable breakfast of bread and cheese, with beer; and they procured, like me, from a neighbouring house, a good basin of warm gruel, in which was a small slice of butter, with toasted bread and nutmeg. This was a much better breakfast, which did not cost more than a pint of beer, namely, three halfpence, and at the same time preserved the head clearer." His assiduous application to business, at the same time, together with remarkable quickness in composing (setting up the types), recommended him to his employer, and procured him all the most urgent and

best-paid work: so that, with his frugal mode of living, he quickly laid past money.

RETURNS TO AMERICA.

After having been about eighteen months in London, much to his advantage in every respect—for, besides becoming more proficient in his business, he had stuck to his books as sedulously as ever, even although he frequently went to the play, made little pleasure excursions, and mingled a good deal in society—he was about to set out on a tour through Europe, with a young intelligent fellow-workman (designing to maintain themselves during their pilgrimage by means of their calling), when he accidentally met with Mr Denham, before noticed as being his fellow-passenger from America. That gentleman was on the eve of returning to Philadelphia, to open a merchant's store, and offered Franklin the situation of his clerk, with a salary of £50 per annum. This sum was less than he was making as a compositor; but an anxious desire to revisit his native country induced him to accept of it. They set sail accordingly—Franklin now supposing he had relinquished the composing-stick for ever—and arrived at Philadelphia on the 11th of October 1726. Franklin had just entered his twenty-first year at this time; and he mentions having drawn up for himself in writing, during the voyage, a plan for the regulation of his future conduct. This interesting document was afterwards unfortunately lost; but he tells us himself that he pretty faithfully adhered to the rules thus early laid down, even into old age. Upon his arrival, he found that his old acquaintance, the governor, had been supplanted in his office, and was held in general contempt. They met several times, but no allusion was ever made by Franklin to the disgraceful imposture the other had practised on him.

Franklin's new employer had only been in business for a few months, when both were seized at the same time with a violent disorder, which carried off the master in a few days, and brought the clerk to the brink of the grave. On his recovery, being thus once more left destitute, he was fain to accept employment as a printer from his old master Keimer, who was now somewhat better off in the world, but still utterly ignorant of his profession. The whole charge of the office, with that of instructing four or five ignorant apprentices, devolved on Franklin. "I also," says he, "upon occasion, engraved various ornaments, made ink, gave an eye to the shop—in short, I was, in every respect, the *factotum*." But he likewise, at this time, gave another remarkable instance of his versatile ingenuity.

"Our press," says he, "was frequently in want of the necessary quantity of letter, and there was no such trade as that of letter-founder in America. I had seen the practice of this art at the house of James, in London, but had at the time paid it very little attention. I, however, contrived to fabricate a mould. I made use of such letters as we had for punches, founded new letters of lead in matrices of clay; and thus supplied, in a tolerable manner, the wants that were most pressing." Franklin's inventive mind would seem here to have obtained a distant glimpse of the principle of *stereotyping*, which has since been carried to such a height of usefulness and perfection, as exemplified in the various publications of the editors of this miscellany.

Keimer having engaged Franklin solely with the view of having his apprentices so far initiated in the art as that he could dispense with their instructor's services, took the first occasion to quarrel with him when he thought he had sufficiently attained his object. Upon their separation, one of Keimer's apprentices, named Meredith, who, like all the others, had conceived a great veneration for Franklin, proposed that they should enter into partnership together—Meredith's friends undertaking to furnish the capital necessary for purchasing the materials, &c. This offer was too advantageous to be refused, and types, press, &c., were forthwith commissioned from London; but while preparing to put their plan into execution, Franklin was induced,

during the interval, to return again to Keimer, at the urgent solicitation of the latter. The motive for this humble entreaty was that individual's having taken a contract for the printing of some paper-money for the state of New Jersey, requiring a variety of new cuts and types, which he knew well nobody in that place but Franklin could supply. This also presents us with a very striking instance of Franklin's remarkable gift of invention.

"To execute the order," says he, "I constructed a copperplate printing-press—the first that had been seen in the country. I engraved various ornaments and vignettes for the bills, and we repaired to Burlington together, where I executed the whole to the general satisfaction, and he (Keimer) received a sum of money for this work which enabled him to keep his head above water for a considerable time longer."

At Burlington, Franklin formed acquaintance with all the principal personages of the province, who were attracted by his superior abilities and intelligence. Amongst these was the inspector-general, Isaac Decon, "who," says Franklin, "was a shrewd and subtle old man. He told me that his first employment had been that of carrying clay to the brickmakers; that he did not learn to write till he was somewhat advanced in life; that he was afterwards employed as underling to a surveyor, who taught him his trade; and that, by industry, he had at last acquired a competent fortune. 'I foresee,' said he, 'that you will soon supplant this man (speaking of Keimer), and get a fortune in the business at Philadelphia.' He was wholly ignorant at the time of my intention of establishing myself there, or any where else."

ENTERS INTO BUSINESS.

Franklin had scarcely returned from Burlington, when the types commissioned for himself and Meredith, from London, arrived; and having settled matters with Keimer, the partners immediately took a house, and commenced business. They were in the act of opening up their packages, when a countryman came in to have a job done; and as all their cash had been expended in their various purchases, "this countryman's five shillings," says Franklin, "being our first fruits, and coming so seasonably, gave me more pleasure than any crown I have since earned." A number of young men having, during the preceding year, formed themselves, at Franklin's suggestion, into a weekly club for the purpose of mutual improvement, they were so well pleased with the beneficial results they experienced from their meetings, that, when the originator of their society set up in business, every one exerted himself more than another to procure him employment. One of them obtained from the Quakers the printing of forty sheets of a history of that sect, then preparing at the expense of the body. "Upon these," says Franklin, "we worked exceeding hard, for the price was very low. It was in folio, upon *pro patria* paper, and in the *pica* letter, with heavy notes in the smallest type. I composed a sheet a-day, and Meredith put it to press. It was frequently eleven o'clock at night, sometimes later, before I had finished my distribution for the next day's task; for the other little jobs that came in kept us back in this work; but I was so determined to compose a sheet a-day, that one evening, when my form was imposed, and my day's work, as I thought at an end, an accident broke the form, and deranged two complete folio pages. I immediately distributed and composed them anew before I went to bed." This unwearied industry, which soon became known, acquired Franklin great reputation and credit amongst his townsmen, and business began rapidly to flow in upon them.

STARTS A NEWSPAPER.

The establishment and management of a newspaper seems to have all along been a favourite project with Franklin; probably because, from his former experience in it, and the consciousness of his powers of writing, he felt himself so well adapted for the task. The

partners soon found themselves in circumstances to enable them to make the trial; but Franklin having incautiously divulged their intention to a third person, that individual informed their old master Keimer of the fact, who immediately took steps to anticipate them, and issued a prospectus of a paper of his own. The manner in which Franklin met and defeated this treachery is exceedingly characteristic. There was another paper published in Philadelphia by Mr Bradford, which had been in existence for some years, but was such a miserable affair, that it only preserved its vitality because no other arose to knock it on the head. In order to keep down Keimer's publication, however, Franklin saw the policy of supporting the old one until prepared to start his own. He thereupon set about writing a series of amusing articles for it, which the publisher, Bradford, was of course very glad to insert. "By this means," says Franklin, "the attention of the public was kept fixed on that paper, and Keimer's proposals, which we burlesqued and ridiculed, were disregarded. He began his paper, however; and, after continuing it for nine months, having at most not more than ninety subscribers, he offered it to me for a mere trifle. I had for some time been prepared for it; I therefore instantly took it upon myself, and in a few years it proved very profitable to me." In fact, it obtained notoriety and applause at the very first number, in consequence of some observations therein by Franklin, on an important colonial question; and various members of Assembly exerted themselves so well in his behalf, that the printing of the House was speedily transferred from Bradford to his two young rivals. In the management of his newspaper, Franklin pursued a system of unflinching integrity. He steadfastly refused to give admission into his columns of any article containing personal abuse of particular individuals. Whenever he was requested to publish any thing of this sort, his answer was, that he would print the piece by itself, and give the author as many copies for his own distribution as he wished. He very wisely considered that his subscribers expected him to furnish them with useful and entertaining information, and not with personal slander or private discussions with which they had no concern.

COMMENCES BUSINESS BY HIMSELF.

Luckily for Franklin, almost at the commencement of the newspaper, an opportunity occurred of getting rid of his partner Meredith, who had become an idle drunken fellow, and had all along been of comparatively little use in the concern. Meredith's father failed to implement the bargain for advancing the necessary capital to pay the demands of the paper-merchant, and other expenses necessarily attending their speculation, when they became due. A suit was accordingly instituted against the partners; and as Meredith's father declared his inability to pay the amount of the claims upon them, the son offered to relinquish the whole concern into Franklin's hands, on condition that the latter would take upon him the debts of the company, repay his father what he had already advanced, settle his own little personal debts, and give him thirty pounds and a new saddle! By the kindness of two friends, who, unknown to each other, came forward simultaneously and unasked to his assistance, Franklin was enabled to accept the offer. The agreement was carried into effect, and thus do we find this extraordinary man, at the age of twenty-four, and in the place where he had arrived penniless only seven years before, settled down in business, with a thriving trade; proprietor of an extensively circulated newspaper, and a firmly established reputation of no ordinary kind. All this success, however, the result of his own good conduct, perseverance, and frugality, had no undue effect on his well-regulated mind, or could induce him to assume those airs of arrogant superiority and pretension, which have but too frequently blemished the character of those who have praiseworthily achieved their own elevation in society. On the contrary, he dressed more plainly, and deputed himself more humbly, than ever; and to show that he

was not above his business, he sometimes wheeled home on a barrow, with his own hands, the paper which he purchased at the stores.

Soon after getting the whole printing and newspaper concern into his hands, there was an outcry among the people for a new emission of paper-money. Franklin took up the cause, and by his arguments in a pamphlet which he published on the subject, contributed so greatly to the success of the proposal, and obtained himself so much popularity, that upon its being resolved to issue the notes, Franklin was selected to print them. He then opened a stationer's shop, and from his success in business, began gradually to pay off his debts. Meanwhile, his old master Keimer went fast to ruin, and, with the exception of old Mr Bradford, who was rich and did not care for business, he was the only printer in the place. He shortly afterwards married Miss Read, the lady named in a former part of this memoir. Franklin's behaviour to this young lady had not been altogether blameless. Previous to his sailing for England, he had exchanged pledges of affection with her; yet, all the while he was away, he only sent her one letter. Her friends and herself concluding that he either never meant to return, or that he wished to drop connexion with her, she was induced to accept the hand of another suitor, and on his return to America Franklin found her married—an event that seems to have given him extremely little uneasiness. The lady's husband proved a great rogue, deserted her, and it was subsequently ascertained that he had still a former wife living. After being established in business, and rising in the world, the intimacy between Franklin and her family was renewed, and it was not long ere, despite her dubious situation, they hazarded a fulfilment of their early vows. The lady was about Franklin's own age, and proved, according to his own testimony, "an honour and a blessing" to him.

In 1731, Franklin drew up proposals for a public subscription library at Philadelphia, being the first project of the sort that had been started in America. Fifty persons at first subscribed forty shillings each, and agreed to pay ten shillings annually; and the establishment was put under such judicious rules of management, that in the course of ten years it became so valuable and important as to induce the proprietors to get themselves incorporated by royal charter. This library afforded its founder facilities of improvement of which he did not fail to avail himself, setting apart, as he tells us, an hour or two every day for study, which was the only amusement he allowed himself. Several other companies were formed in the city in imitation of it, and the whole were finally united in one institution. A taste for reading was thus spread around, and libraries were formed throughout Pennsylvania.

Franklin was much gratified by the success of his scheme, and continued by his example to encourage habits of industry in the young, and to raise a taste for literary and other rational recreations. We now find him, at the early age of twenty-five or twenty-six, fairly embarked in life as a tradesman, citizen, and a lover of literary and scientific pursuits. His first consideration was scrupulous attention to business and to his family. He took care, he says, not only to be *really* industrious and frugal, but also to avoid every appearance to the contrary—was plainly dressed, and was never seen in any place of amusement: never went a-fishing or hunting; his only relaxation being in a game at chess, of which he was very fond. He devoted the greater part of his leisure time to self-examination and improvement. On instituting a rigorous examination into his conduct and character, he found that he possessed many faults, which he resolved upon amending: he even conceived the bold idea of seeking to attain *moral perfection*. With the view of carrying this project into execution, he fell upon the device of methodising his time during the twenty-four hours of every day, and of laying down certain rules by which he should regulate his conduct and sentiments. He rose at 5 in the morning; the next three hours he appropri-

ated to devotional exercise, study, cleaning of the person, and breakfast. From 8 till 12 he was at work. From 12 till 2 he read, did any desultory duties, and dined. From 2 till 5 he was again at work. From 6 till 10, he devoted to reading, conversation, intercourse with his family, and supper; and from 10 till 4 or 5 in the morning, to sleep; after which he arose and pursued the same routine as before. We thus see that early rising was a leading feature in his habits of life, and to this alone he doubtless owed much of his success.

Franklin's arrangement of his time was less remarkable than his plan of self-examination. We have said that he established certain rules for the regulation of his conduct. These were thirteen in number, and were called by him virtues or precepts to be kept in remembrance: they are thus summed up:—Temperance; silence, or abstaining from frivolous talking; order; resolution, or determination to perform promises and duties; frugality; industry; sincerity, or avoiding of all deceit; justice, or the wronging of no one; moderation; cleanliness; tranquillity of mind; chastity; and humility, in which was included an endeavour to imitate Christ, and also Socrates. It is mentioned by Franklin, that it required a constant care to avoid infringing upon these precepts, and that at length, to assist himself, he prepared a book to serve as a journal of his conduct and thoughts, in which he took pains to mark every error he committed. By this means he was able to observe how he advanced in virtue, and how far he abstained from error: it was his anxious wish to see the tables in his book free from any markings or indications of imperfection of character. To this journal of his conduct he attached certain mottoes; one of which was a verse from the Proverbs of Solomon, in which wisdom is eulogised:—"Length of days is in her right hand, and in her left riches and honour. Her ways are ways of pleasantness, and all her paths are peace." Another of his mottoes was in the form of a pious aspiration or prayer, in which he implored the divine blessing on his labours, and an increase of that wisdom which was most beneficial to him. One of his favourite passages, which he occasionally repeated, was the beautiful address to the Deity in Thomson's poem on the Seasons:—

"Father of light and life, thou God supreme!
Oh teach me what is good; teach me thyself!
Save me from folly, vanity, and vice,
From every low pursuit; fill my soul
With knowledge, conscious peace, and virtue pure,
Sacred, substantial, never-fading bliss!"

He tells us that the most troublesome part of his prescribed task of self-regulation, was the obligation to preserve order in his line of duties—being most likely liable to distraction by trifling circumstances constantly interfering to mar his project. Nevertheless, he persevered, forced himself to be methodic, and was thus able to proceed with studies tending greatly to his mental improvement, and his increase in useful knowledge.

Of Franklin's intercourse with his family little has been made known, though it is ascertained, by a few scattered hints in his writings, that he was an affectionate husband and father, and placed much of his happiness in home. In his household affairs the most exact economy prevailed, and, for several years after his marriage, his breakfast consisted simply of bread and milk, which he ate from a twopenny earthenware porringer with a pewter spoon. Fortunately, his wife was as much disposed to be industrious as he was; she assisted him in his business, folded the sheets of books which he printed, kept his shop, and executed other humble but useful duties. By following this industrious and economical plan of living, they gradually accumulated wealth, and were enabled to possess comforts and luxuries which were at first beyond their reach. Still, Franklin was not puffed up by prosperity, but continued to live in a style of simplicity agreeable to the notions he had formed at the outset of his career.

In conducting his business, he happily united the oc-

cupation of a printer with the profession of an author, and thus became the publisher of his own literary productions. No large work, however, was given by him to the world. His writings were chiefly of a minor character, such as detached pamphlets on subjects of local import, and short essays; and he did not, as it appears, write much that has been thought worthy of republication in a succeeding age. His newspaper was the *Pennsylvania Gazette*, which had been started by Keimer in 1728, and which, after about a twelvemonth's mismanagement, had come into the possession of Franklin and Hugh Meredith. By Franklin's ingenuity, the paper rose in general estimation.

Besides editing his newspaper, he conducted and published an almanack, which he began in 1732, and continued for a period of twenty-five years. This almanack bore the feigned name, Richard Saunders, and hence acquired the title of *Poor Richard's Almanack*, by which it became extensively known. The leading feature of the work consisted in an array of concise maxims and apothegms of an economical character, distributed here and there throughout the calendar, wherever space was left betwixt the names of the holidays. When *Poor Richard's Almanack* was brought to a close, a considerable number of the maxims were collected in an *Address to the Reader*, in the last number, and entitled *The Way to Wealth*. This admirable digest has been since translated into various languages, and is now widely known. We here subjoin a copy:—

THE WAY TO WEALTH.

I stopped my horse lately where a great number of people were collected at an auction of merchants' goods. The hour of sale not being come, they were conversing on the badness of the times; and one of the company called to a plain, clean old man, with white locks, "Pray, Father Abraham, what think ye of the times? Won't these heavy taxes quite ruin the country? How shall we ever be able to pay them? What would you advise us to?" Father Abraham stood up, and replied, "If you have my advice, I'll give it to you in short: 'for a word to the wise is enough: and many words won't fill a bushel,' as poor Richard says." They joined in desiring him to speak his mind; and, gathering round him, he proceeded as follows:—

"Friends (says he) and neighbours, the taxes are indeed very heavy; and if those laid on by the government were the only ones we had to pay, we might more easily discharge them: but we have many others, and much more grievous to some of us. We are taxed twice as much by our idleness, three times as much by our pride, and four times as much by our folly; and from these taxes the commissioners cannot ease or deliver us, by allowing an abatement. However, let us hearken to good advice, and something may be done for us: 'God helps them that help themselves,' as poor Richard says in his Almanack.

It would be thought a hard government that should tax its people one-tenth part of their time, to be employed in its service; but idleness taxes many of us much more, if we reckon all that is spent in absolute sloth, or doing of nothing, with that which is spent in idle employments, or amusements that amount to nothing. Sloth, by bringing on diseases, absolutely shortens life. 'Sloth, like rust, consumes faster than labour wears; while the key often used is always bright,' as poor Richard says. 'But dost thou love life? then do not squander time, for that's the stuff life is made of,' as poor Richard says. How much more than is necessary do we spend in sleep! forgetting that 'the sleeping fox catches no poultry, and that there will be sleeping enough in the grave,' as poor Richard says. 'If time be of all things the most precious, wasting time must be (as poor Richard says) the greatest prodigality; since, as he elsewhere tells us, 'Lost time is never found again; and what we call time enough, always proves little enough.' Let us then up and be doing, and doing to the purpose: so by diligence shall

we do more with less perplexity. 'Sloth makes all things difficult, but industry all easy,' as poor Richard says; and 'He that riseth late must trot all day, and shall scarce overtake his business at night; while laziness travels so slowly, that poverty soon overtakes him,' as we read in poor Richard; who adds, 'Drive thy business, let not that drive thee,' and,

'Early to bed, and early to rise,
Makes a man healthy, wealthy, and wise.'

So what signifies wishing and hoping for better times? We make these times better if we bestir ourselves. 'Industry needs not wish,' as poor Richard says; 'He that lives upon hope will die fasting.' 'There are no gains without pains; then help, hands, for I have no lands: or if I have, they are smartly taxed,' and (as poor Richard likewise observes) 'He that hath a trade hath an estate, and he that hath a calling hath an office of profit and honour; but then the trade must be worked at, and the calling well followed, or neither the estate nor the office will enable us to pay our taxes. If we are industrious, we shall never starve; for as poor Richard says, 'At the working-man's house hunger looks in, but dares not enter.' Nor will the bailiff or the constable enter; for 'Industry pays debts, but despair increaseth them,' says poor Richard. What though you have found no treasure, nor has any rich relation left you a legacy? 'Diligence is the mother of good luck,' as poor Richard says: and 'God gives all things to industry: then plough deep while sluggards sleep, and you will have corn to sell and to keep,' says poor Dick. Work while it is called to-day; for you know not how much you may be hindered to-morrow; which makes poor Richard say, 'One to-day is worth two to-morrows,' and, further, 'Have you somewhat to do to-morrow, do it to-day.' 'If you were a servant, would you not be ashamed that a good master should catch you idle? Are you, then, your own master? be ashamed to catch yourself idle,' as poor Dick says. When there is so much to be done for yourself, your family, and your gracious king, be up by peep of day: 'Let not the sun look down, and say, Inglorious here he lies!' Handle your tools without mittens; remember that 'The cat in gloves catches no mice,' as poor Richard says. It is true, there is much to be done, and perhaps you are weak-handed; but stick to it steadily, and you will see great effects; for continual dropping wears away stones, and by diligence and patience the mouse ate into the cable; and 'light strokes fell great oaks,' as poor Richard says in his Almanack, the year I cannot just now remember.

Methinks I hear some of you say, 'Must a man afford himself no leisure?'—I will tell thee, my friend, what poor Richard says. 'Employ thy time well, if thou meanest to gain leisure; and since thou art not sure of a minute, throw not away an hour.' Leisure is time for doing something useful; this leisure the diligent man will obtain, but the lazy man never; so that, as poor Richard says, 'A life of leisure and a life of laziness are two things.' Do you imagine that sloth will afford you more comfort than labour? No; for, as poor Richard says, 'Troubles spring from idleness, and grievous toils from needless ease: many without labour would live by their own wits only; but they break for want of stock.' Whereas industry gives comfort, and plenty, and respect. 'Fly pleasures, and they'll follow you; the diligent spinner has a large shift; and now I have a sheep and a cow, every body bids me good-morrow,' all which is well said by poor Richard.

But with our industry, we must likewise be steady, and settled, and careful, and oversee our own affairs with our own eyes, and not trust too much to others; for, as poor Richard says,

'I never saw an oft-removed tree,
Nor yet an oft-removed family,
That thrive so well as one that settled be.'

And again, 'Three removes are as bad as a fire,' and again, 'Keep thy shop, and thy shop will keep thee,' and again, 'If you would have your business done, go; if not, send.' And again,

'He that by the plough would thrive,
Himself must either hold or drive.'

And again, 'The eye of the master will do more work than both his hands;' and again, 'Want of care does us more damage than want of knowledge;' and again, 'Not to oversee workmen is to leave them your purse open.' Trusting too much to others' care is the ruin of many; for, as the Almanac says, 'In the affairs of the world, men are saved not by faith, but by the want of it; but a man's own care is profitable; for,' saith poor Dick, 'Learning is to the studious, and riches to the careful, as well as power to the bold, and heaven to the virtuous.' And, further, 'If you would have a faithful servant, and one that you like, serve yourself.' And again, he adviseth to circumspection and care, even in the smallest matters, because sometimes 'A little neglect may breed great mischief;' adding, 'For want of a nail the shoe was lost; for want of a shoe the horse was lost; and for want of a horse the rider was lost;' being overtaken and slain by the enemy, all for want of care about a horse-shoe nail.

So much for industry, my friends, and attention to one's own business; but to these we must add frugality, if we would make our industry more certainly successful. A man may, if he knows not how to save as he gets, 'keep his nose all his life to the grindstone, and die not worth a groat at last.' 'A fat kitchen makes a lean will,' as poor Richard says; and,

'Many estates are spent in the getting;
Since women for tea forsook spinning and knitting,
And men for punch forsook heaving and splitting.'

'If you would be wealthy (says he in another Almanac), think of saving, as well as of getting: the Indies have not made Spain rich, because her outgoes are greater than her incomes.'

Away, then, with your expensive follies, and you will not have much cause to complain of hard times, heavy taxes, and chargeable families; for, as poor Dick says,

'Women and wine, game and deceit,
Make the wealth small, and the want great.'

And, further, 'What maintains one vice would bring up two children.' You may think, perhaps, that a little tea, or a little punch now and then, diet a little more costly, clothes a little finer, and a little entertainment now and then, can be no great matter; but remember what poor Richard says—'Many a little makes a mickle;' and farther, 'Beware of little expenses; a small leak will sink a great ship;' and again, 'Who dainties love shall beggars prove;' and moreover, 'Fools make feasts, and wise men eat them.'

Here you are all got together at this sale of fineries and nick-nacks. You call them *goods*; but if you do not take care, they will prove *evils* to some of you. You expect they will be sold cheap, and perhaps they may for less than they cost; but if you have no occasion for them, they must be dear to you. Remember what poor Richard says—'Buy what thou hast no need of, and ere long thou shalt sell thy necessities.' And again, 'At a great pennyworth pause a while.' He means, that perhaps the cheapness is apparently only, or not real, or the bargain, by straitening thee in thy business, may do thee more harm than good. For in another place he says, 'Many have been ruined by buying good pennyworths.' Again, as poor Richard says, 'It is foolish to lay out money in a purchase of repentance;' and yet this folly is practised every day at auctions, for want of minding the Almanac. 'Wise men (as poor Dick says) learn by others' harms, fools scarcely by their own; but *Felix quem faciunt aliena pericula cautum*.' Many people, for the sake of finery on the back, have gone with a hungry belly, and half starved their families: 'Silk and satins, scarlet and velvets (as poor Richard says), put out the kitchen fire.' These are not the necessities of life; they can scarcely be called the conveniences; and yet, only because they look pretty, how many want to have them! The artificial wants of mankind thus become more numerous than the natural; and as poor Dick says, 'For one poor person there

are a hundred indigent.' By these and other extravagances, the genteel are reduced to poverty, and forced to borrow of those whom they formerly despised, but who, through industry and frugality, have maintained their standing; in which case it appears plainly, 'A ploughman on his legs is higher than a gentleman on his knees,' as poor Richard says. Perhaps they have had a small estate left them which they knew not the getting of; they think 'It is day, and will never be night; that a little to be spent out of so much is not worth minding.' 'A child and a fool (as poor Richard says) imagine twenty shillings and twenty years can never be spent; but always taking out of the meal-tub, and never putting in, soon comes to the bottom;' then, as poor Dick says, 'When the well is dry, they know the worth of water.' But this they might have known before, if they had taken his advice: 'if you would know the value of money, go and try to borrow some; for he that goes a-borrowing goes a-sorrowing, and, indeed, so does he that lends to such people when he goes to get it in again.' Poor Dick further advises, and says,

'Fond pride of dress is sure a very curse;
Ere fancy you consult, consult your purse.'

And again, 'Pride is as loud a beggar as Want, and a great deal more saucy.' When you have bought one fine thing, you must buy ten more, that your appearance may be all of a piece; but poor Dick says, 'It is easier to suppress the first desire than to satisfy all that follow it.' And it is as truly folly for the poor to ape the rich, as the frog to swell in order to equal the ox.

'Vessels large may venture more,
But little boats should keep near shore.'

'Tis, however, a folly soon punished; for 'Pride that dines on vanity sups on contempt,' as poor Richard says. And in another place, 'Pride breakfasted with Plenty, dined with Poverty, and supped with Infamy.' And, after all, of what use is this pride of appearance, for which so much is risked, so much is suffered? It cannot promote health, or ease pain; it makes no increase of merit in the person; it hastens misfortune.

'What is a butterfly? At best
He's but a caterpillar drest;
The gaudy fop's his picture just,'

as poor Richard says.

But what madness must it be to run in debt for these superfluities! We are offered, by the terms of this sale, six months' credit, and that perhaps has induced some of us to attend it, because we cannot spare the ready money, and hope now to be fine without it. But, ah! think what you do when you run in debt. You give to another power over your liberty. If you cannot pay at the time, you will be ashamed to see your creditor; you will be in fear when you speak to him: you will make poor, pitiful, sneaking excuses, and by degrees come to lose your veracity, and sink into base downright lying; for, as poor Richard says, 'The second vice is lying; the first is running in debt.' And again, to the same purpose, 'Lying rides upon debt's back;' whereas, a freeborn Englishman ought not to be ashamed nor afraid to speak to any man living. But poverty often deprives a man of all spirit and virtue. 'It is hard for an empty bag to stand upright,' as poor Richard truly says. What would you think of that prince, or that government, who would issue an edict, forbidding you to dress like a gentleman or gentlewoman, on pain of imprisonment or servitude? Would you not say that you were free, have a right to dress as you please, and that such an edict would be a breach of your privileges, and such a government tyrannical? And yet you are about to put yourself under that tyranny when you run in debt for such dress! Your creditor has authority at his pleasure to deprive you of your liberty, by confining you in jail for life, or by selling you for a servant, if you should not be able to pay him. When you have got your bargain, you may perhaps think little of payment; but 'Creditors (poor Richard tells us) have better memories than debtors;' and in another place he says,

'Creditors are a superstitious sect, great observers of set days and times.' The day comes round before you are aware, and the demand is made before you are prepared to satisfy it; or if you bear your debt in mind, the term which at first seemed so long, will, as it lessens, appear extremely short. Time will seem to have added wings to his heels as well as at his shoulders. 'Those have a short Lent (saith poor Richard) who owe money to be paid at Easter.' Then since, as he says, 'The borrower is a slave to the lender, and the debtor to the creditor,' disclaim the chain, preserve your freedom, and maintain your independence: be industrious and free; be frugal and free. At present, perhaps, you may think yourselves in thriving circumstances, and that you can bear a little extravagance without injury; but

'For age and want save while you may,
No morning sun lasts a whole day,'

as poor Richard says. Gain may be temporary and uncertain; but ever, while you live, expense is constant and certain; and 'It is easier to build two chimneys, than to keep one in fuel,' as poor Richard says. So 'Rather go to bed supperless than rise in debt.'

'Get what you can, and what you get hold;
'Tis the stone that will turn all your lead into gold,'

as poor Richard says. And when you have got the philosopher's stone, surely you will no longer complain of bad times, or the difficulty of paying taxes.

This doctrine, my friends, is reason and wisdom; but, after all, do not depend too much upon your own industry, and frugality, and prudence, though excellent things; for they may be blasted without the blessing of Heaven: and therefore ask that blessing humbly, and be not uncharitable to those that at present seem to want it, but comfort and help them. Remember Job suffered, and was afterwards prosperous.

And now, to conclude, 'Experience keeps a dear school; but fools will learn in no other, and scarce in that; for it is true we may give advice, but we cannot give conduct,' as poor Richard says. However, remember this, 'They that will not be counselled cannot be helped,' as poor Richard says; and further, that 'If you will not reason, she will surely rap their knuckles.'

Thus the old gentleman ended his harangue. The people heard it, and approved the doctrine, and immediately practised the contrary, just as if it had been a common sermon; for the auction opened, and they began to buy extravagantly, notwithstanding all his cautions and their own fear of taxes. I found the good man had thoroughly studied my Almanacs, and digested all I had dropped on those topics during the course of twenty-five years. The frequent mention he made of me must have tired every one else; but my vanity was wonderfully delighted with it, though I was conscious that not a tenth part of the wisdom was my own, which he ascribed to me, but rather the gleanings that I had made of the sense of all ages and nations. However, I resolved to be the better for the echo of it; and though I had at first determined to buy stuff for a new coat, I went away, resolved to wear my old one a little longer.

As Franklin advanced in worldly prosperity, he endeavoured to make his personal acquirements keep pace with his upward progress in society; and amongst other accomplishments, applied himself sedulously to the study of the dead and modern languages, of which, besides his native tongue, he as yet scarcely knew any thing. The following is his own account of his private curriculum:—

"I had begun in 1733 to study languages. I soon made myself so much a master of the French, as to be able to read the books in that language with ease. I then undertook the Italian. An acquaintance, who was also learning it, used often to tempt me to play chess with him. Finding this took up too much of the time I had to spare for study, I at length refused to play any more, unless on this condition, that the victor in every game should have a right to impose a task, either of parts of the grammar to be got by heart, or in transla-

tions, &c., which tasks the vanquished was to perform upon honour before our next meeting. As we played pretty equally, we thus beat one another into that language. I afterwards, with a little pains-taking, acquired as much of the Spanish as to read their books also. I have already mentioned that I had only one year's instruction in a Latin school, and that when very young, after which I neglected that language entirely; but when I had attained an acquaintance with the French, Italian, and Spanish, I was surprised to find, on looking over a Latin Testament, that I understood more of that language than I had imagined, which encouraged me to apply myself again to the study of it; and I met with the more success, as those preceding languages had greatly smoothed my way."

CIVIC PREFERMENTS AND DUTIES.

It was not to be supposed that a man of Franklin's comprehensive mind, and useful practical talents, would be allowed to remain long in the ranks of private life. Accordingly, in the year 1736, he was appointed clerk to the General Assembly at Pennsylvania. No opposition was made to his appointment the first year; but on the next election, a new member of the house opposed his return in a long speech. Franklin was, however, again elected, much to his satisfaction; for although the place was one of almost no direct emolument, it gave him an opportunity of making friends amongst the members, and ultimately to secure to himself the printing of most of the public papers, which was previously shared with his rivals. The new member who had resisted his re-election was a man of talents and character; and Franklin, although too independent to pay any cringing servility to him, perceived the propriety of gaining his good opinion; and the expedient he hit upon for this purpose affords another instance of his shrewdness and knowledge of human nature. Having learned that the gentleman possessed a very rare and curious book, he wrote him a polite note, requesting that he would do him the favour of lending it for a few days. The book was immediately sent; and in about a week was returned by the borrower, with a short epistle, expressive of his gratitude for the favour. The member was so much conciliated by the circumstance, that the next time he met him in the house, he addressed him with great civility; manifested ever afterwards a great desire to serve him; and they became, in short, intimate friends. "This is another instance," observes Franklin, "of the truth of an old maxim I had learned, which says, 'He that has done you a kindness will be more ready to do you another than he whom you yourself have obliged.' And it shows how much more profitable it is prudently to remove, than to resent, return, and continue, inimical proceedings." He was thereafter re-elected to the same post, without opposition, for several years successively. In the following year, 1737, he supplanted his rival in trade, Bradford, in the office of deputy-postmaster for the state of Pennsylvania. These honourable preferments induced him to incline his thoughts to, and take a more active part in, public affairs than he had hitherto done.

He first turned his attention to a state of the city police, which was then in a shameful condition; and he soon effected a thorough reformation in the whole system. He suggested and promoted the establishment of a fire insurance company, the first that was projected in America. He afterwards successively exerted himself in organising a philosophical society, an academy for the education of youth, and a militia for the defence of the province. In short, every department of the civil government, as he tells us, and almost at the same time, imposed some duty upon him. "The governor," says he, "put me into the commission of the peace; the corporations of the city chose me one of the common council; and the citizens at large elected me (1747) a Burgess to represent them in assembly. This latter station was the more agreeable to me, as I grew at length tired with sitting there to hear the debates, in which, as clerk, I could take no part, and which were

often so uninteresting, that I was induced to amuse myself with making magic squares, or circles, or any thing, to avoid weariness; and I conceived my becoming a member would enlarge my power of doing good. I would not, however, insinuate that my ambition was not flattered by all these promotions—it certainly was: for considering my low beginning, they were great things to me; and they were still more pleasing as being so many spontaneous testimonies of the public good opinion, and by me entirely unsolicited."

About this period (1739), the celebrated preacher Whitfield arrived at Philadelphia from Ireland. He was at first permitted to preach in some of the town churches; but the clergy soon took a dislike to him, and he was compelled to exercise his eloquence in the open streets or fields. This circumstance, however, like all displays of persecution in matters exclusively connected with private opinion, only rendered him the more popular; and the effects of his oratory speedily manifested themselves.

"It was wonderful," says Franklin, "to see the change soon made in the manners of our inhabitants. From being thoughtless or indifferent about religion, it seemed as if all the world were growing religious, so that one could not walk through the town in an evening without hearing psalms sung in different families of every street; and it being found inconvenient to assemble in the open air, subject to its inclemencies, the building of a house to meet in was no sooner proposed, and persons appointed to receive contributions, than sufficient sums were soon received to procure the ground and erect the building, which was one hundred feet long and seventy broad; and the work was carried on with such spirit as to be finished in a remarkably short time."

On leaving Philadelphia, Mr Whitfield went, preaching all the way, through the colonies to Georgia. The settlement of that province had then been recently commenced, and was attempted by people entirely unfit for such an experiment. They were unable to endure the fatigues and hardships of their situation, and perished in great numbers, leaving many helpless children with nothing to feed or clothe them. "The sight of their miserable situation," says Franklin, "inspired the benevolent heart of Mr Whitfield with the idea of building an orphan house there, in which they might be supported and educated. Returning northward, he preached up this charity, and made large collections; for his eloquence had a wonderful power over the hearts and purses of his hearers, of which I myself was an instance. I did not disapprove of the design; but as Georgia was then destitute of materials and workmen, and it was proposed to send them from Philadelphia at a great expense, I thought it would have been better to have built the house at Philadelphia, and brought the children to it. This I advised; but he was resolute in his first project, rejected my proposal, and I therefore refused to contribute.

I happened soon after to attend one of his sermons, in the course of which I perceived he intended to finish with a collection, and I silently resolved he should get nothing from me. I had in my pocket a handful of copper, three or four silver dollars, and five pistoles in gold. As he proceeded, I began to soften, and concluded to give the copper. Another stroke of his oratory made me ashamed of that, and determined me to give the silver; and he finished so admirably, that I emptied my pocket wholly into the collector's dish, gold and all!"

At this time there was no military defensive force in Pennsylvania. The inhabitants were mostly Quakers, and neglected to take any measures of precaution against the dangers to which, from the French possessions in Canada, they were continually exposed. All the exertions of the governor of the province to induce the Quaker assembly to pass a militia law, proved ineffectual. Franklin thought something might be done by a subscription among the people; and to pave the way for this, he wrote and published a pamphlet called

"Plain Truth." In this he clearly exposed their helpless and perilous situation, and demonstrated the necessity of co-operating for their mutual defence. The pamphlet had a sudden and surprising effect. A meeting of the citizens was held, at which proposals of the intended union, previously drawn up and printed by Franklin, were distributed about the room, to be signed by those who approved of them; and when the company separated, it was found that above twelve hundred signatures had been appended to the papers. Other copies were distributed through the province, and the subscribers at length amounted to upwards of ten thousand! All these individuals furnished themselves, as soon as they could, with arms; formed themselves into companies and regiments; chose their officers, and had themselves regularly instructed in military exercises. The women made subscriptions amongst themselves, and provided silk colours, which they presented to the companies, embellished with devices and mottoes furnished by Franklin. Such influence has one master-mind amongst his fellows in a time of emergency!

Franklin's modesty, however, was more than commensurate with his patriotism. The officers of the companies composing the Philadelphia regiment unanimously chose him for their colonel, but he declined the office in favour of a man of greater wealth and influence, who, on his recommendation, was immediately elected. These exertions of Franklin procured him great confidence from the governor and council, who consulted him on all their public measures. Notwithstanding, too, of the passive principles of the Quakers, it was soon seen that the precautions of military defence were any thing but disagreeable to them. A distinguished individual of their number, Mr Logan, published an address declaring his approbation of defensive war, and supporting his opinion by able and elaborate arguments.

This gentleman, who came over from England when a young man, as secretary to the famous William Penn, used to relate an anecdote respecting his old master, which is sufficiently amusing. During their voyage, they were chased by an armed vessel, supposed to be an enemy. Their captain prepared for defence, but told Penn and his company of Quakers that he did not expect their assistance, and that they might retire into the cabin. This notification they all complied with, excepting Logan, who remained on deck, and was quartered to a gun. The supposed enemy proved a friend, so that there was no fighting; but when the secretary carried the joyful news for his friends in the cabin, Penn reproved him severely for staying on deck, and lending his assistance in defence of the vessel, as being a breach of the principles of their society. Logan, nettled at this comment on his courageous conduct, which was made before the whole company, replied, "I being thy servant, why did thee not order me to come down? but thee was willing enough that I should stay and help to fight the ship, when thee thought there was danger!"

ELECTRICAL DISCOVERIES.

It would, perhaps, have been desirable to have followed Franklin through the remainder of his public and political career, without pausing to advert to other pursuits, entirely unconnected therewith, to which he devoted himself. We find, however, that the chronological violence of which we would in that case necessarily be guilty, would only serve to confuse our narrative. We will now, therefore, proceed to introduce him to our readers in an entirely new character from any in which they have yet seen him; for, in the language of the poet, his truly was

"A mind so various that he seemed to be

Not one, but all mankind's epitome."

Down to the close of the sixteenth century, all that was known of the principle of electricity was the discovery of a power inherent in amber,* and one or two other

* The term electricity is derived from the Greek word *electron*, amber.

substances, to attract to them, when rubbed, light bodies, such as small bits of paper, straw, &c. In the year 1600, Dr Gilbert of London considerably enlarged the catalogue of these electrical or attractive substances, including the diamond and other precious stones, glass, sulphur, sealing wax, rosin, &c. For above a century afterwards, however, electricity was little attended to, although Dr Wall, Sir Isaac Newton, Guericke, and others (the latter of whom first observed the repulsive power and explosive quality of electricity), added some important facts. In 1728, it was discovered that electricity may be communicated from one body to another, even without these bodies being in contact.

The beginning of the year 1746 is memorable in the annals of electricity for the accidental discovery of the possibility of accumulating large quantities of the electric fluid, by means of what was called the Leyden jar, or phial. M. Cuneus, of that city, happened one day, while repeating some experiments which had been originally suggested by M. Von Kleist, Dean of the Cathedral in Camin, to hold in one hand a glass vessel, nearly full of water, into which he had been sending a charge from an electrical machine, by means of a wire dipped into it, and communicating with the prime conductor, or insulated non-electric, exposed in the manner we have already mentioned to the action of the excited cylinder. He was greatly surprised, upon applying his other hand to disengage the wire from the conductor, when he thought that the water had acquired as much electricity as the machine could give it, by receiving a sudden shock in his arms and breast, much more severe than any thing of the kind he had previously encountered in the course of his experiments. The same thing, it was found, took place when the glass was covered, both within and without, with any other conductors than the water and the human hand, which had been used in this instance; as, for example, when it was coated on both sides with tinfoil, in such a manner, however, that the two coatings were completely separated from each other, by a space around the lip of the vessel being left uncovered. Whenever a communication was formed by the interposition of a conducting medium between the inside and outside coating, an instant and loud explosion took place, accompanied with a flash of light, and the sensation of a sharp blow, if the conductor employed was any part of the human body. The first announcement of the wonders of the Leyden phial excited the curiosity of all Europe. The accounts given of the electric shock by those who first experienced it are perfectly ludicrous, and well illustrate how strangely the imagination is acted upon by surprise and terror, when novel or unexpected results suddenly come upon it.

The extraordinary phenomena of the Leyden jar, soon, of course, attracted the attention of Franklin, and his inquisitive mind set itself to find out the reason of such strange effects, which astonished and perplexed the ablest philosophers of Europe. Out of his speculations arose the ingenious and beautiful theory of the action of the electric influence which is known by his name, and which has ever been received as the best, because the simplest and most complete, demonstration of the phenomena that has yet been propounded. His earliest inquiries were directed to ascertain the source of the electricity, which friction made manifest in the glass cylinder. This he demonstrated, by experiments, to be in the pores of the glass, and not in the coating, as previously supposed. After the cylinder, or phial (as it is frequently termed), was charged, he removed the coating, and found that, by applying a new coating, the shock might still be received. He showed clearly, that, when charged, the cylinder contained no more electricity than before, but that as much was taken from one side as was thrown on the other, and that by making a communication between the inside and outside coating, by which, as has already been seen, a loud explosion was caused, the equilibrium was at once restored. In order to determine whether the virtue was created by the friction in the electric, or only communicated to it

by other bodies, he resorted to the very simple experiment of endeavouring to electrify himself—that is to say, having insulated himself, and excited the cylinder by rubbing it with his hand, he then drew off its electricity from it in the usual manner into his own body. But he found that he was not thereby electrified at all, as he would have been by doing the same thing, had the friction been applied by another person. No spark could be elicited from him, after the operation by the presentment of a conductor. It was plain, therefore, that the electricity had passed in the first place out of his own body into the cylinder; which, therefore, in communicating it to him in the second instance, only gave back what it had received, and, instead of electrifying him, only restored him to his natural state. To prove this still farther, he insulated two individuals, one of whom he made to rub the cylinder, while the other drew the electricity from it. In this case, they were both affected; the one having given out as much electricity to the cylinder in rubbing it, as the other had drawn from it. In proof of this, he made them touch one another, when both were instantly restored to their usual state. The spark produced by their contact was also greater than that which took place when either of them was touched by an unelectrified person. From these results, then, Franklin constructed his theory, that every body in nature has a natural quantity of electricity, which may be diminished or increased in the way we have just described. In the former case he regarded the body as *negatively*, in the latter as *positively*, electrified. In the one case it had less, in the other more, than its natural quantity of electricity; in either, therefore, supposing it to be composed of electricity and common matter, the usual equilibrium or balance between its two constituent ingredients was for the time upset or destroyed.

But to return to the Leyden phial: Franklin was not contented with merely ascertaining the principle of it. He made also a very happy application of this principle, which afforded a still more wonderful manifestation than had yet been obtained of the powers of accumulated electricity. Considering the waste that took place, in the common experiment, of the fluid expelled, during the process of charging, from the exterior coating, he conceived the idea of employing it to charge the inner surface of a second jar, which he effected, of course, by the simple expedient of drawing it off by means of a metal rod communicating with that surface. The electricity expelled from the outside of this second jar was conveyed, in like manner, into the inside of a third; and in this way, a great number of jars were charged with the same facility as a single one. Then, having connected all the inside coatings with one conductor, and all the outside coatings with another, he had merely to bring these two general conductors into contact or communication, in order to discharge the whole accumulation at once. This contrivance he called an *Electrical Battery*. The general sketch we have thus given will put the reader in possession at least of the great outlines of the Franklinian theory of electricity, undoubtedly one of the most beautiful generalisations to be found in the whole compass of science.

We now advert to another brilliant discovery by this illustrious philosopher, namely, the similarity between lightning and electricity. The Abbé Nollet had, before him, hinted his suspicions of this resemblance, but only in the most loose and distant way.

In a paper, dated Nov. 7, 1749, Franklin enumerates all the known points of resemblance between lightning and electricity. In the first place, he remarks, it is no wonder that the effects of the one should be so much greater than those of the other; for if two gun-barrels electrified will strike at two inches' distance, and make a loud report, at how great a distance will ten thousand acres of electrified cloud strike, and give out fire; and how loud must be that crack! He had known for some time the extraordinary power of pointed bodies, both in drawing and in throwing off the electric fire. The true explanation of this fact did not occur to him; but it is

a direct consequence of the fundamental principle of his own theory, according to which the repulsive tendency of the particles of electricity towards each other, occasioning the fluid to retire, in every case, from the interior to the surface of bodies, drives it with especial force towards points and other prominences, and thus favours its escape through such outlets; while, on the other hand, the more concentrated attraction which the matter of a pointed body, as compared with that of a blunt one, exerts upon the electricity to which it is presented, brings it down into its new channel in a denser stream. In possession, however, of the fact, we find him concluding the paper we have mentioned as follows:—"The electric fluid is attracted by points. We do not know whether this property be in lightning; but since they agree in all the particulars in which we can already compare them, it is not improbable that they agree likewise in this. Let the experiment be made."

Full of this idea, his attention was one day drawn to a kite which a boy was flying, and it suddenly occurred to him that here was a method of reaching the clouds preferable to any other. Accordingly, he immediately took a large silk handkerchief, and, stretching it over two cross sticks, formed in this manner his simple apparatus for drawing down the lightning from its cloud. Soon after, seeing a thunder storm approaching, he took a walk into a field in the neighbourhood of the city, in which there was a shed, communicating his intentions, however, to no one but his son, whom he took with him to assist him in raising the kite: this was in June 1752.

The kite being raised, he fastened a key to the lower extremity of the hempen string, and then insulating it by attaching it to a post by means of silk, he placed himself under the shed, and waited the result. For some time no signs of electricity appeared. A cloud, apparently charged with lightning, had even passed over them without producing any effect. At length, however, just as Franklin was beginning to despair, he observed some loose threads of the hempen string rise and stand erect, exactly as if they had been repelled from each other by being charged with electricity. He immediately presented his knuckle to the key, and, to his inexpressible delight, drew from it the well-known electrical spark. He said afterwards that his emotion was so great at this completion of a discovery which was to make his name immortal, that he heaved a deep sigh, and felt that he could that moment have willingly died. As the rain increased, the cord became a better conductor, and the key gave out its electricity copiously. Had the hempen been thoroughly wet, the bold experimenter might, as he was contented to do, have paid for his discovery with his life. He afterwards brought down the lightning into his house, by means of an insulated iron rod, and performed with it, at his leisure, all the experiments that could be performed with electricity. But he did not stop here. His active and practical mind was not satisfied even with the splendid discovery, until he had turned it to a useful end. It suggested to him, as is well known, the idea of a method of preserving buildings from lightning, which is extremely simple and cheap, as well as effectual, consisting, as it does, in nothing more than attaching to the building a pointed metallic rod, rising higher than any part of it, and communicating at the lower end with the ground. This rod the lightning is sure to seize upon, in preference to any part of the building; by which means it is conducted to the earth, and prevented from doing any injury. There was always a strong tendency in Franklin's philosophy to these practical applications.

Franklin's discoveries did not at first attract much attention in England; and, in fact, he had the mortification to hear that his paper on the similarity between lightning and electricity had been ridiculed when read in the Royal Society. Having fallen, however, into the hands of the naturalist Buffon, that celebrated man translated and published it at Paris, when it speedily excited the astonishment of all Europe. What gave

his book the more sudden and general celebrity, was the success of one of its proposed experiments for drawing lightning from the clouds, made at Marly. This engaged the public attention every where. The "Philadelphia experiments," as they were called, were performed before the king and court, and all the curious of Paris flocked to see them. Dr Wright, an English physician, being at Paris at the time, wrote to a member of the Royal Society of London, with an account of these wonders, and stating the surprise of all the learned men abroad of Franklin's writings being so little noticed in England. The society were thus in a manner compelled to pay more attention to what they had previously considered as chimerical speculations, "and soon," says Franklin, "made me more than amends for the slight with which they had before treated me. Without my having made any application for that honour, they chose me a member, and voted that I should be excused the customary payments, which would have amounted to twenty-five guineas, and ever since have given me their Transactions gratis. They also presented me with the gold medal of Sir Godfrey Copley for the year 1753, the delivery of which was accompanied with a very handsome speech of the president, Lord Macclesfield, wherein I was highly honoured."

Although the numerous important public duties which Franklin was called upon latterly to discharge, chiefly engrossed his time, he still returned to his philosophical studies on every occasion that offered, and made several curious and interesting discoveries.

Perhaps no philosopher ever stood on a prouder eminence in the world's eye than Franklin during the latter half of his life. The obscurity of his origin served but to make his elevation the more brightly conspicuous; and honours were showered on him from all quarters of the civilised world. In 1757 he visited England, and before his return made a tour in Scotland, where he formed an intimacy with Lord Kames, and had the degree conferred upon him of Doctor of Laws by the University of St Andrews. In 1764 he again visited England, from which he proceeded to the continent of Europe. In Holland, Germany, and France, he was received with the greatest testimonies of respect from all men of science and distinction. At Paris, Louis XV. honoured him with the most distinguished marks of his favour.

POLITICAL CAREER.

This part of Franklin's life need only be very generally touched on, the scenes and transactions in which he bore a part having long since become matter of history, with which almost every individual is now more or less acquainted. We have before mentioned that he was elected a member of the General Assembly of Pennsylvania, as burgess for the city of Philadelphia, in 1747. Warm disputes at this time subsisted between the assembly and the proprietaries,* each contending for what they conceived to be their just rights. Franklin, a friend to the interests of the *many* from his infancy, speedily distinguished himself as a steady opponent of the claims of the proprietaries, and he was soon looked up to as the head of the opposition. His influence with the assembly is said to have been very great. This arose not from any superior powers of elocution; he spoke but seldom, and he never was known to make any thing like an elaborate harangue. "His speeches," says his intimate friend, the late Dr Stuber of Philadelphia, "frequently consisted of but a single sentence, or of a well-told story, the moral of which was always obviously to the point. He never attempted the flowery fields of oratory. His manner was plain and mild; his style of speaking was, like that of his writings, simple, unadorned, and remarkably concise. With this plain manner, and his penetrating and solid judgment, he was able to confound the most eloquent and subtle of his adversaries, to confirm the opinions of his friends, and

* The descendants of the original settlers who had received grants of land from the British government, who claimed exemption from all taxes, and other privileges.

to make converts of the unprejudiced who had opposed him. With a single observation, he has rendered of no avail an elegant and lengthy discourse, and determined the fate of a question of importance."

Franklin had conducted himself so well in the office of postmaster for the state of Pennsylvania, and had shown himself so well acquainted with the business of that department, that it was thought expedient to raise him to a more dignified station. In 1753, he was appointed deputy-postmaster-general for the British colonies. It is said that the revenue from this source, in Franklin's hands, yielded to Great Britain three times as much as that of Ireland. In 1754, Franklin drew up the celebrated "Albany Plan of Union," the purpose of which was the establishment of a general government in the colonies, to be administered by a president-general, appointed by the crown, and by a grand council, consisting of members chosen by the representatives of the different colonies; the whole executive authority to be committed to the president-general; the legislative to the grand council and president jointly; and all laws to be approved of by the king. This plan was unanimously approved of by the commissioners for the crown and the colonies appointed to consult on the question, but its final fate was singular. It was rejected by the ministry of Great Britain as too democratical, and by every local assembly as too despotic. These verdicts were, perhaps, the best proof of its excellence, and of its having steered exactly in the middle betwixt the interests of both.

The British government having thus rejected a proposal of internal defence in the colonies, they were soon obliged to adopt measures of another sort for their protection. Aggressive operations were again threatened by the French; and in 1754, General Braddock was dispatched from England with two regiments of regular English troops to resist them. The troops were landed at Alexandria, and marched thence to Fredericks town in Maryland, where they halted for carriages to transport their baggage, ammunition, &c., to the frontiers. Great reluctance was manifested by the country people to supply these, and, in fact, so few were sent in, and so many other difficulties occurred, that the general was about to abandon the expedition altogether. In this dilemma he was fortunately joined by Franklin, who, aware of the necessity and importance of the expedition, asked General Braddock what recompense he would afford to the owners for the use of their waggons and horses. General Braddock referred the terms to himself; they were drawn up and accepted; and Franklin immediately published them in an advertisement, with an animated appeal from himself to the loyalty and patriotism of his countrymen. The consequence was, that, in two weeks, 150 waggons and 260 horses poured into the camp, the owners of which, however, declined the security of the British commander for compensation, and insisted on having the personal bond of Franklin. This he accordingly gave them, and even advanced several hundred pounds of his own in present payment.

The expedition accordingly set forward, and its disastrous issue must still be well remembered. Although a brave man, Braddock had far too much confidence in the prowess of his regular troops, and too much contempt for the Americans and Indians. About one hundred of the latter joined him on his march, who would have proved of the utmost use to him as guides and scouts, but he treated them so slightly that they all left him. No appearance of the enemy was seen until the troops had penetrated far into the interior; and the first intelligence which they had of the approach of a foe, was in finding that they had fallen into an ambuscade, where they were mowed down in hundreds by invisible antagonists secreted amongst the trees and bushes. A general rout and confusion almost immediately ensued. The drivers cut their horses' traces and fled, abandoning the waggons, which also obstructed the retreat of the soldiers. The general was with difficulty brought off, severely wounded; and, out of eighty-

six officers, sixty-three were killed or wounded, with seven hundred and fourteen privates killed, out of eleven hundred who fell into the snare. All the artillery and stores, of course, were left to the enemy.

As soon as the news of the defeat, and the loss of the waggons and horses, became generally known, the owners came in a body upon Franklin for the amount of their claims, for which he had given bond, amounting to nearly £20,000! It was with difficulty that many of these claimants were prevented from suing him, until government had time to examine into their charges and order payment; but the matter was at length satisfactorily settled.

The assembly now laid a tax, to raise money for the defence of the province, and Franklin was appointed one of the commissioners to dispose of it. He had also carried a bill through the house for establishing and disciplining a voluntary militia. To promote the association necessary to form the militia, he wrote a dialogue upon the subject, which was extensively circulated, and thought to have great effect. While the several companies in the city and country were forming and learning their exercise, the governor prevailed upon Franklin to take charge of the north-western frontier, which was infested by the enemy, and provide for the defence of the inhabitants, by raising troops, and building a line of forts. Franklin did not think himself very well qualified for the military, but was willing to be of all the service in his power. He received a commission from the governor, with full authority, and a parcel of blank commissions for officers, to be given to whom he thought fit. Five hundred and sixty men were soon raised and placed under his command.

The first place selected for the erection of a fort was Gnadenhutzen, a small settlement of Moravians; and thither Franklin set out in the middle of winter, amid torrents of rain, and through almost impassable roads. Upon arriving at the village, he lost not a moment in planning and marking out the fort, with a circumference of 455 feet; and the men were instantly set to work with their axes to cut down trees for palisades. Seeing the trees fall so fast, Franklin had the curiosity to look at his watch when two men began to cut at a pine. In six minutes they had it upon the ground, and it was fourteen inches in diameter. Each pine made three palisades, of eighteen feet long, pointed at one end. While these were preparing, other men dug a trench all round, of three feet deep, in which the palisades were to be planted. When these were set up, the carpenters built within them a platform of boards all round, about six feet high, for the men to stand on and fire through the loopholes. They had one swivel gun, which they mounted, and fired as soon as it was fixed, that the Indians might know they had such pieces. Thus their fort, such as it was, was finished in a week, though it rained so hard every other day that the men were almost unable to work.

"This gave me occasion to observe," says Franklin, "that when men are employed they are best contented. For on the days they worked, they were good-natured and cheerful, and, with the consciousness of having done a good day's work, they spent the evening gaily. But, on our idle days, they were mutinous and quarrelsome, finding fault with the pork and the bread, and were continually in bad humour; which put me in mind of a sea captain, whose rule it was to keep his men constantly at work; and when his mate once told him that they had done every thing, and there was nothing further to employ them about, 'Oh,' said he, 'make them scour the anchor.'"

This kind of fort," he continues, "however contemptible, is a sufficient defence against Indians, who have no cannon. Finding ourselves now posted securely, and having a place to retreat to on occasion, we ventured out in parties to scour the adjacent country. We met with no Indians, but we found the places on the neighbouring hills where they had lain to watch our proceedings. There was an art in their contrivance of those places that seems worth mentioning.

It being winter, a fire was necessary for them; but a common fire, on the surface of the ground, would by its light have discovered their position at a distance; they had therefore dug holes in the ground about three feet in diameter, and somewhat deeper; we found where they had, with their hatchets, cut off the charcoal from the side of burnt logs lying in the woods. With these coals they had made small fires in the bottom of the holes; and we observed among the weeds and grass the prints of their bodies made by their lying all round, with their legs hanging down in the holes, to keep their feet warm, which with them is an essential point. This kind of fire, so managed, could not discover them either by its light, flame, sparks, or even smoke: it appeared that the number was not great, and it seems they saw we were too many to be attacked by them with a prospect of advantage.

We had for our chaplain a zealous Presbyterian minister, Mr Beatty, who complained to me that the men did not generally attend his prayers and exhortations. When they enlisted they were promised, besides pay and provisions, a gill of rum a-day, which was punctually served out to them, half in the morning and half in the evening, and I observed they were punctual in attending to receive it." Franklin advised that the rum should be distributed only just after prayers; and never were prayers more generally or more punctually attended.

Franklin's military career was, however, a short one; for he had scarcely completed his defensive preparations, when he received a summons to attend the assembly, where his advice and assistance were found indispensable.

The disputes between the proprietaries and the people, before referred to, continued to increase in 1755 and 1756, although a war was then raging on the frontiers—the French having still possession of Canada. The popular assemblies insisted on the justice of taxing the proprietary estates; but the governors constantly refused to assent to such a measure. The assemblies at last resolved to appeal to the mother country; and a petition was accordingly made out, addressed to the king in council. Franklin was appointed to present this address, as agent for the province of Pennsylvania, and departed for England in June 1757. During this time, the governor passed a law imposing a tax, in which no discrimination was made in favour of the estates of the Penn family, which were immensely large. The Penns thereupon used their most strenuous exertions to prevent its passing into a law. After long debate and deliberation, a proposal was made that Franklin should *personally* engage that the proprietary estates should pay no more than a just proportion of the tax. This he agreed to do—the proprietaries withdrew their opposition, and tranquillity was once more restored to the province. The manner in which this dispute was terminated sufficiently evinces the high confidence entertained of Franklin's honour and integrity, even by those opposed to his political views. After this, Franklin remained some time at the British court, having, besides Pennsylvania, been also appointed agent for the states of Massachusetts, Maryland, and Georgia.

The French in Canada still continuing to molest and interrupt the trade of the other colonies, Franklin published his famous Canada pamphlet, in which he in a forcible manner pointed out the advantages which would result from the conquest of that province. An expedition was accordingly sent out under General Wolfe, the result of which is well known. At the treaty in 1762, France ceded Canada to Great Britain, and by her cession of Louisiana at the same time, relinquished all her possessions on the continent of America.

In the summer of 1762, Franklin returned to America, and received the thanks of the Assembly of Pennsylvania, as well for the faithful discharge of his duty to that province in particular, as for the many and important services done to America in general, during his residence in Great Britain. A compensation of £5000, Pennsylvania currency, was likewise decreed

him for the services he had performed in England. He was also immediately re-elected to his seat in the assembly.

Upon the breaking out of the fatal disturbances in consequence of Mr Grenville's Stamp Act, Franklin had again returned to England, as agent for Pennsylvania and other states. During his residence in England, he consulted, with unremitting industry, the best interests of his native country. He was every where received with respect, on account of his reputation as a writer and philosopher. Franklin was unwearied in his efforts to bring about a reconciliation. He had frequent interviews with Lord Howe and Lord Chatham, and other distinguished English statesmen, who entertained for him the highest respect and esteem. Most of the time during his present residence in England was occupied in these vain efforts. It is well known that the first violent demonstrations against the imposition of the Stamp Act, broke out in Franklin's native place, Boston, the capital of the state of Massachusetts. The governor, Hutchinson, and other functionaries, wrote to the home government, recommending the adoption of the most rigorous coercive measures, and inveighing in unmeasured terms against the leading characters of the state. By some unaccountable means, these letters fell into Franklin's hands ere they reached their destination. He instantly transmitted them back to the assembly at Massachusetts, who, enraged at the conduct of the governor, sent a petition to the king, praying for his dismissal, and Franklin was appointed to present it. As might have been expected, the petition was dismissed as "frivolous and vexatious;" and Franklin incurred so much obloquy for his interception of the governor's dispatches (the mode of which was never discovered), that he was dismissed from his office of deputy-postmaster-general. He still continued in England, however, and left nothing untried to effect a reconciliation between the mother-country and the colonies; but finding all his endeavours unavailing, he returned to America in 1775. The day after his arrival, he was elected by the legislature of Pennsylvania as a delegate to Congress. Hostilities had then commenced: but it would be repeating a thrice-told tale to enter into any account of the protracted and bloody struggle that ensued, or the nature of its termination. In 1778, Franklin was sent as ambassador to the court of France, where he soon brought about an alliance between that nation and the North American states. When the British ministry at length saw the necessity of recognising the independence of the states, the definitive treaty to that effect was signed at Paris on the 3d of September 1783, by Dr Franklin, Mr Adams, and Mr Jay, for the states, on the one hand; and by Mr David Hartley, for Great Britain, on the other. Franklin continued at Paris for the two following years; but at last, by his own urgent request, was recalled. Shortly after his return, he was elected president of the supreme executive council, and lent all his still perfect energies to consolidating the infant government. Age and infirmities, however, claimed their usual ascendancy; and in 1788 he retired wholly from public life.

DEATH.

Franklin's last public act—and it was one in beautiful accordance with the whole tenor of his life—was putting his signature, as president of the Anti-Slavery Society, to a memorial presented to the House of Representatives, praying them to exert the full powers intrusted to them to discourage the revolting traffic in the human species. This was on the 12th of February 1789. From this day forward, he was confined almost constantly to bed with the stone, from which he suffered the most excruciating agony. Yet, when his paroxysms of pain drew forth, as they did occasionally, an irrepressible groan, he would observe, he was afraid he did not bear his sufferings as he ought—acknowledged his grateful sense of the many blessings he had received from the Supreme Being, who had raised him from small and low beginnings to such high rank and consideration

among men, and made no doubt but his present afflictions were kindly intended to wean him from a world in which he was no longer fit to act the part assigned him. He latterly sunk into a calm lethargic state; and, on the 17th April 1790, about eleven o'clock at night, he quietly expired. He was then aged exactly eighty-four years and three months. The following epitaph, written by himself many years previous to his death, was inscribed on his tombstone:—

"The Body of BENJAMIN FRANKLIN, Printer [like the cover of an old book, its contents torn out, and strip of its lettering and gilding], lies here food for worms; yet the work itself shall not be lost, for it will (as he believed) appear once more in a new and more beautiful edition, corrected and amended by THE AUTHOR."

CHARACTER.

In looking back on Franklin's career, it is evident that the principal feature in his character was *worldly prudence*—not in the usual and selfish acceptance of the term, but that prudence, founded on true wisdom, which dictates the practice of honesty, industry, frugality, temperance, in short, all those qualities which may be classified under the name of "moral virtues"—as being the only certain means of obtaining distinction, respect, independence, and mental cheerfulness. There is no other writer who inculcates lessons of practical wisdom in a more agreeable and popular manner, and we much regret that the limits of this sheet prevent our giving many extracts illustrative of this quality. His whole conduct and writings, indeed, present the somewhat singular union of great genius with practical good sense, and of singular worldly shrewdness with the loftiest integrity of principle. The greatest worldly honours—and few have attained higher—could not for a moment make him forget or deviate from the principles with which he started in life. Ever keeping before his mind his own origin and rise, he justly considered every man to be originally on a par in as far as regarded real intrinsic worth; and, equally by precept and example, contributed more, perhaps, than any individual who ever existed, to breaking down those invidious bars to eminence and success in life which the conventional habits and artificial feelings of society had theretofore interposed to the elevation of those unblessed by birth and fortune.

As the present biography must be considered as more immediately instructive to the industrious and productive portion of mankind, we shall conclude it by giving the following "Advice to a Young Tradesman," written by Franklin at the time when his industrious and frugal habits were just beginning to be rewarded with independence and worldly respect.

"Remember that *time* is money. He that can earn ten shillings a-day by his labour, and goes abroad, or sits idle one-half of that day, though he spends but sixpence during his diversion or idleness, ought not to reckon that the only expense; he has really spent, or rather thrown away, five shillings besides.

Remember that *credit* is money. If a man lets his money lie in my hands after it is due, he gives me the interest, or so much as I can make of it during that time. This amounts to a considerable sum where a man has good and large credit, and makes good use of it.

Remember that money is of a prolific, generating nature. Money can beget money, and its offspring can beget more, and so on. Five shillings turned is six; turned again is seven and threepence; and so on till it becomes a hundred pounds. The more there is of it, the more it produces every turning, so that the profits rise quicker and quicker. He that kills a breeding sow, destroys all her offspring to the thousandth generation. He that murders a crown, destroys all that it might have produced, even scores of pounds.

Remember that six pounds a-year is but a groat a-day. For this little sum (which may be daily wasted either in time or expense, unperceived) a man of credit may, on his own security, have the constant possession

and use of a hundred pounds. So much in stock, briskly turned by an industrious man, produces great advantage.

Remember this saying, 'The good paymaster is lord of another man's purse.' He that is known to pay punctually, and exactly to the time he promises, may at any time, and on any occasion, raise all the money his friends can spare. This is sometimes of great use. After industry and frugality, nothing contributes more to the raising of a young man in the world than punctuality and justice in all his dealings: therefore, never keep borrowed money an hour beyond the time you promised, lest a disappointment shut up your friend's purse for ever.

The most trifling actions that affect a man's credit are to be regarded. The sound of your hammer at five in the morning, or nine at night, heard by a creditor, makes him easy six months longer; but if he sees you at a billiard-table, or hears your voice at a tavern, when you should be at work, he sends for his money the next day; demands it before he can receive it in a lump.

It shows, besides, that you are mindful of what you owe; it makes you appear a careful as well as an honest man, and that still increases your credit.

Beware of thinking all your own that you possess, and of living accordingly. It is a mistake that many people who have credit fall into. To prevent this, keep an exact account, for some time, both of your expenses and your income. If you take the pains at first to mention particulars, it will have this good effect—you will discover how wonderfully small trifling expenses mount up to large sums, and will discern what might have been, and may for the future be saved, without occasioning any great inconvenience.

In short, the way to wealth, if you desire it, is as plain as the way to market. It depends chiefly on two words—*industry* and *frugality*; that is, waste neither *time* nor *money*, but make the best use of both. Without industry and frugality nothing will do, and with them every thing. He that gets all he can honestly, and saves all he gets (necessary expenses excepted), will certainly become *rich*—if that Being who governs the world, to whom all should look for a blessing on their honest endeavours, doth not, in his wise providence, otherwise determine."

About forty years later, after a long life of experience, he penned the following similar admonitions, entitled, "Necessary Hints to those that would be Rich":—

"The use of money is all the advantage there is in having money.—For six pounds a-year you may have the use of one hundred pounds, provided you are a man of known prudence and honesty.—He that spends a groat a-day idly, spends idly about six pounds a-year, which is the price for the use of one hundred pounds. He that wastes idly a groat's worth of his time per day, one day with another, wastes the privilege of using one hundred pounds each year.—He that idly loses five shillings' worth of time, loses five shillings, and might as prudently throw five shillings into the sea.—He that loses five shillings, not only loses that sum, but all the advantages that might be made by turning it in dealing; which, by the time that a young man becomes old, will amount to a considerable sum of money.—Again; he that sells upon credit, asks a price for what he sells equivalent to the principal and interest of his money for the time he is to be kept out of it; therefore, he that buys upon credit, pays interest for what he buys; and he that pays ready money, might let that money out to use; so that he that possesses any thing he has bought, pays interest for the use of it.—Yet, in buying goods, it is best to pay ready money, because he that sells upon credit expects to lose five per cent. by bad debts; therefore, he charges, on all he sells upon credit, an advance that will make up that deficiency.—Those who pay for what they buy upon credit, pay their share of this advance.—He that pays ready money escapes, or may escape, that charge.

PRESERVATION OF HEALTH.

A HUMAN being, supposing him to be soundly constituted at first, will continue in health till he reaches old age, provided that certain conditions are observed, and no injurious accident shall befall. This is a proposition so well supported by an extensive observation of facts, that it may be regarded as established. It becomes, of course, important to ascertain what are the conditions essential to health, in order that, by their observance, we may preserve for ourselves what is justly esteemed as the greatest of earthly blessings, and dwell for our naturally appointed time upon the earth. A general acquaintance with these conditions may be easily attained by all, and to pay them obedience is much more within the power of individuals than is generally supposed.

The leading conditions essential to health may be thus enumerated:—1. A constant supply of pure air; 2. A sufficiency of nourishing food, rightly taken; 3. Cleanliness; 4. A sufficiency of exercise to the various organs of the system; 5. A right temperature; 6. A sufficiency of cheerful and innocent enjoyments; and, 7. Exemption from harassing cares.

AIR.

The common air is a fluid composed mainly of two gases, in certain proportions; namely, oxygen as 20 and nitrogen as 80 parts in a hundred, with a very minute addition of carbonic acid gas. Such is air in its pure and right state, and such is the state in which we require it for respiration. When it is loaded with any admixture of a different kind, or its natural proportions are in any way deranged, it cannot be breathed without producing injurious results. We also require what is apt to appear a large quantity of this element of healthy existence. The lungs of a healthy full-grown man will inhale the bulk of twenty cubic inches at every inspiration, and he will use no less than fifty-seven hogsheads in twenty-four hours.

Now, there are various circumstances which tend to surround us at times with vitiated air, and which must accordingly be guarded against. That first calling for attention is the miasma or noxious quality imparted to the air in certain districts by stagnant water and decaying vegetable matter. It is now generally acknowledged that this noxious quality is in reality a subtle poison, which acts on the human system through the medium of the lungs, producing fevers and other epidemics. A noted instance of its acting on a great scale is presented in the Campagna di Roma, where a large surface is retained in a marshy state. The air arising from that territory at certain seasons of the year, obliges the inhabitants of the adjacent districts of the city to desert their homes, in order to escape its pernicious influence. All marshes, and low damp grounds of every kind, produce more or less miasma, and it is consequently dangerous to live upon or near them. Slightly elevated ground

should, accordingly, in all cases, be chosen for both single houses and towns. Tanks and collections of water of every kind are dangerous beneath or near a house, because, unless their contents be constantly in a state of change, which is rarely the case, their tendency is to send up exhalations of a noxious kind. A few years ago, the eldest son of an English nobleman—a youth of great promise, and who had recently become a husband and father—died of a fever which was traced to the opening of an old reservoir of water underneath the country-house in which he dwelt.*

Putrid matter of all kinds is another conspicuous source of noxious effluvia. The filth collected in ill-regulated towns—ill-managed drains—collections of decaying animal substances, placed too near or within private dwellings—are notable for their effects in vitiating the atmosphere, and generating disease in those exposed to them. In this case, also, it is a poison diffused abroad through the air which acts so injuriously on the human frame. This was probably the main cause of the plagues which visited European cities during the middle ages. In those days there were no adequate provisions for cleaning cities, and the consequence was, that large collections of filth were accumulated. The noxious air diffused by these means through the narrow streets and confined dwellings would tend to the most fatal effects. In old drains there is generated a gas (sulphureted hydrogen), which is calculated to produce dreadful consequences amongst those exposed to it. It has lately been discovered, that it is the presence of this gas in the sea near the eastern coast of tropical Africa, which causes the peculiar unhealthiness of that region. It is ascertained that small animals, such as birds, die, when the air they breathe contains one fifteen-hundredth part of sulphureted hydrogen, and that an infusion six times greater will kill a horse. It follows, that we can scarcely attach too much importance to measures for cleaning cities and improving drains. There are as yet no large towns in Britain kept in a state so clean as is desirable for the health of their inhabitants; and the metropolis itself is amongst those which are most defective in this respect.

The human subject tends to vitiate the atmosphere for itself, by the effect which it produces on the air which it breathes. Our breath, when we draw it in, consists of the ingredients formerly mentioned; but it is in a very different state when we part with it. On passing into our lungs, the oxygen, forming the lesser ingredient, enters into combination with the carbon of the venous blood (or blood which has already performed its round through the body); in this process, about two-fifths of the oxygen is abstracted and sent into the blood, only the remaining three-fifths being expired, along with the nitrogen nearly as it was before.

* Viscount Milton, son of the present Earl Fitzwilliam, was the person here alluded to.

In place of the oxygen consumed, there is expired an equal volume of carbonic acid gas, such gas being a result of the process of combination just alluded to. Now, carbonic acid gas, in a larger proportion than that in which it is found in the atmosphere, is noxious. The volume of it expired by the lungs, if free to mingle with the air at large, will do no harm; but, if breathed out into a close room, it will render the air unfit for being again breathed. Suppose an individual to be shut up in an air-tight box: each breath he emits throws a certain quantity of carbonic acid gas into the air filling the box; the air is thus vitiated, and every successive inspiration is composed of worse and worse materials, till at length the oxygen is so much exhausted, that it is insufficient for the support of life. He would then be sensible of a great difficulty in breathing, and in a little time longer he would die.

Most rooms in which human beings live are not strictly close. The chimney and the chinks of the door and windows generally allow of a communication to a certain extent with the outer air, so that it rarely happens that great immediate inconvenience is experienced in ordinary apartments from want of fresh air. But it is at the same time quite certain that, in all ordinary apartments where human beings are assembled, the air unavoidably becomes *considerably vitiated*, for in such a situation there cannot be a sufficiently ready or copious supply of oxygen to make up for that which has been consumed, and the carbonic acid gas will be constantly accumulating. This is particularly the case in bedrooms, and in theatres, churches, and schools. An extreme case was that of the celebrated Black Hole of Calcutta, where a hundred and forty-six persons were confined for a night in a room eighteen feet square with two small windows. Here the oxygen scarcely sufficient for the healthy supply of one person, was called upon to support a large number. The unfortunate prisoners found themselves in a state of unhealed suffering, and in the morning all were dead but twenty-three, some of whom afterwards sunk under putrid fever brought on by breathing so long a tainted atmosphere.

Although the vitiation of the air in ordinary apartments and places of public assembly does not generally excite much attention, it nevertheless exercises a certain unfavourable influence on health in all the degrees in which it exists. Perhaps it is in bedrooms that most harm is done. These are generally smaller than other rooms, and they are usually kept close during the whole night. The result of sleeping in such a room is very injurious. A common fire, from the draught which it produces, is very serviceable in ventilating rooms, but it is at best a defective means of doing so. The draught which it creates generally sweeps along near the floor between the door and the fire, leaving all above the level of the chimney-piece unpurified. Yet scarcely any other arrangement is any where made for the purpose of changing the air in ordinary rooms. To open the window is a plan occasionally resorted to, but it is not always agreeable in our climate, and sometimes it produces bad consequences of a different kind.

It would nevertheless be easy to produce an effective draught from any room in which a fire is kept. It is only necessary to make an aperture into the flue, near the ceiling of the room, and insert therein a tin tube, with a valve at the exterior, capable of opening inwards, but closing when at rest or when a draught is sent the contrary way. The draught produced by the fire in the flue would cause a constant flow of air out of the *upper part* of the room (where most vitiated); and the valve would be an effectual protection against back-smoke, should there be the least tendency to it. This plan is adopted in Buckingham Palace. It could be applied to any existing house at a mere trifle of expense.

A more effectual plan, and one which operates when there is no fire in the room, is to establish a tin tube of two or three inches diameter out of each apartment to be ventilated, causing them all to meet in one general

tube, the extremity of which passes into some active flue—for example, that of the kitchen, which is rarely cold. Thus there might be a constant passing of fresh air into and through every room of a large house, so that it would be at all times as healthy in this respect as the open fields. At the same time, the supply might, by means of graduated valves, be regulated to any degree which might be deemed agreeable.

FOOD.

The second requisite for the preservation of health is a sufficiency of nutritious food.

Organic bodies, in which are included vegetables as well as animals, are constituted upon the principle of a *continual waste of substance supplied by continual nutrition*.

The Nutritive System of animals, from apparently the humblest of these to the highest, comprehends an *alimentary tube or cavity*, into which food is received, and from which, after undergoing certain changes, it is diffused by means of smaller vessels throughout the whole structure. In the form of this tube, and in the other apparatus connected with the taking of food, there are, in different animals, varieties of structure, all of which are respectively in conformity with peculiarities in the quality and amount of food which the particular animals are designed to take. The harmony to be observed in these arrangements is remarkably significant of that Creative Design to be traced in all things.

MAN DESIGNED TO LIVE ON A MIXED DIET.

Some animals are formed to live upon vegetable substances alone; others are calculated to live upon the flesh of other animals. Herbivorous animals, as the former are called, have generally a long and complicated alimentary tube, because the nutritious part of such food, being comparatively small in proportion to the whole bulk, requires a greater space in which to be extracted and absorbed into the system. The sheep, for example, has a series of intestines twenty-seven times the length of its body. For the opposite reasons, carnivorous or flesh-devouring animals, as the feline tribe of quadrupeds, and the rapacious birds, have generally a short intestinal canal. The former class of animals are furnished with teeth, calculated by their broad and flat surfaces, as well as by the lateral movement of the jaws in which they are set, to mince down the herbage and grain eaten by them. But the carnivorous animals, with wide-opening jaws, have long and sharp fangs to seize and tear their prey. These peculiarities of structure mark sufficiently the designs of nature with respect to the kinds of food required by the two different classes of animals for their support.

The human intestinal canal being of medium length, and the human teeth being a mixture of the two kinds, it necessarily follows that man was designed to eat both vegetable and animal food. As no animal can live agreeably or healthily except in conformity with the laws of its constitution, it follows that man will not thrive unless with a mixture of animal and vegetable food. The followers of Pythagoras argued, from the cruelty of putting animals to death, that it was proper to live on vegetables alone; and many eccentric persons of modern times have acted upon this rule. But the ordinances of Nature speak a different language; and, if we have any faith in these, we cannot for a moment doubt that a mixture of animal food is necessary for our well-being. On the other hand, we cannot dispense with vegetable food, without injurious consequences. In that case, we place in a medium alimentary canal a kind of food which is calculated for a short one, thus violating an arrangement of the most important nature. A balance between the two kinds of food is what we should observe, if we would desire to live a natural and consequently healthy life.

RULES CONNECTED WITH EATING.

In order fully to understand how to eat, what to eat,

and how to conduct ourselves after eating, it is necessary that we should be acquainted in some measure with the *process of nutrition*—that curious series of operations by which food is received and assimilated by our system, in order to make good the deficiency produced by waste.

Food is first received into the mouth, and there the operations in question may be said to commence. It is there to be chewed (or masticated) and mixed with saliva, preparatorily to its being swallowed or sent into the stomach. Even in this introductory stage, there are certain rules to be observed. Strange as it may appear, to know *how to eat* is a matter of very considerable importance.

Many persons, thinking it all a matter of indifference, or perhaps unduly anxious to dispatch their meals, eat very fast. If we are to believe the accounts of travellers, the whole of the mercantile classes in New England eat hurriedly, seldom taking more than ten minutes to breakfast, and a quarter of an hour to dinner. They tumble their meat precipitately into their mouths, and swallow it almost without mastication. This is contrary to an express law of nature, as may be easily shown.

Food, on being received into the mouth, has two processes to undergo, both very necessary to digestion. It has to be masticated, or chewed down, and also to receive an admixture of saliva. The saliva is a fluid arising from certain glands in and near the mouth, and approaching in character to the gastric juice afterwards to be described. Unless food be well broken down or masticated, and also well mixed up with the salivary fluid, it will be difficult of digestion. The stomach is then called upon to do, besides its own proper duty, that which properly belongs to the teeth and saliva, and it is thus overburdened and embarrassed, often in a very serious manner. The pains of indigestion are the immediate consequence, and more remote injuries follow.

The importance of the saliva has been shown in a striking manner, on several occasions when food was received into the stomach otherwise than through the mouth. A gentleman, who, in consequence of a stricture in the gullet, had his food introduced by an aperture into that tube, used to suffer severely from indigestion. It is recorded of a criminal, who, having cut his throat in prison without fatal consequences, required to get his food introduced by means of a tube inserted by the mouth, that, every time he was fed, there was an effusion of saliva to the amount of from six to eight ounces. We cannot suppose that a fluid of a peculiar character would have been prepared in such quantity, when water would serve as well merely to wet the food, if it had not been designed to act an important part in the business of nutrition. With regard to mastication, the evidence of its importance is still more clear. A few years ago, a young Canadian, named Alexis St Martin, had a hole made by a shot into his stomach, which healed without becoming closed. It was therefore possible to observe the whole operations of the stomach with the eye. His medical attendant, Dr Beaumont, by these means ascertained that, when a piece of solid food was introduced, the gastric juice acted merely on its outside. It was only when the food was comminuted, or made *small*, that this fluid could fully perform its function. When the stomach finds itself totally unable to digest a solid piece of food, it either rejects it by vomiting, or passes it on into the gut, where it produces an irritating effect, and is apt to occasion an attack of cholera or flatulency.

It is therefore to be concluded that *a deliberate mastication of our food is conducive to health, and that fast eating is injurious, and sometimes even dangerous.*

The food, having been properly masticated, is, by the action of the tongue, thrown into the gullet. It then descends into the stomach, not so much by its own gravity, as by its being urged along by the contractions and motions of the gullet itself. The stomach may be considered as an expansion of the gullet, and the chief part of the alimentary canal. It is, in fact,

a membranous pouch or bag, very similar in shape to a bagpipe, having two openings, the one by which the food enters, the other that by which it passes out. It is into the greater curvature of the bag that the gullet enters; it is at its lesser that it opens into that adjoining portion of the canal into which the half-digested mass is next propelled.

When food has been introduced, the two orifices close, and that which we may term the second stage in the process of digestion commences. The mass, already saturated with saliva, and so broken down as to expose all its particles to the action of the gastric juice, is now submitted to the action of that fluid, which, during digestion, is freely secreted by the vessels of the stomach. The most remarkable quality of this juice is its solvent power, which is prodigious.

The food exposed to this dissolving agency, is converted into a soft, grey, pulpy mass, called *chyme*, which, by the muscular contraction of the stomach, is urged on into the adjoining part of the alimentary canal, called the duodenum. This is generally completed in the space of from half an hour to two or three hours; the period varying according to the nature and volume of the food taken, and the mastication and insalivation it has undergone.

In the duodenum, the chyme becomes intimately mixed and incorporated with the bile and pancreatic juices; also with a fluid secreted by the mucous follicles of the intestine itself. The bile is a greenish, bitter, and somewhat viscid fluid, secreted by the liver, which occupies a considerable space on the right side of the body immediately under the ribs. From this organ the bile, after a portion of it has passed up into the adjacent gall-bladder, descends through a small duct, about the size of a goose-quill, into the duodenum. The chyme, when mixed with these fluids, undergoes a change in its appearance; it assumes a yellow colour and bitter taste, owing to the predominance of the bile in the mass; but its character varies according to the nature of the food that has been taken. Fatty matters, tendons, cartilages, white of eggs, &c., are not so readily converted into chyme as fibrous or fleshy, cheesy, and glutinous substances. The chyme, having undergone the changes adverted to, is urged by the peristaltic motion of the intestines onwards through the alimentary canal. This curious motion of the intestines is caused by the contraction of the muscular coat which enters into their structure, and one of the principal uses ascribed to the bile is that of stimulating them to this motion. If the peristaltic motion be diminished, owing to a deficiency of bile, then the progress of digestion is retarded, and the body becomes constipated. In such cases, calomel, the blue pill, and other medicines, are administered for the purpose of stimulating the liver to secrete the biliary fluid, that it may quicken by its stimulating properties the peristaltic action. But this is not the only use of the bile: it also assists in separating the nutritious from the non-nutritious portion of the alimentary mass, for the chyme now presents a mixture of a fluid termed *chyle*, which is in reality the nutritious portion eliminated from the food. The chyme thus mixed with chyle arrives in the small intestines; on the walls of which a series of exquisitely delicate vessels ramify in every direction. These vessels absorb or take up the chyle, leaving the rest of the mass to be ejected from the body. The chyle, thus taken up, is carried into little bodies or glands, where it is still further elaborated, acquiring additional nutritious properties; after which, corresponding vessels, emerging from these glands, carry along the fluid to a comparatively large vessel, called the thoracic duct, which ascends in the abdomen along the side of the back-bone, and pours it into that side of the heart to which the blood that has already circulated through the body returns. Here the chyle is intimately mixed with the blood, which fluid is now propelled into the lungs, where it undergoes, from being exposed to the action of the air we breathe, the changes necessary to render it again fit for circulation. It is in the lungs, therefore, that the process of digestion is completed;

the blood has now acquired those nutritious properties from which it secretes the new particles of matter adapted to supply the waste of the different textures of the body.

When food is received into the stomach, the secretion of the gastric juice immediately commences; and when a full meal has been taken, this secretion generally lasts for about an hour. It is a law of vital action, that when any living organ is called into play, there is immediately an increased flow of blood and nervous energy towards it. The stomach, while secreting the bile, displays this phenomenon, and the consequence is that the blood and nervous energy are called away from other organs. This is the cause of that chilliness at the extremities which we often feel after eating heartily. So great is the demand which the stomach thus makes upon the rest of the system, that, during and for some time after a meal, we are not in a condition to take strong exercise of any kind. Both body and mind are inactive and languid. They are so, simply because that which supports muscular and mental activity is concentrated for the time upon the organs of digestion. This is an arrangement of nature which a regard to health requires that we should not interfere with. *We should indulge in the muscular and mental repose which is demanded; and this should last for not much less than an hour after every meal.* In that time, the secretion of bile is nearly finished; the new nutriment begins to tell upon the general circulation; and we are again fit for active exertion. The consequence of not observing this rule, is very hurtful. Strong exercise, or mental application, during or immediately after a meal, diverts the flow of nervous energy and of blood to the stomach, and the process of digestion is necessarily retarded or stopped. Confusion is thus introduced into the system, and a tendency to the terrible calamity of dyspepsia is perhaps established.

For the same reason that repose is required after a meal, it is necessary, in some measure, for a little while before. At the moment when we have concluded a severe muscular task, such, for example, as a long walk, the flow of nervous energy and of circulation is strongly directed to the muscular system. It requires some time to allow this flow to stop and subside; and, till this takes place, it is not proper to bring the stomach into exercise, as the demand which it makes when filled would not in that case be answered. Just so, if we be engaged in close mental application, the nervous energy and circulation being in that case directed to the brain, it is not right all at once to call another and distant organ into play; some time is required to allow of the energy and circulation being prepared to take the new direction. It may, therefore, be laid down as a maxim, that *a short period of repose, or at least of very light occupation, should be allowed before every meal.*

It is remarkable that these rules, although the natural reasons for them were not, perhaps, well known, have long been followed with regard to animals upon which man sets a value, while as yet their application to the human constitution is thought of only by a few. Those intrusted with horses and dogs will not allow them to feed immediately after exercise; nor will they allow them to be subjected to exercise for some time after feeding. Experience has also instructed veteran soldiers not to dine the instant that a long march has been concluded, but to wait coolly till ample time has been allowed for all the proper preparations.

Although strong mental and muscular exercise should be avoided before, during, and immediately after a meal, there can be no objection to the light and lively chat which generally is indulged in where several are met to eat together. On the contrary, it is believed that jocund conversation is useful towards the process of nutrition. Dr Combe, in one of his invaluable works, observes as follows:—"The necessary churning, or agitation of the food, is, from the peculiar situation of the stomach, greatly assisted by the play of the diaphragm

and abdominal muscles during inspiration and expiration; and the diminution of the vivacity and extent of the respiratory movement which always attends despondency and grief, is one source of the enfeebled digestion which notoriously accompanies depression of mind. The same cause also leads necessarily to an unfavourable condition of the blood itself, which in its turn weakens digestion in common with every other function; but the muscular or mechanical influence is that which at present chiefly concerns us. On the other hand, the active and energetic respiration attendant on cheerfulness and buoyancy of spirits, adds to the power of digestion, both by aiding the motions of the stomach and by imparting to it a more richly constituted blood. If to these causes be added the increase of nervous stimulus which pleasing emotions occasion in the stomach (as in the muscles and organs of secretion generally), we shall have no difficulty in perceiving why digestion goes on so well in parties where there is much jocularity and mirth. 'Laughter,' says Professor Hufeland of Berlin, 'is one of the greatest helps to digestion with which I am acquainted; and the custom prevalent among our forefathers, of exciting it at table by jesters and buffoons, was founded on [accidentally in harmony with ?] true medical principles. In a word, endeavour to have cheerful and merry companions at your meals: what nourishment one receives amidst mirth and jollity, will certainly produce good and light blood.'"

KINDS OF FOOD.

It has been shown, by a reference to the structure of the human intestinal canal, that our food is designed to be a mixture of animal and vegetable substances. There is, it is to be remarked, a power of adaptation in nature, by which individuals may be enabled for a considerable time to live healthily on one or the other kind exclusively, or nearly so. The above is, nevertheless, the general rule, to which it is safest to adhere. It has been found, for instance, that field-labourers, including ploughmen, will live healthily for many years on a diet chiefly farinaceous—that is, composed of the farina of grain. But it is to be feared that the food in this case, though apparently sufficient for health, is only so apparently; and that the constitution, being all the time not supported as it ought to be, breaks down prematurely in a great proportion of instances. It has been said, again, that the Irish labouring classes are a remarkably robust race, although their food consists almost exclusively of potatoes. The fact is overlooked, that the Irish eat a quantity of potatoes so enormous, as could not fail to make up in some measure for the want of animal diet. It was found by the Poor-Law Commissioners, that the greater number of the peasantry of Ireland, women as well as men, take at their two daily meals, in general, about nine pounds weight of this food! Such a case is rather to be ranked amongst instances of extraordinary adaptations to a particular kind of food, than as a proof that an unmixed potato diet is healthy. Climate has a remarkable effect in modifying the rule as to a mixture of animal and vegetable food. The former has most of a stimulating quality, and this quality is greater in beef, and flesh in general, than in fowl or fish. Now, the inhabitants of torrid countries are in their ordinary condition least in need of stimulus: hence they find a simple diet of rice and sago sufficient for them. Those, on the contrary, who dwell in cold countries need much stimulus; hence they can devour vast quantities of flesh and blubber, with scarcely any mixture of vegetable food.

Inquiries with respect to the comparative digestibility of different kinds of food, are perhaps chiefly of consequence to those in whom health has already been lost. To the sound and healthy, it is comparatively of little consequence what kind of food is taken, provided that some variation is observed, and no excess com-

* The Physiology of Digestion. By Dr Andrew Combe. Edinburgh: 1836.

mitted as to quantity. Within the range of fish, flesh, and fowl, there is ample scope for a safe choice. There is scarcely any of the familiar aliments of these kinds, but, if plainly dressed, will digest in from two to four hours, and prove perfectly healthy. One rule alone has been pretty well ascertained, with respect to animal foods, that they are the more digestible the more minute and tender the fibre may be. They contain more nutriment in a given bulk than vegetable matters, and hence their less need for length of intestine to digest them. Yet it is worthy of notice, that between the chyle produced from animal and that from vegetable food, no essential distinction can be observed.

Tendon, suet, and oily matters in general, are considerably less digestible than the ordinary fibre; and these are aliments which should be taken sparingly. Pickling, from its effect in hardening the fibre, diminishes the digestibility of meat. Dressed shellfish, cheese, and some other animal foods, are avoided by many as not sufficiently digestible.

Farinaceous foods of all kinds—wheat, oatmeal, and barley bread, oatmeal porridge, sago, arrow-root, tapioca, and potatoes—are highly suitable to the human constitution. They generally require under two hours for digestion, or about half the time of a full mixed meal. The cottage children of Scotland, reared exclusively upon oatmeal porridge and bread, with potatoes and milk, may be cited as a remarkable example of a class of human beings possessing in an uncommon degree the blessing of health. Green vegetables and fruit, however softened by dressing, are less digestible, and less healthy as a diet. One important consideration here occurs. There is need for a certain bulk in our ordinary food. Receiving nutriment in a condensed form and in a small space will not serve the purpose. This is because the organs of digestion are calculated for receiving our food nearly in the condition in which nature presents it, namely, in a considerable bulk with regard to its nutritious properties. The same law applies with respect to the lower animals. When a horse is fed upon corn alone, it does not thrive. Nature did not contemplate that all horses should readily obtain a corn diet, but looked chiefly to grass and hay for their support. She therefore prepared the organs for the reception of something of considerable volume; and when a food of less volume is persisted in, her law is violated, and fatal consequences ensue. Civilised man is apt to pay little attention to this rule in his own case. Consulting taste alone, he is apt to refine his food overmuch, and reject what it were better for him to take. The present writer is much inclined to doubt the propriety of grinding off the coarse exterior of wheaten grain. It does not seem by any means likely that nature calculated the human alimentary cavity for the use of the white interior of the grain, exclusive of all the rest. Wheat forms so large a part of our daily food, that, if this be the case, we unquestionably make a departure of a very important kind from the laws of health. Experience is favourable to this view, for the effect of coarse bread in relaxing seems only comparable to that of white bread in constipating the bowels.

QUANTITY OF FOOD.—NUMBER AND TIMES OF MEALS.

With respect to the amount of food necessary for health, it is difficult to lay down any rule, as different quantities are safe with different individuals, according to their sex, age, activity of life, and some other conditions. There is a general and probably well-founded opinion, that most persons who have the means eat too much, and thereby injure their health. This may be true, and yet it may not be easy to assign to such persons a limit beyond which they ought not to go.

The best authorities are obliged to refer the matter to our own sensations. Dr Beaumont, for example, says that we should not eat till the mind has a sense of *satiety*, for appetite may exceed the power of digestion, and generally does so, particularly in invalids; but to a point previous to that, which “may be known by the

pleasurable sensations of *perfect satisfaction, ease, and quiescence of body and mind.*”

The number and times of meals are other questions as yet undetermined. As the digestion of a meal rarely requires more than four hours, and the waking part of a day is about sixteen, it seems unavoidable that at least three meals be taken, though it may be proper that one, if not two of these, be comparatively of a light nature. Breakfast, dinner, and tea as a light meal, may be considered as a safe, if not a very accurate, prescription for the daily food of a healthy person. Certainly four good meals a-day is too much. No experiments, as far as we are aware, have been made with regard to the total amount of solids which a healthy person in active life may safely take in a day. It has been found, however, that confined criminals and paupers are healthiest when the daily solids are not much either above or below twenty-four ounces.* Of course, in active life there must be need for a larger allowance, but only to a small extent. We may thus arrive at a tolerably clear conviction of the reality of that excess which is said to be generally indulged in; for certainly most grown people who have the means, not excepting many who pursue very sedentary lives, eat much more than twenty-four ounces.

The interval between rising and breakfast ought not to be great, and no severe exercise or task-work of any kind should be undergone during this interval. There is a general prepossession to the contrary, arising probably from the feeling of freedom and lightness which most people feel at that period of the day, and which seems to them as indicating a preparedness for exertion. But this feeling, perhaps, only arises from a sense of relief from that oppression of food under which much of the rest of the day is spent. It is quite inconsistent with all we know of the physiology of aliment, to suppose that the body is capable of much exertion when the stomach has been for several hours quite empty. We have known many persons take long walks before breakfast, under an impression that they were doing something extremely favourable to health. Others we have known go through three hours of mental task-work at the same period, believing that they were gaining so much time. But the only observable result was to subtract from the powers of exertion in the middle and latter part of the day. In so far as the practice was contrary to nature, it would likewise of course produce permanent injury. Only a short saunter in the open air, or a very brief application to business or task-work, can be safely indulged in before breakfast.

With regard to the time for either breakfast or dinner, nothing can be said with scientific authority. Dr Combe, who is by no means disposed to take lax or indulgent views with regard to dietary matters, while favourable to an early dinner hour, allows that he has himself changed his hours for both breakfast and dinner, from comparatively early to comparatively late periods, without any perceptible inconvenience. In rural life, it is found convenient to dine not long after the middle of the day; but in cities, where it is necessary to have a long uninterrupted space in the middle of the day for business, a late dinner-hour is scarcely avoidable. In such a case, a slight lunch serves to keep the strength from sinking; and, if dinner is taken not less than five or six hours before bed-time, it is not easy to see how any injurious consequences should follow. The changes that have taken place in meal hours from old times are more apparent than real. The present substantial lunch of fashionable life occurs nearly at the same hour as the Elizabethan dinner, and the present dinner is in all respects except name the same as the supper of those times. The only thing which the physiologist would much insist on is, that, between the two principal meals of the day there should be no long fasts. If the interval be above seven hours, a biscuit should be taken after four of the seven hours have elapsed. When the

* See two papers on food, in Nos. 366 and 368 of *Chambers's Edinburgh Journal*.

interval amounts to nine hours, the lunch should be a little more substantial, but not of animal food, particularly if any has been taken at breakfast. A glass of wine is often added to a biscuit lunch, or wine alone is taken; but neither of these practices can be commended. While a small quantity of bread or biscuit gives real strength, and is quite sufficient for the occasion, wine only gives a stimulus, serving for the time, but making the case worse afterwards.

VARIETY OF FOOD.

A judicious variation of food is not only useful, but important. There are, it is true, some aliments, such as bread, which cannot be varied, and which no one ever wishes to be so. But apart from one or two articles, a certain variation or rotation is much to be desired, and will prove favourable to health. There is a common prepossession respecting *one dish*, which is more spoken of than acted upon. In reality, there is no virtue in this practice, excepting that, if rigidly adhered to, it makes excess nearly impossible, no one being able to eat to satiety of one kind of food. There would be a benefit from both a daily variation of food and eating of more than one dish at a meal, if *moderation were in both cases to be strictly observed*, for the relish to be thus obtained is useful as promotive of the flow of nervous energy to the stomach, exactly in the same manner as cheerfulness is useful. The policy which would make food in any way unpleasant to the taste, is a most mistaken one; for to eat with languor, or against inclination, or with any degree of disgust, is to lose much of the benefit of eating. On the other hand, to cook dishes highly, and provoke appetite by artificial means, are equally reprehensible. Propriety lies in the mean between the two extremes.

BEVERAGES.

The body containing a vast amount of fluids, which are undergoing a perpetual waste, there is a necessity for an occasional supply of liquor of some kind, as well as of solid food. It remains to be considered what is required in the character or nature of this liquor, to make it serve the end consistently with the preservation of health.

It is scarcely necessary to remark how men in all ages, and almost all climes, have indulged in liquors containing a large infusion of alcohol, or how widespread in our own society is the custom of drinking considerable quantities of wine, spirits, and beer, both at meals and on other occasions. Against habits so inveterate it is apt to appear like fanaticism to make any decided objection; yet the investigator of the laws which regulate health is bound to consider above all things how any particular habit bears upon the human constitution, and to state what is the result of his inquiries, however irreconcilable it may be with popular prejudice.

"The primary effect of all distilled and fermented liquors," says Dr Combe, "is to *stimulate the nervous system and quicken the circulation.*" They may thus be said to have a larger measure of the effect which animal food has upon the system. It is therefore the less surprising that those tropical nations which live most on farinaceous diet, are also found to be those which have the least propensity to the drinking of ardent spirits; while those northern nations which live most on animal food, have the exactly contrary inclination with respect to liquor, the Scandinavian tribes being notoriously the greatest sots that have ever been known. Dr Combe admits that, in some conditions of the system, when the natural stimulus is defective, it may be proper to take an artificial supply in the form of ardent and fermented liquors. "There are," he says, "many constitutions so inherently defective in energy, as to derive benefit from a moderate daily allowance of wine; and there are many situations in which even the healthiest derive additional security from its occasional use. If, for example, a healthy person is exposed to unusual and continued exertion in

the open air, or to the influence of anxious and depressing watchfulness, a moderate quantity of wine with his food may become the means of warding off actual disease, and enabling him to bear up uninjured, where without it he would have given way." But Dr Combe at the same time declares, in the most decided language, that, when the digestion is good and the system in full vigour, the bodily energy is easily sustained by nutritious food, and "artificial stimulant *only increases the wasting of the natural strength.*" Nearly all physicians, indeed, concur in representing ardent liquors as unfavourable to the health of the healthy, and as being, in their excess, highly injurious. Even the specious defence which has been set up for their use, on the ground that they would not have been given to man if they had not been designed for general use, has been shown to be ill-founded, seeing that *vinous fermentation*, from which they are derived, is not a healthy condition of vegetable matter, but a stage in its progress to decay. Upon the whole, there can be little doubt that these liquors are deleterious in our ordinary healthy condition; and that simple water, toast water, whey, ginger beer, or lemonade, would be preferable (the first being the most natural and the best of all), if we could only consent to deny ourselves further indulgence.

CLEANLINESS.

To keep the body in a cleanly condition is the third important requisite for health. This becomes necessary in consequence of a very important process which is constantly going on near and upon the surface of the body.

The process in question is that of *perspiration*. The matter here concerned is a watery secretion produced by glands near the surface of the body, and sent up through the skin by channels imperceptibly minute and wonderfully numerous. From one to two pounds of this secretion is believed to exude through these channels or *pores* in the course of twenty-four hours, being in fact the chief form taken by what is called the waste of the system, the remainder passing off by the bowels, kidneys, and lungs. To promote the free egress of this fluid is of great consequence to health; for when it is suppressed, disease is apt to fall upon some of the other organs concerned in the discharge of waste.

One of the most notable checks which perspiration experiences is that produced by a current of cold air upon the skin, in which case the pores instantly contract and close, and the individual is seized with some ailment either in one of the other organs of waste, whichever is in him the weakest, or in the internal lining of some part of the body, all of which is sympathetic with the condition of the skin. A result of the nature of that last described is usually recognised as a cold or catarrh. We are not at present called on particularly to notice such effects of checked perspiration, but others of a less immediately hurtful or dangerous nature.

The fluid alluded to is composed, besides water, of certain salts and animal matters, which, being solid, do not pass away in vapour, as does the watery part of the compound, but rest on the surface where they have been discharged. There, if not removed by some artificial means, they form a layer of hard stuff, and unavoidably impede the egress of the current perspiration. By cleanliness is merely meant the taking proper means to prevent this or any other matter accumulating on the surface, to the production of certain hurtful consequences.

Ablution or washing is the best means of attaining this end; and accordingly it is well for us to wash or bathe the body very frequently. Many leave by far the greater part of their bodies unwashed, except, perhaps, on rare occasions, thinking it enough if the parts exposed to common view be in decent trim. If the object of cleaning were solely to preserve fair appearances, this might be sufficient; but the great end, it must be clearly seen,

is to keep the skin in a fit state for its peculiar and very important functions. Frequent change of the clothing next to the skin is of course a great aid to cleanliness, and may partly be esteemed as a substitute for bathing, seeing that the clothes absorb much of the impurities, and, when changed, may be said to carry these off. But still this will not serve the end nearly so well as frequent ablution of the whole person. Any one will be convinced of this, who goes into a bath, and uses the flesh-brush in cleansing his body. The quantity of scurf and impurity which he will then remove, from even a body which has changes of linen once a-day, will surprise him.

Considering the importance of personal cleanliness for health, it becomes a great duty of municipal rulers to afford every encouragement in their power to the establishment of public baths for the middle and working classes, and to extend and protect all existing facilities for washing clothes, as well as for private supplies of water. Baths should neither be very cold nor very warm, but in an agreeable medium; and they should never be taken within three hours of a meal. Nature may be said to make a strong pleading for their more general use, in the remarkably pleasing feeling which is experienced in the skin after ablution.

EXERCISE.

The constitution of external nature shows that man was destined for an active existence, as, without labour, scarcely any of the gifts of Providence are to be made available. In perfect harmony with this character of the material world, he has been furnished with a muscular and mental system, constructed on the principle of being fitted for exertion, and requiring exertion for a healthy existence. Formed as he is, it is not possible for him to abstain from exertion without very hurtful consequences.

MUSCULAR EXERCISE.

With regard to merely bodily exercise, it is to be observed, in the first place, that we have no fewer than four hundred muscles, each designed to serve some particular end in locomotion or in operating upon external objects. A sound state of body depends very much upon each of these muscles being brought into action in proper circumstances and to a suitable extent. There is even a law operating within a certain range, by which each muscle will gain in strength and soundness by being brought into a proper degree of activity.

The process of waste and renovation may be said to be always going on in the body, but it does not go on with permanent steadiness unless the muscular system be exercised. Whenever one of the organs is put into exertion, this process becomes active, and the two operations of which it consists maintain a due proportion to each other. A greater flow of blood and of nervous energy is sent to the organ, and this continues as long as it is kept in activity. When one state of action follows close upon another, the renovating part of the process rather exceeds the waste, and an accretion of new substance, as well as an addition of fresh power, takes place. On the contrary, when an organ is little exercised, the process of renovation goes on languidly, and to a less extent than that of waste, and the parts consequently become flabby, shrunken, and weak. Even the bones are subject to the same laws. If these be duly exercised in their business of administering to motion, the vessels which pervade them are fed more actively with blood, and they increase in dimensions, solidity, and strength. If they be little exercised, the stimulus required for the supply of blood to them becomes insufficient; imperfect nutrition takes place; and the consequences are debility, softness, and unfitness for their office. Bones may be so much softened by inaction, as to become susceptible of being cut by a knife. In a less degree, the same cause will produce languor and bad health.

It is of the utmost importance to observe, that the

exercise of any particular limb does little besides improving the strength of that limb; and that, in order to increase our general strength, the whole frame must be brought into exercise. The blacksmith, by wielding his hammer, increases the muscular volume and strength of his right arm only, or, if the rest of his body derives any advantage from his exercise, it is through the general movement which the wielding of a hammer occasions. One whose profession consists in dancing or leaping, for the same reason, chiefly improves the muscles of his legs. The right hands of most persons, by being more frequently employed than the left, become sensibly larger as well as stronger. A still more striking illustration of the principle is to be found in a personal peculiarity which has been remarked in the inhabitants of Paris. Owing to the uneven nature of the pavement of that city, the people are obliged to walk in a tripping manner on the front of their feet; a movement which calls the muscles of the calves of the legs into strong exertion. It is accordingly remarked, that a larger proportion of the people of Paris are distinguished by an uncommon bulk in this part of their persons, than in other cities.

In order, then, to maintain in a sound state the energies which nature has given us, and, still more particularly, to increase their amount, *we must exercise them*. If we desire to have a strong limb, we must exercise that limb; if we desire that the whole of our frame should be sound and strong, we must exercise the whole of our frame. It is mainly by these means that health and strength are to be preserved and improved. There are rules, however, for the application of these laws of our being.

1. In order that exercise may be truly advantageous, the parts must be in a state of sufficient health to endure the exertion. A system weakened by disease or long inaction must be exercised very sparingly, and brought on to greater efforts very gradually; otherwise the usual effects of over-exercise will follow. In no case must exercise be carried beyond what the parts are capable of bearing with ease; otherwise a loss of energy, instead of a gain, will be the consequence.

2. Exercise, to be efficacious even in a healthy subject, must be excited, sustained, and directed by that nervous stimulus which gives the muscles the principal part of their strength, and contributes so much to the nutrition of parts in a state of activity. To explain this, it must be mentioned that to produce motion requires the co-operation of the muscular fibre with two sets of nerves, one of which conveys the command of the brain to the muscle, and causes its contraction, while the other conveys back to the brain the peculiar sense of the state of the muscle, by which we judge of the fitness of the degree of contraction which has been produced to accomplish the end desired, and which is obviously an indispensable piece of information to the mind in regulating the movements of the body. The nervous stimulus thus created, will enable a muscle in the living frame to bear a weight of a hundred pounds, while, if detached, it would be torn asunder by one of ten. It is what causes men in danger, or in the pursuit of some eagerly desired object, to perform such extraordinary feats of strength and activity. In order, then, to obtain the advantage of this powerful agent, *we must be interested in what we are doing*. A sport that calls up the mental energy, a walk towards a place which we are anxious to reach, or even an exercise which we engage in through a desire of invigorating our health and strength, will prove beneficial, when more of actual motion, performed languidly, may be nearly ineffectual.

3. The waste occasioned by exercise must be duly replaced by food; as, if there be any deficiency in that important requisite, the blood will soon cease to give that invigoration to the parts upon which increased health and strength depend.

KINDS OF BODILY EXERCISE.

Exercise is usually considered as of two kinds—active and passive. The active consists in walking, running,

leaping, riding, fencing, rowing, skating, swimming, dancing, and various exercises, such as those with the poles, ropes, &c., prescribed in gymnastic institutions. The passive consists in carriage-riding, sailing, friction, swinging, &c.

Walking is perhaps the readiest mode of taking exercise, and the one most extensively resorted to. If it brought the upper part of the body as thoroughly into exertion as the lower, it would be perfect, for it is gentle and safe with nearly all except the much debilitated. To render it the more effectual in the upper part of the body, it were well to walk at all times, when convenient, *singly*, and allow the arms and trunk free play. It is best to walk with a companion, or for some definite object, as the flow of nervous energy will be by these means promoted, and the exercise be rendered, as has been already explained, the more serviceable.

Very long or rapid walks should not be attempted by individuals of sedentary habits, nor by weakly persons. Their frames are totally unprepared for such violent exertion. When a person who has been long confined at still employments finds himself at liberty to indulge his inclination for a ramble of a few days in the country, he should begin with slow and short marches, and be content therewith till his body is hardened for greater efforts. This is a rule followed in the army with respect to regiments which are about to undertake long marches. Every summer, many youths, from ignorance, do themselves great injury by undertaking pedestrian excursions much beyond their strength. Jaded to the last degree, and incapable of enjoying any thing presented to their observation, they nevertheless persist in making out some appointed number of miles per day, never once thinking of the outrage they are committing upon themselves, and only looking to the glory of executing their task, the only pleasure they find in the journey. Serious consequences—consumption not unfrequently—follow such ill-advised efforts.

With respect to very rapid walking, Dr Johnson records some effects from it, of a remarkable nature, as occurring in his own case. "In my own person," says he, "I had some years ago a very severe and alarming instance of the bad effects of too great muscular action, occasioned by a habit of walking very fast. After a day and night of unusual fatigue and rapid pedestrian exertion, together with considerable mental anxiety, I was suddenly seized with an intermission of the pulse at irregular periods. During each intermission, I felt the heart give a kind of struggle, as it were, and strike with great violence against the ribs, accompanied by a peculiar and most distressing sensation in the cardiac region, which I cannot describe." These symptoms became aggravated, and lasted for eight weeks, "during which time," he continues, "I used horse-exercise, and kept, when at home, in a horizontal position. At length the heart gradually lost its morbid irritability; and at the end of fourteen or fifteen weeks I could walk as well as ever."

Running is an exercise which is intermediate between walking and leaping; it consists, in fact, of a series of leaps performed in progression from one foot to another, and the degree of its rapidity bears a constant proportion to the length of the individual and successive leaps. During this exercise the individual is obliged to take long inspirations, and make slow expirations; the air-cells of the lungs are thereby distended, and the action of the heart being at the same time increased, and the circulation through the lungs much accelerated, a sense of oppression is felt on the chest, which is often exceedingly painful; when the violent action is discontinued, the heart palpitates with intermitting strokes, in the endeavour to recover its natural equilibrium of motion. Although this and other gymnastic exercises, such as leaping, wrestling, throwing heavy weights, &c., may, when judiciously had recourse to, invigorate the body, yet, from apprehension of the evils and accidents which may be so occasioned, young persons ought not to be permitted to engage extensively in such exer-

cises, except under the care of some one well acquainted with gymnastics.

Fencing is of all active exercises that which is the most commendable, inasmuch as it throws open the chest, and at the same time calls into action the muscles both of the upper and lower extremities. Add to this that it improves very much the carriage of the body; for which reason it may be reckoned a branch of polite education. The salutary effects of the other exercises which are taught in gymnastic institutions, such as exercise with the ropes, poles, pulleys, &c., in increasing the strength of the body, will be seen by consulting Mr Roland's Treatise on Gymnastics, where will be found a table showing the amount of the increasing growth and strength of the body in a given time, during the employment of these exercises.

Dancing is exhilarating and healthful, and seems to be almost the only active exercise which the despotic laws of fashion permit young ladies to enjoy. We can scarcely consider modern quadrilles, elegant though they be, as exercise, seeing that they differ little from the most common walking movement. But country-dances, reels, and hornpipes, are genuine exercise, and their less refinement may be considered as amply compensated by the superior benefit which they confer upon health.

Riding is generally classed among the passive exercises, but in reality it is one which involves much action of the whole frame, and as such is very useful for health. Pursued solitarily, it has the drawback of being somewhat dull; but, when two or three ride in company, a sufficient flow of the nervous energy may be obtained.

The amount of bodily exercise which should be taken must vary according to the habits, strength, and general health of the individual. It was an aphorism of Boerhaave, that every person should take at least two hours' exercise in the day, and this may be regarded as a good general rule.

MENTAL EXERCISE.

Having thus explained the laws and regulations by which exercise may be serviceable to the physical system, we shall proceed to show that the same rules hold good respecting the mental faculties. These, as is generally allowed, however immaterial in one sense, are connected organically with the brain—a portion of the animal system nourished by the same blood, and regulated by the same vital laws, as the muscles, bones, and nerves. As, by disuse, muscle becomes emaciated, bone softens, blood-vessels are obliterated, and nerves lose their natural structure, so, by disuse, does the brain fall out of its proper state, and create misery to its possessor; and as, by over-exertion, the waste of the animal system exceeds the supply, and debility and unsoundness are produced, so, by over-exertion, are the functions of the brain liable to be deranged and destroyed. The processes are physiologically the same, and the effects bear an exact relation to each other. As with the bodily powers, the mental are to be increased in magnitude and energy by a degree of exercise measured with a just regard to their ordinary health and native or habitual energies. Corresponding, moreover, to the influence which the mind has in giving the nervous stimulus so useful in bodily exercise, is the dependence of the mind upon the body for supplies of healthy nutriment. And, in like manner with the bodily functions, each mental faculty is only to be strengthened by the exercise of itself in particular. Every part of our intellectual and moral nature, stands, in this respect, exactly in the same situation with the blacksmith's right arm and the lower limbs of the inhabitants of Paris: each must be exercised for its own sake.

The fatal effects of the disuse of the mental faculties are strikingly observable in persons who have the misfortune to be solitarily confined, many of whom become insane, or at least weak in their intellects. It is also observable in the deaf and blind, among whom, from the non-employment of a number of the faculties, weakness of mind and idiocy are more prevalent than among

other people. This is indeed a frequent predisposing cause of every form of nervous disease.

The loss of power and health of mind from imperfect or partial exercise of the faculties, is frequently observable in the country clergy, in retired merchants, in annuitants, in the clerks of public offices, and in tradesmen whose professions comprehend a very limited range of objects. There is no class, however, in whom the evil is more widely observable than in those females, who, either from ignorance of the laws of exercise, or from inveterate habit, spend their lives in unbroken seclusion, and in the performance of a limited range of duties. All motive is there wanting. No immediate object of solicitude ever presents itself. Fixing their thoughts entirely on themselves, and constantly brooding over a few narrow and trivial ideas, they at length approach a state little removed from insanity, or are only saved from that, perhaps, by the false and deluding relief afforded by stimulating liquors. In general, the education of such persons has given them only a few *accomplishments*, calculated to afford employment to one or two of the minor powers of the mind, while all that could have engaged the reflecting powers has been omitted. Education, if properly conducted, would go far to prevent the evils which befall this unfortunate part of the community.

On the other hand, excessive exercise of the brain, by propelling too much blood to it, and unduly distending the vessels, is equally injurious with its disuse. And not only are fatal effects to be apprehended from undue mental task-work, but also from that constant *stretch* of the mind which attends an unduly anxious and watchful disposition. The ancients had some notion of the impropriety of an incessant exertion of the mind, and rebuked it by their well-known proverb—*Apollo does not keep his bow always bent*. But they had comparatively little experience of the oppressive mental labours endured by large portions of modern society. Irrational, and in some respects dangerous, as many of the habits of our ancestors were, it is questionable if they suffered so much from these causes as their successors do from virtuous but overtaking exertion. To maintain what each man conceives to be a creditable existence, now requires such close and vigorous exertions, that more, we verily believe, perish in the performance of duties in themselves laudable, than formerly sank under fox-hunting, toast-drinking, and the gout.

It is in large cities that this unintentional kind of self-destruction is most conspicuously exemplified. And it is in London, above all other places, that the frenzy is to be observed in its most glaring forms. To spend nine hours at a time in business, without food or relaxation, is not only not uncommon, but an almost universal practice, among the citizens of London: from a breakfast at eight to a chop at five, they are never, to use an expressive phrase, *off the stretch*. Upon a stomach enfeebled by exhaustion, they then lay the load of a full meal, which perfect leisure would hardly enable them to digest. But, far from waiting to digest it, they have no sooner laid down knife and fork, than away they must once more rush to business—not perhaps willingly, for nature tells them that it would be agreeable to rest; but then—but then business *must* be attended to. If nature were to punish the daily transgression by the nightly suffering, we should find few who, for the sake of pecuniary gain, would thus expose themselves to misery. But, unfortunately, she runs long accounts with her children, and, like a cheating attorney, seldom renders her bill till the whole subject of litigation has been eaten up. Paralysis at fifty comes like the mesne process upon the victim of commercial enthusiasm,* and either hurries him off to that prison from which there is no liberation, or leaves him for a few years organically alive to *enjoy* the fruits of his labours. A life thus spent is a mere fragment

of what it ought to be. The means of obtaining pleasure have swallowed up the end. The glorious face of nature, with all its sublime and beautiful alternations; the delights of social life; the pleasures arising from the exercise of the finer feelings and the cultivation of the intellect; all that higher class of gratifications which nature has designed a moderate labour to place within the reach of *all* her creatures, have been lost to such a man.

The absurdity of an ignorance or weakness of this kind is perhaps still more striking, when it occurs in individuals who make the acquisition of knowledge the chief aim of life. As the world is at present situated, it is possible to acquire learning upon almost every subject, and an infinite amount of knowledge, useful and otherwise, without even by chance lighting upon a knowledge of the most indispensable observances necessary for the preservation of a sound mind in a sound body. Half of the multifarious languages of Asia may be mastered, while the prodigy who boasts so much learning knows not that to sit a whole day within doors at close study is detrimental to health; or, if he knows so much, deliberately prefers the course which leads to ruin. Leyden, an enthusiast of this order, was ill with a fever and liver complaint at Mysore, and yet continued to study ten hours a-day. He eventually sank, in his thirty-sixth year, under the consequences of spending some time in an ill-ventilated library, which a slight acquaintance with one of the most familiar of the sciences would have warned him against entering. Alexander Nicoll, a recent professor of Hebrew at Oxford, of whom it was said that he might have walked to the wall of China without the aid of an interpreter, died at the same age, partly through the effects of that intense study which so effectually but so uselessly had gained him distinction. Dr Alexander Murray, a similar prodigy, died in his thirty-eighth year, of over-severe study; making the third of a set of men remarkable for the same wonderful attainments, and natives of the same country, who, within a space of twenty years, fell victims to their ignorance of the laws of mental exercise. In 1807, Sir Humphry Davy prosecuted his inquiry into the alkaline metals with such inordinate eagerness, that, through excitement and fatigue, he contracted a dangerous fever, which he, in ignorance of the human physiology, ascribed to contagion caught in experimenting on the fumigation of hospitals. His physician was at no loss to trace it to his habits of study, which were such as would have soon worn out a frame much more robust. Davy at this time spent all the earlier part of the day in his laboratory, surrounded by persons of every rank, whose admiration of his experiments added to his excitement. Individuals of the highest distinction “contended for the honour of his company to dinner, and he did not possess sufficient resolution to resist the gratification thus afforded, though it generally happened that his pursuits in the laboratory were not suspended until the appointed dinner hour had passed. On his return in the evening, he resumed his chemical labours, and commonly continued them till three or four in the morning, and yet the servants of the establishment not unfrequently found that he had risen before them.”* Over-tasked nature at length yielded under his exertions, and it was with the greatest difficulty that he was restored to health. Excessive application is known to have in like manner thrown Boerhaave into a species of delirium for six weeks, and to have on one occasion given a severe shock to the health of Newton. It unquestionably cut short the days of Sir Walter Scott, and also of the celebrated Weber, whose mournful exclamation in the midst of his numerous engagements can never be forgotten:—“Would that I were a tailor, for then I should have a Sunday’s holiday!”

The premature extinction of early prodigies of genius is generally traceable to the same cause. We read that, while all other children played, they remained at home to study; and then we learn that they perished in the

* Paris’s Life of Sir Humphry Davy, p. 183.

* Of the frequent occurrence of premature paralysis, in consequence of the mode of life above described, we are assured by a metropolitan physician of the greatest eminence.

bud, and balked the hopes of all their admiring friends. The ignorant wonder is of course always the greater, when life is broken short in the midst of honourable undertakings. We wonder at the inscrutable decrees which permit the idle and the dissolute to live, and remove the ardent benefactor of his kind, the hope of parents, the virtuous and the self-devoted; never reflecting that the highest moral and intellectual qualities avail nothing in repairing or warding off a decided injury to the physical system, which is regulated by different laws. The conduct of the Portuguese sailors in a storm, when, instead of working the vessel properly, they employ themselves in paying vows to their saints, is just as rational as most of the notions which prevail on this subject in the most enlightened circles of British society.

It ought to be universally known, that the uses of our intellectual nature are not to be properly realised without a just regard to the laws of that perishable frame with which it is connected; that, in cultivating the mind, we must neither overtask nor undertake the body, neither push it to too great a speed, nor leave it neglected; and that, notwithstanding this intimate connexion and mutual dependence, the highest merits on the part of the mind will not compensate for muscles mistreated, or soothe a nervous system which severe study has tortured into insanity. To come to detail, it ought to be impressed on all, that to spend more than a moderate number of hours in mental exercise diminishes insensibly the powers of future application, and tends to abbreviate life; that no mental exercise should be attempted immediately after meals, as the processes of thought and of digestion cannot be safely prosecuted together; and that, without a due share of exercise to the whole of the mental faculties, there can be no soundness in any, while the whole corporeal system will give way beneath a severe pressure upon any one in particular. These are truths completely established with physiologists, and upon which it is undeniable that a great portion of human happiness depends.

REPOSE A CONDITION DEMANDED BY EXERCISE.

Exercise demands occasional periods of repose, and, in particular, that a certain part of every twenty-four hours be spent in sleep. After having been engaged in daily occupations for fourteen or sixteen hours, a general feeling of fatigue and weakness is induced; the motions of the body become difficult, the senses confused, the power of volition or *will* suspended, and the rest of the mental faculties, becoming more and more inactive, sink at length into a state of unconsciousness. The sense of sight first ceases to act by the closing of the eyelids; then the senses of taste and smell become dormant; and then those of hearing and touch. The muscles, also, dispose themselves with a certain reference to ease of position, those of the limbs having grown indolent before those that support the head, and those that support the head before those of the trunk. In proportion as these phenomena proceed, the respiration becomes slower and more deep, the circulation diminishes in impetus, the blood proceeds in great quantity towards the head, and all the functions of the internal organs become retarded. In this state, shut out, as it were, from the external world, the mind still retains its wonted activity, deprived, however, of the guidance of judgment and the power of *distinct* recollection; in consequence of which, it does not perceive the monstrous incongruities of the imagery which sweeps before it, and takes but faint cognisance of the time which elapses.

It may be laid down as an axiom, that the more uninterrupted sleep is, the more refreshing and salutary will be its effects; for, during this period, the body undoubtedly acquires an accession of nervous energy, which restlessness, however induced, must disturb; and therefore the state of the body before going to sleep, the kind of bed, and the manner of clothing, require especial attention. As the functions of the body are performed more slowly during our sleeping than our

waking hours, a full meal or supper, taken immediately before going to bed, imposes a load on the stomach which it is not in a condition to digest, and the unpleasant consequence of oppressive and harassing dreams is almost certain to ensue. When the sleeper lies upon his back, the heart pressing, while pulsating, on the lungs, gives rise to a sense of intolerable oppression on the chest, which seems to bear down upon the whole body, so that in this painful state not a muscle will obey the impulse of the will, and every effort to move appears to be altogether unavailing. This constitutes *incubus* or *nightmare*; and it may be observed, that, as acidity on the stomach, or indigestion, gives rise to such dreams, so all dreams of this disturbed character are converse indications of indigestion; for which reason the great physiologist Haller considered dreaming to be a symptom of disease. It is certain that the dreams of healthy persons are the lightest and most evanescent.

The kind of bed on which we repose requires attention. Some are advocates for soft, others for hard beds; hence some accustom themselves to feather-beds, others to mattresses. The only difference between a soft and a hard bed is this—that the weight of the body in a soft bed presses on a larger surface than on a hard bed, and thereby a greater degree of comfort is enjoyed. Parents err in fancying that a very hard bed contributes to harden the constitution of their children; for which reason they lay them down on mattresses, or beds with boarded bottoms. A bed for young children cannot be too soft, provided the child does not sink into it in such a manner that the surrounding parts of the bed bend over and cover the body. The too great hardness of beds, says Dr Darwin, frequently proves injurious to the shape of infants, by causing them to rest on too few parts at a time; it also causes their sleep to be uneasy and unrefreshing. The universal analogy derived from other animals evinces the truth of this doctrine, both in respect to the softness and due degree of warmth of their beds. Birds line the nests of their young with feathers; the eider duck and the rabbit pluck the down from their own breasts to increase the softness of the beds of their tender offspring, and brood over them with their wings, or clasp them to their bosoms, for the sake of warmth. For this reason, it is better that weak children should sleep with a bedfellow than alone; for, in this case, if any part of the body becomes cold, the child instinctively places that part in contact with the warmer body of its companion. So, also, it is better for a new-born infant to sleep with its mother in winter, or with its nurse, than in a solitary crib by the bedside. When in bed, the head should be always higher than the feet, and those subject to palpitation of the heart should lie with their heads very high. Night clothes should never consist of more than a chemise or shirt of cotton or linen, with a flannel shirt beneath. It is also highly improper to sleep in a bed overloaded with clothes; the body is thereby heated, and feverishness and restlessness induced. Accordingly, persons who complain of sleeplessness should look to the quantity of their bed-clothing; for the unnecessary addition of a single blanket may be the sole cause of the annoyance. It is also imprudent to lie with the head entirely within the bed-clothes; for, in this case, the same air which has been already breathed must be again and again inhaled. For the same reason, the curtains should not be drawn closely round the bed. Washing the face and hands, and brushing the teeth, before going to bed, will be found to contribute materially to comfort. Whatever be the time chosen for sleep, it is evident that no person can with impunity convert day into night. Eight o'clock for children, and eleven for adults, may be recommended as good hours for retiring to rest. It is well known that children require more sleep than adults; and more sleep is requisite in winter than in summer. The average duration of sleep which may be recommended for adults is *eight* hours; but much depends upon habit, and many persons require only six. It is scarcely necessary to observe,

that, on rising in the morning, the strictest attention should be paid to washing the face, neck, and hands; the mouth and teeth should also be well cleansed. The most simple powder for the teeth is finely brayed charcoal, a little of which will clear away all impurities, and preserve the teeth. On leaving the bedroom, the windows should be opened, and the clothes of the bed turned down, in order that the exhalations of the body during sleep may be dissipated. If, instead of this, the bed be made immediately after we have risen, these exhalations are again folded up with the clothes—a practice which is not consonant either with cleanliness or health.

TEMPERATURE.

The fifth important requisite for health is that the body be kept in a temperature suitable to it.

The degree of heat indicated by sixty degrees of Fahrenheit's thermometer, or that of a temperate summer day, is what the human body finds it agreeable to be exposed to when in a state of inactivity. In air much colder, the body experiences an unpleasant sensation, unless some warm clothing be worn, or a pretty active exercise be indulged in. When, either by natural or artificial means, the body is kept in a suitable state of warmth, the functions of the circulation and perspiration in the skin go on healthily; it is red, in consequence of the blood being urged into the capillaries or minute vessels near the surface; it is also soft and moist, from the action of the glands for secreting the waste fluid and its free egress through the pores. This is a condition of great comfort, and the appearance of those who enjoy it conveys to others the notion that they are in good health. When, on the contrary, there is a much lower temperature, the functions of the vessels connected with the skin are apt to be considerably deranged. The vessels, in these circumstances, contract; the blood is driven inwards, where it sometimes occasions diseases of a dangerous nature; the perspiration, also, being prevented from passing out by its usual channels, catarrhal complaints ensue, sometimes ending in consumption.

It is of the more importance to make these facts generally known, as a notion prevails that exposure to a painful degree of cold tends to induce hardness of constitution and to promote health. Undoubtedly, there may be harm from an opposite extreme, and we know well that excessive clothing and living in overheated apartments are detrimental to health. But safety lies in a medium between the two extremes. There is a degree of warmth which is both agreeable and healthy, and which it is desirable to have around us as constantly as possible.

There is no period of life at which warmth is of more consequence than in infancy. In a very young babe, the circulation is almost altogether confined to the surface, the internal organs being as yet in a very weak state. In such circumstances, to plunge the child into cold water, from an idea of making it hardy, as is customary in some countries, and among ignorant persons in our own, is the height of cruelty and folly; for the unavoidable consequence is, that the blood is thrown in upon the internal organs, and inflammation, bowel-complaints, croup, or convulsions, are very apt to ensue. A baby requires to be kept at a temperature above what is suitable to a grown person; it should be warmly, but not heavily clothed; the room where it is kept should be maintained at a good, but not oppressive heat; and it should never be put into other than tepid water. It should not be exposed to the open air for some days after its birth.

At all periods of life, it is most desirable to avoid exposure to very low temperatures, especially for any considerable length of time. To sit long in cold school-rooms or work-rooms, with the whole body, and especially the feet, in a chilled condition, is very unfavourable to the health of young people. It is not possible that a condition so adverse to the healthy action of the cuta-

neous vessels, should not lead, if long persisted in, to very bad consequences. Those who are compelled to be sedentary, should make it their endeavour to obtain a sufficiently high temperature, either by warming their apartments sufficiently, or thickening their clothing. Common fires, though delightful from their cheerful look, are confessedly very inadequate, in most circumstances, to heat large work-rooms, school-rooms, or even the larger class of sitting-rooms; not to speak of the great objection which has been made to them on the score of economy, three-fourths of their heat being sent off through the chimney. It is most desirable that some means in which the public could have confidence were devised for thoroughly, and at the same time healthily, warming large apartments. Stoves enclosed in large iron-plate cases (Arnott's stoves), pipes of hot water or of steam, and blasts of heated air, are amongst the most conspicuous plans tried within the last few years. But none of these plans seems to have succeeded in obtaining the hearty approbation of the public, chiefly, we suspect, from their not being accompanied by what is peculiarly necessary where they are in operation, a means of ventilation. We can speak from some experience in favour of the plan of large steam-tubes, accompanied by a ventilating process; and have very little doubt that, with the latter requisite, this and several other of the recently suggested modes of heating might be found to serve the desired end. It is certainly of great consequence that some plan should be generally consented upon for warming the large rooms in which scholars and work-people spend so much time, as the chilliness there so generally experienced is a fatal underminer of the human constitution.

Clothing should be in proportion to the temperature of the climate and the season of the year; and where there are such abrupt transitions from heat to cold as in our country, it is not safe ever to go very thinly clad, as we may in that case be exposed to a sudden chill before we can effect the proper change of dress. Very fatal effects often result to ladies from incautiously stepping out of heated rooms in the imperfect clothing which they ludicrously style *full-dress*: all such injuries might be avoided by putting on a sufficiency of shawls, and allowing themselves a little time in the lobby to cool. The under-clothing in this country should be invariably of flannel, which is remarkably well calculated to preserve uniformity of temperature, as well as to produce a healthy irritation in the skin. While the value of comfortable clothing is fully acknowledged, we should never lose sight of the value of exercise for keeping up a kindly glow upon the surface, and for the support of a high tone of general health. Any one who, neglecting this, should live constantly in a warmed apartment, or only go out of doors muffled up in a load of clothes, would speedily suffer from a relaxed state of the system, and become so susceptible of damage from the slightest change of temperature in the atmosphere, that the most dangerous consequences might be apprehended.

Wet clothes applied to any part of the body, when it is in an inactive state, have an instantaneous effect in reducing the temperature, this being an unavoidable effect of the process of evaporation which then takes place. Hence it is extremely dangerous to sit upon damp ground, or to remain at rest for a single minute with wetted feet, or any other part of the body invested in damp garments. Dampness in the house in which we live has the same effect, and is equally dangerous. The chill produced by the evaporation from the wetted surface, checks the perspiration, and sends the blood inwards to the vital parts, where it tends to produce inflammatory disease. Few persons seem to be aware of these truths. We find young men heedlessly getting their feet wet, and sitting with them in that condition, thereby incurring the most deadly peril. Young women commit a similar folly, when they walk out in thin shoes in a wet or cold day. Exposure to wet, damp, or cold, is of comparatively little moment when the body,

by a course of exercise or training, has been prepared to endure these conditions. Thus, a person brought up delicately, or much within doors, would be killed by that which would have little or no effect on a ploughman. It is therefore worthy of being suggested as a line of policy, that no one should accustom him or herself to a pampered or too delicate mode of life. Every one should, if possible, go out daily, both in good and bad weather, with clothing corresponding to the nature of the weather, and in this way strengthen and harden the constitution to endure all ordinary and reasonable exposure. It is important, however, to note, that even the hardest persons are never safe from the effects of wet clothes and other modes of exposure to a reduced temperature. No complaint is more common among out-of-door labourers, and also poor people in damp lodgings, than rheumatism. This is an affection produced solely by a violation of the natural law which demands that the body should not be chilled. Rheumatism is produced alike from exposure to a shower or to a draught of cold air when the body is warm, and from sitting with the feet on a cold stone or clay floor; the only difference, perhaps, being that the rheumatism is in one case in the shoulders and in the other in the legs. Let us therefore impress on all the propriety of avoiding chills, the effects of which may be much more fatal than a simple attack of rheumatism. When rheumatism has been contracted, the best remedy for its expulsion, if adopted in time, is friction of the part; if well rubbed before a fire with flour of mustard, so as to cause a counter irritation on the surface, the internal complaint may be expelled.

ERRORS IN DRESS.

This is perhaps the most appropriate place in which to introduce some remarks upon errors in dress. The integuments which nature calls upon us to put on for the sake of warmth, are too often made the means of inflicting serious injury, either through ignorance or caprice. It is therefore necessary, in a treatise on the preservation of health, to advert in emphatic terms to this subject.

It is scarcely too much to say, that there is no part of the human frame, from the sole of the foot to the crown of the head, which has not been, and is not at this moment, mistreated by fashion. We laugh at the Chinese ladies, who have their feet constrained by iron moulds into mere bulbous appendages to the limbs; but we never reflect that, amongst ourselves, errors only inferior in degree are constantly committed. The foot naturally spreads out, fan-like, from the heel to the toes. But, instead of having our shoes formed in the same triangular shape, they are made in a lozenge form, truncated at the front, the toes being thus perverted from their radiating arrangement into one exactly the opposite; so that they become crushed under one another, and deprived of a great part of that muscular power by which they were designed to propel our bodies in walking. In the greater height usually given to the heels of shoes, another important deviation from nature is committed. When the heel is raised above the level of the ball of the foot, a complete derangement takes place in the muscles of locomotion; the power of the limb is impaired; and the whole body is thrown off its equipoise. It is impossible in such circumstances to exercise the body as it ought to be. The foot is also forced or plugged down into the narrow front of the shoe, where the toes become liable to the grievance of corns. Thus the free healthy play of the various parts of the body is further diminished. From the uneasiness and constraint experienced in the feet, sympathetic affections of a dangerous kind often assail the stomach and chest; as hemorrhage, apoplexy, and consumption. Low-heeled shoes, with a sufficiency of room for the toes, would completely prevent all such consequences.

An improved taste in the male sex has long since abolished the coarse and self-annoying absurdity of leathern small-clothes; but it is still too common to impede the circulation and the play of the muscles by

tight apparel, especially in the regions of the stomach and neck. The immediate effect of these injudicious appliances is much inconvenience: the remote result is a diminution of the general strength and health. But all the errors of the male sex sink into insignificance, when compared with one to which the fair are liable. In the construction of the human chest, nature has provided ample room for several important viscera, the functions of which cannot be in any degree disturbed without a wrong being inflicted upon the whole system. Here reside the heart, the lungs, the liver, and the stomach. Fine ladies may affect to shut their mind's eye to the existence of such things; but the daintiest of their emotions depend upon the right state of those very viscera, without which they could no more think, speak, and act, than they could cast languishing looks without eyes, or melt our hearts by witching minstrelsy without a tongue and fingers. In the natural state, the external figure at this place tapers gently downwards. The waist of the Venus de Medici is of that form, and its perfect elegance was never challenged. But the women of the ordinary world have set up for themselves a different standard of beauty. A fine waist, in their estimation, is one which tapers rapidly below the arms, and is not above two-thirds of the natural girth. It must also be strictly round, although the waist of nature verges upon the oval. In order to reduce themselves to the desired shape and space, almost all the unmarried, and not a few of those who are otherwise, brace themselves in a greater or less degree with corsets, which no doubt produce the requisite roundness and slenderness, but at the expense of all the internal organs upon which health depends. The false ribs are pressed inwards; the respiratory and circulatory systems are crushed and thrust out of their proper place; the alimentary system is deranged; and even upon the exterior of the person, deformities of the most glaring kind, such as humped shoulders and curved spines, are produced. Custom to a certain extent enables the victim to endure the inconvenience; there are even some who feel so little trouble from it, as to deny that any harm ensues from tight-lacing. But a violation so great cannot be otherwise than mischievous. We have seen a young lady's sash which measured exactly twenty-two inches, showing that the chest to which it was applied had been reduced to a diameter (allowing for clothes) of little more than seven inches. All who are aware of the internal organs at that part, know very well that it is impossible for them to exist in their natural condition within so small a space. Bruised, impeded, and disordered, they must of course be, and accordingly cannot fail to become a source of dreadful suffering to the wretched being who outrages them. Palpitations, flushings, dyspepsia, determination of blood to the head, and consumption, are among the evils which physicians enumerate as flowing from this sacrifice to vanity. Another of a moral kind is acknowledged to be of by no means infrequent occurrence: in order to soothe the painful sensations produced by the constraint, spirituous liquors and cordials are resorted to, and thus habits of the most degrading nature are formed. Another evil still, respecting which a hint may be sufficient, is the unfitting of the system for the duties of a mother. How many domestic afflictions, which are submitted to in a spirit of resignation, as the unavoidable decrees of Providence; how many of the saddest scenes which this world ever presents—gentle and tender girls pining away under the eyes of hopeless parents—beloved wives torn from the arms of husbands and children at the very moment when prolonged life was most needful—must be owing to a cause too trivial and unworthy to be mentioned in the same sentence with its so dire effects! No doubt, it is well to submit meekly to such afflictions; but while they are ascribed in all humility to a Providence which is upon the whole only another term for Mercy and Justice, let us not be blind to the fact that they accrue through violations committed by ourselves upon laws established by Pro-

vidence for our happiness, and might have been avoided by a different course of conduct.

The fashion of tight-lacing obviously owes its origin to a desire on the part of the ladies to attract admiration. It is of little importance to point out that they are quite wrong in their calculations as to the effect; but we would press upon the guilty parties, and all interested in their welfare, that tight-lacing is a practice which cannot be long persisted in without the most disastrous consequences. It is painful to reflect, that parents, so far from discouraging the practice, are so ignorant as often to force it upon their children. We have heard of a young lady whose mother stood over her every morning, with the engine of torture in her hand, and, notwithstanding many remonstrative tears, obliged her to submit to be laced so tightly as almost to stop the power of breathing. The result is, that the unfortunate victim is now severely afflicted with asthma, and has fallen into a state of low health. As a general rule, it cannot be too strongly impressed upon those who have the care of young persons, that all clothing should sit lightly upon the figure, so as to allow of the full play of every part of the system.

INNOCENT ENJOYMENTS.

A sufficiency of innocent enjoyments has been set down as the sixth requisite towards the preservation of health. It may seem almost superfluous to treat this part of the subject, since the disposition to take amusement is one by no means generally wanting. A regard, however, for the completeness of our little treatise enforces us to make a few remarks on it; and we are not satisfied that there is not a considerable number of persons to whom an injunction to take innocent enjoyments is needful. There may be a general advantage in seeing the matter placed on something like a philosophical basis.

No physiological doctrine seems more entitled to faith and regard, than that a harmonious exercise, in moderation, of all parts of the system, including the organs of the mental faculties, is necessary for health. It is proved by the very craving which we experience, after a long task, or a long perseverance in some particular habits, for something which will engage a different set of faculties. There is nothing which will pleasantly engage our thoughts for any considerable length of time. Something inferior will invariably be preferred, if it only be new. Now, the duties by which men in general earn their subsistence, are in all cases of such a nature as only to call into exercise a part of their mental and bodily system. Something is required, at once to soothe and compensate us for the drudgery of our current labours, and to bring into exercise those parts of our muscular frame and intellect, which professional duty has left unoccupied. To begin with an humble illustration: how delightful to a tailor, after long exercising his fingers and arms alone at his business, to enter into some athletic sport upon the village-green, by which his limbs also will be exercised! After a lawyer has fagged for a day at a brief, how delightful to be able, by the reading of a new novel or play, to call up another set of the intellectual powers! In these changes from grave to light occupation, there is at once repose given to the tasked faculty, and the gratification of employment given to others which have been pining for want of something to do. It so happens that, from the sentient nerves being mixed with those which direct the operations of all our organs, each organ has a sense of enjoyment in being rightly exercised. Even the stomach has, from this cause, a gratification when its functions are going on well, and this altogether independent of any pleasure we may have had in eating the meal upon which it is now employed. An organ left long unoccupied is thus somewhat like a child in a family which its parents have been overlooking. It craves to be noticed like the rest, and, when the desired notice at length comes, it experiences a high degree of satisfaction. In short, variation of occupation and pur-

suit, for the purpose of keeping all the parts of the system in harmonious exercise and in healthy tone, is one of the most important principles concerned in the preservation of health.

There are several powers of the mind which must have been designed for the express purpose of creating and receiving amusement, and the existence of which, therefore, shows that amusement has a place in the right economy of human life. The imitative arts in general, music, fiction, drollery of all kinds, spring directly from primitive faculties of the mind; and, when we see the pleasure they give in society, we cannot doubt that they are things naturally required by man, and in which it is quite legitimate for him to indulge within moderate bounds and in circumstances compatible with innocence. These things are doubtless designed to alleviate the burdens of life and beguile us of its cares. They furnish something like a different sphere of existence, into which we may enter and temporarily lose the sense of all that harasses us in the ordinary one. The *joculator*—under which name our ancestors associated the poet, tale-teller, and mimic, and which we may apply equally extensively to the poet, novelist, artist, and player—is therefore a most useful functionary in society. We say nothing on the present occasion of the refinement to be derived, in addition, from communion with the productions of the higher class of such minds.

Amongst amusements, *reading* takes a most distinguished place, for there is none which may be more readily or more innocently indulged in, and fortunately, in our own country, it is one which may now be enjoyed by all. It is unquestionably the chief of in-door amusements; and few scenes are calculated to awaken more agreeable feelings in a well-constituted mind, than a family group assembled in their parlour, to hear some one of their number reading a pleasant book. Ever honoured be the great masters of fiction, who have allowed us, by these means, to pass from common life, for a time, into "the tale of Troy divine," the story of "the gentle lady married to the Moor," the tear-compelling fate of Ravenswood, and all the other numberless suppositions of things done, and persons who spoke and acted, which we feel to be more real than much of even the life that is passing around us!

Next to reading stands *music*, a means of enjoyment of which only a few comparatively, in our country, take advantage, but which might easily be made much more extensively available, and probably will be so in the course of a few years. Connected intimately with music is *dancing*, which is not only a cheerful amusement, but a positive and direct means of bodily exercise. A family musical or dancing scene, like a family reading scene, is a thing beautiful to look upon. There is a prejudice against both in some minds, on account of their being liable to abuse; but the abuses of both arise very much from their not being extensively or freely indulged in. Were music the general accomplishment which it might easily be made, it would not only be indulged in on all occasions with simplicity and innocence, but it would supplant coarser and more clandestine amusements. Dancing is the nightly amusement of the French peasantry, and it has never been pretended that these people are less virtuous than the corresponding class in our own country. *Theatrical representations* it might be more difficult to place on such a footing as to secure the unhesitating approbation of the good; but certainly, if this were done, they might prove highly serviceable in furnishing amusement.

In the class of amusements we must reckon meetings or promenades in ornamental grounds, excursions into the country, and little tours, all of which are highly commendable in those who are able to indulge in them. The entertainment of little parties of friends, and the going out to entertainments given by them in return, are other means of amusement common in society, and which may be moderately indulged in with much advantage. In short, whatever gives a pleasant variation to the monotony of life, without leading the mind away from duty or corrupting the manners, ought to

be indulged in as freely as circumstances will permit. The mind returns from such diversions with renewed tone and power, and neither the time nor the expense is lost in the long run. It is the more necessary to impress these maxims, as many well-meaning persons, alarmed perhaps at the occasional abuse of such enjoyments, repudiate them nearly altogether, and thereby lower the tone of their health, both as respects the body and the mind. It is particularly distressing to see such persons exercising a control over the young, and denying to their unfortunate protégés an element of life not much less pressingly necessary than the air they breathe.

Dr Southwood Smith, in his excellent work "The Philosophy of Health," has pointed out that pleasure is the ordinary, and pain in all cases an extraordinary, result of the action of our organs. "There are," he says, "many cases in which pleasure is manifestly given for its own sake; but in no case is the excitement of pain gratuitous." Pain is always a punishment; and, when it reaches a certain extreme, it is destructive of what feels it. But "all such action of the organs as is productive of pleasure is conducive to the perpetuation of life. There is a close connexion between happiness and longevity. Enjoyment is not only the end of life, but it is the only condition of life which is compatible with a protracted term of existence. The happier a human being is, the longer he lives; the more he suffers, the sooner he dies: to add to enjoyment is to lengthen life; to inflict pain is to shorten the duration of existence." It may fairly be presumed, then, that a certain amount of enjoyment in life is necessary for health, and that when the quantity actually secured is much below that point, unhealthy conditions must ensue. If, for example, poverty or embarrassed circumstances press so severely upon a cautious and conscientious man, as to leave him scarcely a moment's comfort from one year to another, he cannot fail to sink in health. If married to a female of bad temper, or who afflicts him by bad habits, and if, from these causes, he rarely enjoys a moment of happiness, so also must his health fail. In short, to be placed in any such circumstances as constitute a bar against nearly all enjoyments, must prove injurious, and tend to the shortening of life.

Enjoyments are of many kinds. Some are sensual, as the taking of agreeable food; others are intellectual, as agreeable music, reading, &c.; others are moral, as the exercise of philanthropy, the religious feelings, &c.; and some are sympathetic, and consist in the exercise of the affections and the reflection of that gratification which we have endeavoured to impart to others. We may consider as such all things over and above the plainest unrelished fare, and the supply of water, air, and a barely sufficient temperature. These are usually considered as strictly the *necessaries* of life, the others being the comforts or luxuries. The distinction is not quite correct. The first class are certainly immediately necessary to the support of life; that is to say, they are hourly, daily necessary. But more or less of what are called the comforts of life are also necessary, if we would preserve health. The only difference is, that the want of them would not tell in so short a time as the want of the so-called necessities. If a human being be shut up in a cell, and allowed only a sufficiency of unrelished and unvaried food, with air and water, the want of all the enjoyments of life, sensual, intellectual, moral, and sympathetic, will in a certain time make him utterly miserable; the health of body and mind will give way; and if the experiment be sufficiently protracted, he will perish. The ignorance which prevails on this point has led to the trial of what is called the *silent system* in prisons, which is now about to be abandoned as utterly irreconcilable with humanity. It were well if more knowledge prevailed on the subject, for, from erroneous ideas of what is necessary for healthy life, many deprive themselves or others of things which, when we take the element of time into account, are as essential to health as the supply of the air we breathe. There is, in some enthusiastic minds, a spirit of asceticism and self-mor-

tification which would give up all the enjoyments of life together. Such persons rarely fail to reduce their own health, if they do not also exercise some unhappy control to the same effect over their fellow-creatures. While self-denial for moral purposes is always admirable, and over-indulgence of every kind saps the vigour and fortitude of the human character, it should be ever kept in view that there is great danger in reducing the allowance of comforts and indulgences too low. Very rigid views of what is necessary for the support of life usually prevail, wherever the affluent have to dictate a style of living for the poor. The tendency there is to reduce allowances as nearly as possible to what may be called the *immediate necessities*; for it does not seem just or right that paupers, adults or children, should enjoy any species of gratification. But these are short-sighted views. The health of these unfortunate persons requires something more, and this something would be granted by an enlightened humanity. We have a strong manifestation of this need in the eagerness with which paupers generally desire allowances of tea or tobacco, or indeed the least variation of their diet. The craving for these luxuries is not so much, what it is generally thought solely to be, the result of bad habits long indulged in, as it is the expression of a want in the personal economy—a want which, by one means or another, must be supplied, or injurious consequences will ensue.

EXEMPTION FROM HARASSING CARES.

It is little more than a repetition of doctrines already laid down, that, for health, a human being requires an exemption from acute distress of mind and harassing cares.

Mental distress and anxiety operate through the brain upon the condition of the whole body, and, when long protracted, effectually undermine the health. "It is impossible," says Dr S. Smith, "to maintain the physical processes in a natural and vigorous condition, if the mind be in a state of suffering. Every one must have observed the altered appearance of persons who have sustained calamity. A misfortune, that struck to the heart, happened to a person a year ago: observe him some time afterwards—he is wasted, worn, the miserable shadow of himself; inquire about him at the distance of a few months—he is no more." It is Dr Smith's opinion that the nearest cause of many suicides is not strictly a desire to escape from a state of suffering, but some disease, probably inflammation of the brain, brought on by distress of mind. "By a certain amount and intensity of misery, life may be suddenly destroyed; by a smaller amount and intensity, it may be slowly worn out and exhausted. The state of the mind affects the physical condition; the continuance of life is wholly dependent on the physical condition; it follows that, in the degree in which the state of the mind is capable of affecting the physical condition, it is capable of influencing the duration of life."

Depression of mind, besides its immediate effect on the nervous system, deranges the respiration and mars the proper oxygenation and circulation of the blood. A diminished vitality is the consequence, often leading to pulmonary consumption. An excessive agitation and alarm of the selfish feelings, such as takes place in some minds on the approach of an epidemic, affects the whole system in such a way as—to use an expressive phrase of Dr Combe—"places it on the brink of disease;" and hence the notoriously great liability of persons in this state of alarm and apprehension to fall victims to the malady when it comes. It has been remarked that an army in a high state of confidence and cheerfulness after a victory, has a much smaller proportion of sick than in the opposite circumstances, or even in its ordinary condition. The usual proportion of sick in a garrison quartered, during peace, in a healthy country, is five per cent.; during a campaign, when there is more anxiety of mind, it is ten; in the event of defeat, although the circumstances be otherwise not unfavourable, the proportion rises to a much higher amount. It

is a very instructive fact, that in a large detachment of the French army cantoned in Bavaria immediately after the battle of Austerlitz, the proportion of sick was little more than *one per cent.*

GENERAL OBSERVATIONS.

The fundamental principle of all efforts to improve and preserve health has been thus stated:—"Man, as an organised being, is subject to organic laws, as much as the inanimate bodies which surround him are to laws mechanical and chemical; and we can as little escape the consequences of neglect or violation of those natural laws, which affect organic life through the air we breathe, the food we eat, and the exercise we take, as a stone projected from the hand, or a shot from the mouth of a cannon, can place itself beyond the bounds of gravitation." It may be added, that "all human science, all the arts of civilised man, consist of discoveries made by us of the laws impressed upon nature by the Author of the universe, and the applications of those laws to the conditions—which are laws also—in which man and the particular bodies and substances around him, are placed; nor, it is manifest, should any science concern us more than that which relates to the conditions on which organic life is held by each individual."

The preceding sections are but explanations, such as we have been able to afford, of the conditions under which the organic frame of man exists, and the agencies, internal and external, which operate upon it, for the maintenance of health or the introduction of disease. It must be evident, where there is a conviction of the truth of the fundamental doctrine, that individuals and societies have their health very much at their own disposal; that a careful avoidance, on the one hand, of what is noxious, and a judicious attention to what is beneficial, are what are chiefly necessary for the preservation of the human frame in health to old age; and that premature deaths, over and above those which result from unforeseen casualties, instead of being, as supposed by the untutored mind, a mysterious and irreversible decree of Providence, are simply the natural effect of our own violation of laws which Providence has appointed for our welfare. It might still be objected that human nature is such, that the due obedience and observance of those natural ordinances are not to be expected; so that the vast quantity of disease, and the great number of premature deaths, which afflict our present state of being, are equally to be regarded as things immutable, and therefore to be tranquilly submitted to. But this view would be not less a mistaken one; for there is no fact more clearly ascertained, than that disease and premature death are not, and never have been, fixed at any given amount, but yield constantly to the power of any new conditions which man may be able to introduce. Regarding clear views on this subject as of great importance, we shall here enter a little into detail.

The object is, we apprehend, to show that sickness and mortality vary both in place and in time, according to physical and organic conditions.

Inquiries into these subjects were not made in ancient times; but, during the last two hundred years, such facts have been recorded as enable us to ascertain that, in that space of time, with regard to nearly the whole of Europe, there has been a gradual improvement in health and life, in proportion to improved conditions. In Sweden, for instance, between 1756 and 1763, the annual mortality was, for males, 1 in 33½; for females, 1 in 35½; whereas, in the year 1800, it had diminished to 1 in 34½ for males, and 1 in 37½ for females. From mortuary tables preserved with considerable accuracy at Geneva, it appears that, at the time of the Reformation, one-half of the children born died within the sixth year; in the seventeenth century, not until the twelfth year; in the eighteenth century, not until the twenty-seventh year; consequently, in the space of about three centuries, the probability that a

child born in Geneva would arrive at maturity has increased fivefold. In London, in the year 1606, the annual deaths were 1 in 14½, or 7 per cent. of the population; and in plague years during that century, it reached 25 in 100, or every fourth man, woman, and child! In 1838, it was only 1 in 35½. Knowing that, at the former period, the city was dense and ill-cleaned, and that the habits of the people were not then what they are now, we cannot doubt that this diminution of mortality to less than one-half is owing to the improved conditions in which human beings now live in the metropolis. Between the years 1730 and 1750, 74 of every 100 children born in London, died before they were six years of age; but in more recent times, only 31 and a fraction out of every 100 die under the same age; that is to say, the deaths of children in London were then more than twice as numerous as they are now. About a century ago, the mortality of the children received into the London hospitals was of astonishing amount. Though the fact seems scarcely credible, we believe there is no good reason to doubt, that, of the 2800 annually received, 2690, or *twenty-three in every twenty-four*, died before they were a year old. It was at length seen that this mortality was the effect of over-crowding, impure air, and imperfect aliment; and, after an act of parliament had been procured to compel the officers to send the infants to nurse in the country, only 450 out of 2800 died in the first year. It has been ascertained that, during the last century, about a third has been added to the average expectation of life; that is to say, an individual now has as good a chance of living forty years, as he had a hundred years ago of living thirty. To what can such a fact be owing but to the diminution of the causes of disease in the improved conditions of the people.

The facts ascertained with regard to differences of mortality in different places are equally striking. A remarkable instance of the effect of marshes upon health is cited by M. Villermé. Formerly the district of Vareggio in Tuscany was in this condition, and its few miserable inhabitants were every year visited by severe agues. In 1741, floodgates were erected to keep out the sea, the marsh was dried up, and ague appeared no more. Vareggio subsequently became a populous and healthy district. The Isle of Ely is a marshy district in the east of England, and it was ascertained that, of 10,000 deaths which occurred in it between the years 1813 and 1830, no fewer than 4732 were of children under ten years of age; the proportion of deaths of children under ten in all the other agricultural districts of England being only 3505, or as about 3 to 4 of the former number. Of 10,000 deaths between ten years and extreme old age, in the same period, there were, of persons between ten and forty, 3712 in the Isle of Ely, and only 3142 in drier districts. There are some remarkable discrepancies of mortality in different counties of England. While the proportion of annual deaths in every hundred persons under six years of age is, for the whole of England and Wales, about five and a third, the proportion in Suffolk is three and a half, in Warwick six, in Middlesex eight and a third. Suffolk is an agricultural county; Warwick contains Birmingham and some other large towns; and the metropolis is situated in Middlesex: can we resist concluding that the pure air and constant exercise which children obtain in the country are the immediate means of prolonging their lives; while the narrow accommodations, impure air, and limited exercise, to be had in large towns, have exactly the contrary effect? In the general population of England, 443 in 1000 die under ten years of age; but in Manchester and Salford the number is a third larger, or 602. Here, the miserable circumstances of many of the humbler classes in Manchester—above eighteen thousand of them, for one thing, living *in cellars*—must be considered as the immediate cause of the disproportioned mortality. While the general mortality of London is, as stated, 1 annually in 35½, there are great differences with respect to different districts. In Camberwell, an open suburban district, it is

1 in 52; in Hackney, a similar district, 1 in 54; but in the huddled district of St George's, Southwark, it is 1 in 30; and in the still more dense and miserable region of Whitechapel, so much as 1 in 26, or exactly double the mortality of Camberwell. A curious investigation has been made in London, to ascertain the effect of density of population upon health. In a large district, where the population is so dense that there is only 35 square yards for each person, the annual mortality is 3428; in another district of the same population, where each individual has an allowance of 119 square yards, the mortality sinks to 2786; in a third, where there are 180 square yards to each person, the mortality is only 2289, or under two-thirds of what it is in the closest of the three districts. It was also found that, in the three districts, the mortality from typhus fever was, respectively, as we go from the roomiest to the closest, 131, 181, and 349. The proportion of sickness and mortality which the poor suffer in comparison with the rich, is thus placed in a striking point of view. Precisely similar results have been discovered in Paris. M. Villermé has there ascertained, that the deaths in some poor *arrondissements* are just double what they are in the rich. He states that, taking the whole of the French population, human life is protracted twelve and a half years among the wealthy beyond its duration among the poor; consequently, in the one class, a child, newly born, has a probability of living forty-two and a half years; in the other, only thirty years.

Taking the whole of the above facts into account, we must see that not only do health and longevity depend expressly on laws, the operation of which we can understand, but man has it in his power to modify to a great extent the circumstances in which he lives, with a view to the promotion of his organic well-being and preservation. We see that the draining of a marsh banishes the ague, that a change from city to country air diminishes mortality, and that the greater comforts possessed by the affluent secure them longer life than the poor. It may not immediately be in the power of every one to change his circumstances from the unhealthy to the healthy; but it is a great matter to know that the object is within human power, for then at least an encouragement is held out to induce each individual to make every possible effort to put himself, and to contribute to putting society, into more salubrious conditions.

The object may be said to depend partly upon individual and partly upon social efforts. Every person has some control over the quantity and quality of the food he eats, the condition of the air he breathes, and the exercise, repose, and recreation which are demanded by his muscular and nervous system, according to the principles laid down in this and similar treatises; as also some power to refrain from injurious excesses, and to avoid the various external agencies of a detrimental kind, which constantly beset him. Let him act as he ought to do in these respects, and he will reap an immediate reward in that pleasurable state of consciousness which attends a healthy condition. But some of the most important requisites for health depend on public measures. The amount of the necessities and comforts of life to be obtained by the great mass of the operative classes in all countries, depends very much upon regulations which may have been made with regard to *production and exchange*, as also those which may have been made for instructing and morally elevating and sustaining the bulk of the people. It unfortunately happens, in most countries, that, while the bearing of certain acts upon individual happiness is fully seen and provided for, those which affect the condition of communities are imperfectly understood; so that measures destructively injurious to millions will be enforced and defended by those who would severely punish the slightest wrong inflicted by one man upon another.

Measures for improving general condition with respect to air and exercise, are perhaps more readily practicable; yet here also the bearing of active principles upon great masses is so dimly seen, that, not to

speak of more positive difficulties, it is usually long before proper sanitary regulations are made. The cleaning police of most cities is certainly improved considerably within a hundred years; yet it is still far from being what it ought to be, while drainage continues to be extremely defective, and ventilation and exercise can scarcely be said to be thought of. Some facts elicited by recent parliamentary inquiry, with regard to several of our principal cities, are of a most startling kind.

Dr Arnott, when examined as to the prevalence of fever in Bethnal Green, Whitechapel, Wapping, and certain other districts in London, attributed them directly to the dirty and neglected state of these localities, instancing—"Houses, courts, and alleys without privies, without covered drains, and with only open surface gutters, so ill made that the fluid in many cases was stagnant; large open ditches containing stagnant liquid filth; houses dirty beyond description, as if never washed or swept, and extremely crowded with inhabitants; heaps of refuse and rubbish, vegetable and animal remains, at the bottom of close courts and in corners." [The amount of noxious matter which is hoarded or allowed to rest in London, is far beyond what most of its inhabitants have any conception of, as is the case with most other conditions chiefly or solely affecting the poor.] In Manchester, 18,300 persons, or one-twelfth of the whole working population, live beneath the level of the ground, with an insufficiency of both light and air. In that town, the dwellings of labourers are often built in close narrow courts, and back to back, so as to prevent ventilation; the drains are far from sufficient, and there is not in the town one free space in which the people can enjoy the slightest recreation. In Liverpool, 39,000 persons live in cellars, dark, damp, confined, ill-ventilated, and dirty. The class next above, to the number of 80,000, inhabit houses built around small courts, closely pent up, back to back, with only one entrance to each, and usually a receptacle for refuse in the centre; an arrangement which appears as if it had been expressly calculated to keep health low and mortality high. In Leeds, a similar style of building obtains, with a similar train of circumstances, "no effective drainage, inspection, or system of paving or cleansing." The greater part of this town was described in 1839 as "in a most filthy condition, demanding an immediate remedy." It was mentioned, that in a certain dirty yard, there was a house which for many years had been the seat of disease of a very malignant character: three years ago, the attention of the commissioners of police was directed to the extremely imperfect drainage of the surface-water: at that time a better escape for the refuse water was provided; and since that period, says the reporter, "I believe, we have not had a single case of fever from that particular locality." Narrow alleys and close courts, with wet filth constantly exhaling within them, and containing a close huddled population of extremely poor persons, exist in Edinburgh, where, however, an exposure to high winds makes the evil less pestilential. In Glasgow, a comparatively level city, the same peculiarity exists to perhaps a greater extent than in any other British city. This, added to the miserably insufficient succour extended by law to the poor in Scotland, renders Glasgow one of the unhealthiest cities in Europe; the mortality of the year 1837 being 1 in 24½, and the number of fever cases for the five years before 1839 at an average of 11,118 per annum. Here, also, we have a most notable instance of the counteractive power of a single sanitary principle; for a house containing about five hundred poor inhabitants, having been ventilated by a draught from each room in 1832, fever, which had previously never been absent from that dwelling, was nearly banished, only four cases occurring in the ensuing eight years, though fever raged during that period in all the districts of the city occupied by the poorer classes.

COMMERCE—MONEY—BANKS.

COMMERCE.

MAN has been defined by some naturalists as an *exchanging animal*—an animal who buys and sells, that being a thing performed by no other living creature, and therefore suitable as a distinction in character, though others, much more exalted, might readily be found. The practice of exchanging one commodity for another is doubtless coeval with the first herding of mankind together. No man, even in the rudest savage state, and who lives in the society of neighbours, can rest satisfied with such objects as he can procure or fashion by his own labour. He must depend on others for assistance, while he assists them in return. The cultivator of the ground would exchange some of its produce for an animal from the flocks of his neighbour; and both would be glad to give a portion of their wealth for the clothing or weapons made by a third party. Thus, *exchanging* becomes a matter of convenience between two parties, each of whom is anxious to obtain a share of the other's goods for a share of his own, and a mutual advantage is the result. Such desires and practices must have been displayed in the very earliest stages of society. No nation of African or Indian savages is ever found without a strong inclination to exchange the rude products of their country for the articles possessed by the traveller; an ox or sheep being perhaps eagerly offered by them for a single needle, a nail, or a small toy looking-glass.

As mankind advance in their social condition, the practice of exchanging increases; the desires and necessities become more urgent; each person finds it more profitable and agreeable to adopt and hold by one fixed employment, and to sell the produce of his labour for a variety of articles made by others, than to attempt to make every thing for himself; and, finally, for the sake of convenience, a class of persons are engaged to conduct the exchanges from one hand to another. In this improved condition, the production of articles of general consumption is called *manufacturing*; while that department of industry in which the exchanging is transacted is called *trade* or *commerce*. For still further convenience, the business of exchanging is committed to several orders of traders—the wholesale merchants, who in the first instance purchase large quantities of goods from the producers; the retail dealers, who have been supplied in smaller quantities from the merchants, and sell individual articles or minute portions to the public; and to these sometimes an intermediate dealer is added. In this manner the transfer from the workshop of the manufacturer to the house of the actual consumer is interrupted by several distinct processes of exchange, in which each seller obtains a certain profit at the expense of the person who has ultimately to buy and use the article. It is a principle of trade, that the fewer hands through which

any article is made to pass, the better for the consumer, because the article can be brought with the least burden of profits, or at the lowest price, into general use. But this principle, sound as it is in the abstract, is counteracted by another which must on no account be lost sight of. This is the principle of *convenience*. A manufacturer engaged deeply in his own pursuits finds it more profitable and agreeable to sell his articles in large than small quantities. The maker of millions of yards of cloth has no time to spend in selling single yards. If he were compelled to sell by retail, he would have no time to conduct his affairs; he could manufacture only a small quantity, and, therefore, being limited in his amount of produce and sales, he must take larger profits. Thus, upon the whole, it is much better for all concerned to allow the manufacturer to pursue his own way in selling only very large quantities to wholesale merchants. To these traders the same rule may be applied. They seek out the seats of manufacture; and, purchasing a large variety of goods, they send them to the towns and places where they are required by the public, and there the articles can be had individually from a shop. It is evident that if any man wish to buy a handkerchief, he may procure it much more cheaply from any shop in which such things are sold at an advance upon the original cost, than if he were to travel perhaps hundreds of miles to the house of the manufacturer, and there make the purchase. The use of an intermediate class to conduct exchanges is thus very conspicuous; and any attempt to revert, generally, to the original practice of causing the maker to deal with the consumer, would be entirely incompatible with an enlarged system of trade between different countries, or even between different places in the same country. We say generally, because there are instances in which makers may, with advantage to themselves and the community, sell their produce in small quantities or single articles to the public; but these are exceptions to a common rule.

Convenience, it is evident, forms a guiding principle of trade, and requires the same consideration as the actual value of an article. This, however, has been recognised only in very recent times. At one period there were laws to prevent farmers from selling their grain in a large quantity or by the lump, without exposing it in an open market. Such laws were manifestly unjust. They interfered with the liberty of the farmer, who in his capacity of manufacturer had surely a right to sell his produce in whichever way he felt it to be most for his advantage. It would be the same kind of injustice, if the law were to prevent a manufacturer of handkerchiefs from selling them at his own workshop to wholesale dealers, and causing him to take them many miles to a certain street in a certain town, and there expose them for sale in small lots to the public. It is of the greatest importance in matters of trade and com-

merce never to interfere in any shape to prevent men from dealing in whatever manner appears most beneficial and convenient to themselves, provided it be conformable with strict justice. By being left to consult their own inclinations, the public in the end, though probably in a way not easily recognisable by an unreflecting mind, reaps the advantage.

Commerce, by which we comprehend traffic carried on at home or with foreign countries, is of great antiquity, and, both in the earliest times and in our own day, has been one of the principal engines of civilisation. Among the industrious nations which at a remote period of history were planted on the borders of the Mediterranean Sea, it became a means of spreading knowledge in the interior of Asia, and many parts of Africa and Europe. Unfortunately, the intelligence which was so disseminated was afterwards obliterated by the overruling powers of barbarous and warlike nations; but the efficacy of commerce in modern times is likely to be permanent wherever its influence is extended, seeing that the greatest manufacturing and mercantile people are at the same time the most powerful and most capable of offering protection to those who sustain a commercial intercourse with them. It is exceedingly pleasing thus to reflect on what commerce is capable of effecting, independent of the actual comfort which it produces, wherever it is fairly introduced. By its appeals to the selfishness, the vanity, and other passions, good and bad, of mankind, it appears to be the best of all forerunners to the efforts of the schoolmaster and the missionary. Its influence in this respect has been remarkably exemplified in the boundless regions of Hindostan, which, by the efforts of a company of merchants, have been laid open to the settlement of enlightened men from Europe, who, though by slow degrees, will ultimately spread the blessings of education, and the decencies of social life, among many millions of human beings. In the remote islands in the Pacific Ocean, the influence of commerce has been recently of marked utility. The introduction of articles of a fanciful nature, both for the ornamenting and covering of the person, has induced a desire of following European manners and customs; and as these commodities cannot be procured but by the exchange of native commodities, a spirit of industry has consequently been produced, which cannot fail to be of both moral and physical advantage to the natives. It is always thus with the intercourse which commerce necessarily involves. New tastes are created, and to be gratified, industry must be exerted. But to witness the extraordinary influence of commerce in producing civilised and refined habits, we need not look beyond our own country. Commerce, in this its chosen seat, has caused roads every where to be cut, canals to be opened, railways to be formed, expeditious modes of travelling by sea and land to be effected; all of which great accessories to our comfort have tended in the most wonderful manner to introduce not only useful commodities and personal luxuries, but highly cultivated sentiments, literature, and the arts, into districts which at no distant period lay in a comparatively primitive condition. The intercourse which commerce in this manner requires, is the grand lever which, it is apparent, must in the first place be employed to lift the load of ignorance from off the natives of Africa; and when this lever is properly insinuated, the way will soon be prepared for the introduction of those measures of melioration which philanthropists so anxiously design.

It is obvious that this scheme of mutual interchange among nations of the commodities which they respectively produce, is agreeable to every rational principle, and must have been designed by a wise Providence for the universal benefit of his creatures. In order that manufactures may be produced, and commerce brought in to disseminate them both at home and abroad where they are wanted, no species of legislative enactment is requisite either to encourage or direct. The law which governs production and consumption is a law of nature—it is the overruling principle of *self-*

interest, by which only that quantity of manufacturer is produced which can be advantageously disposed of, and only those commodities purchased and consumed which the wants of individuals require. And, curiously enough, this principle of self-interest, if allowed free scope, is uniformly and sufficiently competent to regulate both the production and consumption of commodities, to a degree more nice and satisfactory than could be attained by the best-devised statutes which the wisest legislators could enact. The grand principle, therefore, which can alone regulate commerce and manufactures, is found in the natural passion for gain; and the sole essential requisite for the successful advancement of mercantile and manufacturing industry and wealth among the people, is for the people to be let alone.

Evident as these principles must be to all who have any knowledge of social life, they have, either from ignorance or some other cause, been generally lost sight of by governments in all ages of the world, and plans have been contrived to regulate that which, if left alone, would have much better regulated itself. To such an extent have regulating and restrictive laws been carried in some countries, that they have nearly annihilated both manufactures and legitimate commerce, and reduced masses of the people to the condition of paupers, besides encouraging the pernicious and demoralising pursuits of the smuggler. The restrictions and regulations which governments usually impose upon commerce, do not perhaps originate so much in the plea that manufacturers and merchants stand in the condition of children, and require to be taken care of lest they should hurt themselves, as from the unfortunate exigencies under which the governments happen to be placed. They have all less or more engaged in wars, which have been conducted at an enormous expense to their respective countries. In order to liquidate these expenses, all kinds of taxes are levied, directly and indirectly; but as the levying of these taxes breeds discontent, large bodies of military have usually to be kept up, to act as an armed national police. Thus, the people of these countries have for ages to go on paying not only the price of the wars, or the interest of the sums borrowed and laid out upon the wars, but as much more for the military force afterwards imposed upon them. What is more distressing, the people have probably to give a deal of money, in order that their respective governments may be the more able to secure the attachment of men of consequence to assist in allaying the general clamours for a redress of grievances. This is a very rough view of the matter, but it is enough to show the dreadful exigencies into which nations fall, by their engaging in wars or other expensive follies. In whatever manner, however, national exigencies originate, the plan pursued for relief consists chiefly in the imposition of duties on certain commodities much in demand, and at various stages of their manufacture, transmission, and sale. It is likewise customary to impose duties on goods imported from foreign countries, with the view of protecting the manufacturers of such articles in this country; but this only benefits a class, or a few persons, at the expense of the whole community, and, therefore, all such duties are in the main as detrimental to trade and the public welfare as those imposed for the liquidation of national debt and expenditure.* "There is (observes Mr McCulloch) no jugglery in commerce. Whether it be carried on between individuals of the same country, or of different countries, it is in all cases bottomed on a fair principle of reciprocity. Those who will not buy need not expect to sell, and conversely. It is impossible to export without making a corresponding importation. We get nothing from the foreigner gratuitously; and hence, when we prevent the importation of produce from abroad, we prevent, by the very same act, the exportation of an equal amount of British produce. All that the exclusion of foreign commodities ever effects, is the substitution of one sort of demand for another. It has

* See article POLITICAL ECONOMY.

been said, that 'when we drink beer and porter we consume the produce of English industry, whereas, when we drink port or claret we consume the produce of the industry of the Portuguese and French, to the obvious advantage of the latter, and the prejudice of our countrymen?' But how paradoxical soever the assertion may at first sight appear, there is not at bottom any real distinction between the two cases. What is it that induces foreigners to supply us with port and claret? The answer is obvious:—We either send directly to Portugal and France *an equivalent in British produce*, or we send such equivalent, in the first place, to South America for bullion, and then send that bullion to the Continent to pay for the wine. And hence it is as clear as the sun at noonday, that the Englishman who drinks only French wine, who eats only bread made of Polish wheat, and who wears only Saxon cloth, gives, by occasioning the exportation of a corresponding amount of British cotton, hardware, leather, or other produce, the same encouragement to the industry of his countrymen, that he would were he to consume nothing not immediately produced at home. A quantity of port-wine and a quantity of Birmingham goods are respectively of the same value; so that, whether we directly consume the hardware, or having exchanged it for the wine, consume the latter, in so far as the employment of British labour is concerned, it is altogether indifferent.*

From these explanations, it will be observed that it is immaterial what is given in exchange for imported goods—whether money or native produce. At the same time, it must be understood that if money is given, there must exist some active industry in the country by which the money is realised. As a general question in commerce, it is of no consequence what is the nature of the industry by which the money is produced. It may consist in the raising of superabundant crops, or other raw produce for exportation, or of manufacturing raw and comparatively valueless materials into articles of value and demand, or of carrying goods from one country to another. Unless a country possess one or more of these branches of industry, it is without the means of paying for imported articles, and must retire from the field of general commerce. England is not of sufficiently large dimensions to export superabundant crops of grain, but it possesses in an extraordinary degree the means of manufacturing mineral and other substances into articles for exchange, and it derives no inconsiderable profit from the carrying of commodities. Its manufactured goods, therefore, pay for imports of foreign articles, including bullion or the raw material of money, and these again, in a manufactured state, are a fund for the payment of still further imports. Thus the wealth of our country has increased.

PRINCIPLES OF COMMERCE.

The practice of commerce is in a great measure dependent on mutual good faith, and the integrity of seller and buyer, and can in no case permanently flourish where these fundamental qualities are wanting. The first or great leading quality, therefore, in the character of a merchant, ought to be scrupulous honesty both in word and deed. The article which he proposes to dispose of must be exactly what he declares it to be, not inferior or in any respect unsound in its nature. If it possess any blemishes, these must be announced to the buyer before the bargain is concluded, and, if necessary, though at a considerable loss, an allowance made for them. The merchant is not less called on to be faithful in the fulfilment of all promises which he may make, whether with respect to goods or their payment; because those to whom the promises have been made may on that account have made similar promises to others, and, therefore, the breaking of a single promise may prove injurious in every link of a whole train of transactions. Perfect honesty or integrity is a fundamental principle of trade; and the next most import-

ant are, strict regularity in all proceedings, according to established usage, and also steady perseverance. The merchant must give regular attendance during the hours of business, be regular in executing all orders and answering all letters; regular in the keeping of his books, and in the reckoning of his stock and moneys; in short, he must be methodic and careful in all branches of his concerns, for without this species of attention, the best business is apt to become confused, and to be ultimately ruined. What is true of individuals is true when applied to a whole nation. No people have ever attained opulence and high mercantile consideration, who have not possessed a character for integrity and regularity in all their dealings.

Besides these indispensable qualities in the individual character of a merchant or tradesman, there is required a happy combination of enterprise and prudence with the utmost coolness—enterprise to embrace favourable opportunities of buying and selling, and prudence and coolness to restrain from engaging in over-hazardous and ruinous speculations. In all his transactions, the man of business is understood to proceed upon a cool inflexible principle of doing that which is most advantageous for himself, without fear or favour; because in commerce each party is supposed to be governed by motives of self-interest (always within the rules of honesty and propriety), and is under no obligation to deal from mere personal regard, or any kind of friendly consideration. In commerce there is, strictly speaking, no friendship. If there be friendship among the parties concerned, it is a thing aloof from business transactions—a matter of private arrangement—and is only to be regarded as such. On this account, even among the most intimate friends, there must be an exact mode of dealing, and the most accurate counting and reckoning.

The British, for several centuries, seem to have been endowed, above all other nations, with those qualities of mind which are suitable for the conducting of commerce on an enlarged and liberal scale. Their integrity, persevering industry, enterprise, prudence, and liberality of sentiment, have never been excelled. In patient industry they have been rivalled by the Dutch; but in point of enterprise and liberality, that people have fallen far short of them, and their trade has languished accordingly. The British are pre-eminently a commercial as well as a manufacturing people. Taking them generally, they possess a spirit of restless industry, which renders them actually unhappy unless when busily engaged in some pursuit calculated to enrich them, or at least to produce for their families the means of a respectable subsistence. The Americans, who are but a branch of the same British stock, are equally, if not more, remarkable for this fervent spirit of industry; and, though only set up as a separate nation within a period of sixty years, and less distinguished for their integrity and prudence than the English, have already distanced many of those dignified European principalities and powers which first discovered and colonised their country. The French, the Germans, the Spaniards, the Portuguese, the Italians, and others, though each possessing a larger or smaller extent of manufactures and commerce, are obviously deficient, in a national sense, of the eager spirit of industry which is so characteristic of the people of Great Britain. Taken in the gross, they are too apt to addict themselves to amusement in preference to business. They delight in holidays, and will at any time leave their work to mingle in a dance or some kind of buffoonery, in which an Englishman would be ashamed to appear. Scarcely one of the continental nations, moreover, has yet settled down under a well-conducted government appointed by the people. There indeed seems to be little which is settled amongst them. Some of the principal are yet at that stage of social life which was common in England about the reign of Henry VII.; others are not farther advanced than a period considerably earlier; and all have yet a great deal to suffer and to learn before they attain that state of quietude and security to

* Dictionary of Commerce,

life and property, that condition of domestic comfort and national prosperity, which Great Britain, with all its faults, so amply enjoys.

COMMERCIAL TERMS AND TRANSACTIONS.

The following explanations of the principal terms used in commerce will illustrate the mode of conducting business transactions.

Firm.—Every business, whether private or public, is conducted under a specified designation or title, called the name of the firm. This name may be that of a single individual to whom the business belongs, or of two or more individuals, or any title which it may be found advisable to adopt. Sometimes the name of a firm remains long after all who are indicated by it are dead. In such a case, the business has passed into the hands of new proprietors, who, though legally responsible for its obligations, are not for some private reason inclined to change the old and well-known title of their firm. A particular firm or business-concern is sometimes personified in the term *house*—as, Such a house does a great deal of business, &c.

Company.—Two or more individuals engaged in one business constitute a company or copartnership, each individual being called a partner. Companies are of two kinds, private and public. A private company is organised by a private arrangement among the parties, each having certain duties to perform and a certain share in the concern. In companies of the private and common description, no individual can leave the concern at his own pleasure, for by doing so he might seriously injure or embarrass his partners. He can withdraw only after giving a reasonable warning, by which time is allowed to wind up the concern, or place it in a condition to pay him back the capital which he has risked, or the profits which are his due. No partner, however, can transfer his share to another person, by which a new member would be introduced into the firm, without the consent of the partners.

The profits of partnerships are divided according to a specified agreement or deed of copartnership. Generally, in the case of partnerships of two or three persons, each receives the same share on the occasion of an annual division, but in other cases, a partner may not be entitled to more than a fourth or sixth part of what another receives. The amount of capital which a partner invests in the concern, the service he can be to the business, and other circumstances, regulate the amount of his share. When each of two persons sinks the same capital, but one takes the whole of the trouble, then he on whom the trouble falls, who is called the active partner, is entitled to receive a stated sum in the form of salary over and above his share of profits. Whatever be the share which individual partners have in a concern, the whole are equally liable for the debts incurred by the company, because the public give credit only on the faith that the company generally is responsible. He who draws the smallest fraction of profit, failing the others, may be compelled to pay the whole debts. On this account, every partner on leaving a company should be careful to advertise in the *Gazette* and newspapers that he no longer belongs to the firm of which he was a member; he is then responsible for no debts incurred subsequent to the announcement.

Public companies are very different; they consist of a large body of partners, or proprietors of shares, the aggregate amount of which forms a joint stock, and hence such associations are called *joint-stock companies*. They are public, from being constituted of all persons who choose to purchase shares, and these shares or rights of partnership are also publicly saleable at any time without the consent of the company. The value of a share in a joint-stock company is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the stock of the company. Unless specially provided for in the fundamental deed of copartnership, every member of a joint-stock company is liable in his whole personal property or fortune

for the debts of the concern. In some instances this liability is obviated by the provisions of an act of parliament, or parliamentary charter, establishing the company. Joint-stock companies are managed by directors appointed by the shareholders.

It is an axiom in commerce, that business is much better conducted by single individuals for their own behoof, than by companies of any kind; as respects joint-stock associations, they are only useful in very great concerns, requiring enormous capital, and involving serious risks of loss.

Capital.—What is now termed capital was in former times called *stock*. The capital of a merchant is strictly the amount of money which he embarks in his trade, or trades upon, that is, employs for buying goods, paying wages of servants, and liquidating all debts when due. When trading within the limits of his capital, business is done upon a secure footing; but if he proceed beyond these, in any material degree, he is said to be *over-trading*, and is exposed to the chance of ruin or very serious embarrassment. Trading beyond the amount of available capital, is, nevertheless, a prevailing error, and causes innumerable bankruptcies. With a comparatively small capital, a tradesman may carry on a large business, by receiving payments shortly after making his outlays. By this means, there is a rapid turning over of money, and small profits upon the various transactions speedily mount up to a large revenue. For example, if a tradesman turn over his capital twelve times in the year, at each time receiving money for what he sells, he can afford to do business on a twelve times less profit than if he could turn over the same capital only once in a year. This leads us to a consideration of credit.

Credit.—Credit in business is of the nature of a loan, and is founded on a confidence in the integrity of the person credited, or the borrower. An individual wishes to buy an article from a tradesman, but he has not money to pay for it, and requires to have it on credit, giving either a special or implied promise to pay its value at a future time. This is getting credit; and it is clear that the seller is a lender to the buyer. In all such cases, the seller must be remunerated for making his loan. He cannot afford to sell on credit on the same favourable terms as for ready money; because, if he were to receive the money when he sold the article, he could lay it out to some advantage, or turn it over with other portions of his capital. By taking credit, the buyer deprives the seller of the opportunity of making this profit, and accordingly he must pay a higher price for the article, the price being increased in proportion to the length of credit. It very ordinarily happens that the seller himself has purchased the article on credit; but this only serves to increase its price to the consumer, and does not prevent the last seller from charging for the credit which he gives and the risk of ultimate payment which he runs. Credit for a short period is almost essential in all great transactions; but when going beyond fair and reasonable limits, it acts most perniciously on trade, by inducing heedless speculation, and causing an undue increase in the number of dealers with little or no capital. An excessive competition among these penniless adventurers is the consequence; each strives to undersell the other, with the hope of getting money to meet his obligations, and thus vast quantities of goods are sometimes thrown upon the market below the original cost, greatly to the injury of the manufacturer and the regular trader. What are called “gluts in the market” frequently ensue from causes of this nature.

Defoe, who wrote upwards of a century ago, makes the following observations on credit and over-trading, in his *Complete English Tradesman*:—“There are two things which may properly be called over-trading, and by both of which tradesmen are often overthrown: 1. Trading beyond their stock [or capital]; 2. Giving too large credit. A tradesman ought to consider and measure well the extent of his own strength: his stock of money and credit is properly his beginning; for credit is a stock as well as money. He that takes too

much credit is really in as much danger as he that gives too much credit; and the danger lies particularly in this, if the tradesman over-buys himself, that is, buys faster than he can sell, buying upon credit, the payments perhaps become due too soon for him; the goods not being sold, he must answer the bills upon the strength of his proper stock—that is, pay for them out of his own cash; if that should not hold out, he is obliged to put off his bills after they are due, or suffer the impertinence of being dunned by the creditor, and perhaps by servants and apprentices, and that with the usual indecencies of such kind of people. This impairs his credit, and if he comes to deal with the same merchant or clothier, or other tradesman again, he is treated like one that is but an indifferent paymaster; and though they may give him credit as before, yet depending that if he bargains for six months, he will take eight or nine in the payment, they consider it in the price, and use him accordingly; and this impairs his gain, so that loss of credit is indeed loss of money, and this weakens him both ways.

A tradesman, therefore, especially at his beginning, ought to be very wary of taking too much credit; he had much better slip the occasion of buying now and then a bargain to his advantage, for that is usually the temptation, than buying a greater quantity of goods than he can pay for, run into debt, and be insulted, and at last ruined. Merchants, and wholesale dealers, to put off their goods, are very apt to prompt young shopkeepers and young tradesmen to buy great quantities of goods, and take large credit at first; but it is a snare that many a young beginner has fallen into, and been ruined in the very bud; for if the young beginner does not find a vent for the quantity, he is undone; for at the time of payment the merchant expects his money, whether the goods are sold or not; and if he cannot pay, he is gone at once. The tradesman that buys warily, always pays surely, and every young beginner ought to buy cautiously; if he has money to pay, he need never fear goods to be had; the merchants' warehouses are always open, and he may supply himself upon all occasions, as he wants, and as his customers call." It certainly "is not possible in a country where there is such an infinite extent of trade as we see managed in this kingdom, that either on one hand or another it can be carried on without a reciprocal credit both taken and given; but it is so nice an affair, that I am of opinion as many tradesmen break with giving too much credit as break with taking it. The danger, indeed, is mutual, and very great. Whatever, then, the young tradesman omits, let him guard against both giving and taking too much credit."

Orders.—An order is a request from one dealer to another to supply certain goods. An order, when in writing, should be plain, explicit, and contain no more words than are necessary to convey the sense in a simple, courteous manner. The same rule applies to all letters of business, which, by the practice of trade, are confined to their legitimate object. He that affects a rambling and bombastic style, and fills his letters with long harangues, compliments, and flourishes, should turn poet instead of tradesman, and set up for a wit, not a shopkeeper. A tradesman's letters should be plain, concise, and to the purpose; no quaint expressions, no book-phrases; and yet they must be full and sufficient to express what he means, so as not to be doubtful, much less unintelligible. We can by no means approve of studied abbreviations, or leaving out needful conjunctive terms and pronouns in trading letters; as, for example, "Have just received yours of the 11th," &c.; which ought to be expressed as follows—"I have just received your communication of the 11th instant," &c. The leaving out of pronouns and other words in a business letter, gives it a mean appearance.

Counting-house; in French *bureau*; in Dutch *kantoor*.—The counting-house is the office in which a merchant's literary correspondence, book-keeping, and other business is conducted. The English merchant's counting-house is a model of neatness and regularity. Its fur-

niture consists chiefly of desks for the clerks, and the books of the establishment, which are secured at night in an iron or fire-proof safe. Almost every different business requires a different set of books, but the mode of keeping them is generally the same. The usual set of books comprises a day-book, in which sales or purchases on credit are individually entered as they occur; a ledger, into which all these entries are engrossed in separate accounts; a journal or note-book, for entering miscellaneous transactions; a cash-book, in which every payment or receipt of money is regularly entered; a letter-book, into which all letters are copied before they are sent off; and a bill-book, for the entering of bills payable and receivable. In large concerns there are various other books, as foreign-ledger, town-ledger, country-ledger, &c. The art of book-keeping is simple. It requires only a competent knowledge of arithmetic, and skill in penmanship, with a little training in the method of entering and posting accounts. The strictest care and accuracy are desirable. It is an understood rule, that no book should show a blot or erasure; a leaf, also, should never on any account be torn out, whatever blotch or error it contains. The reason for this scrupulous care is, that a merchant's books should be a clear and faithful mirror of his transactions, and an evidence of his integrity. In the case of misfortune in trade, or other circumstance, the books may be subjected to a rigid judicial examination, and the appearance of an erasure or torn-out leaf may lead to conjectures of an unpleasant nature and consequences. When an important error occurs in book-keeping, it is better to let it remain and write *error* below it, than to make a large erasure or to cut out the leaf.

From the books kept by a merchant, a condensed view of his affairs ought to be annually made up. This document contains an *inventory* or list of goods, money debts owing to the merchant, or other available property; also a contra list of all debts and other obligations due by the merchant. Both being balanced, the residue, whether for or against the merchant, is at once observable. Every man in trade, for at least his own satisfaction and government, should make up a *balance-sheet* of this nature annually.

Bill of Parcels.—An account or list of items of goods, given to their purchaser by the seller, or delivered along with the goods at the purchaser's house. Should a purchaser dispute the delivery of the goods, it is necessary to produce proof of the fact; when delivered to carriers, a receipt is usually given by subscribing a parcel-book.

Invoice.—A bill or account of goods, which is forwarded separately, announcing the date of their dispatch and the particular conveyance by which they are sent. If the seller fail to forward an invoice by post, and the goods be lost at sea while on their way, the purchaser is not answerable, for he is not supposed to know how or when the goods were sent, and therefore could not insure against their loss. The careful sending of invoices forms an important duty of a merchant's clerk.

Carriers.—Persons who undertake to convey goods from one place to another, whether by land or water, are carriers; and the carrying trade, as it is called, forms now a large and varied department of human industry. "Carriers are bound to receive and carry the goods of all persons, for a reasonable hire or reward; to take proper care of them in their passage; to deliver them safely, and in the same condition as they were received (excepting only such losses as may arise from the act of God or the king's enemies); or in default thereof, to make compensation to the owner for whatever loss or damage the goods may have received while in their custody, that might have been prevented. Hence a carrier is liable, though he be robbed of the goods, or they be taken from him by irresistible force. On the same principle, a carrier has been held accountable for goods accidentally consumed by fire while in his warehouse."* Violent storms, tempests, and light-

* M'Culloch.

ning, are considered to be "the act of God," or such as no human precaution could have averted, and no fraudulent intention could have produced.

Bill of Lading.—A formal acknowledgment or receipt given by sailing masters for goods put on board their vessels, including a promise to deliver them safely as marked and addressed to their designed destination, always, however, excepting loss or injury by the act of God, the king's enemies, fire, or the dangers or accidents of the sea. This bill of lading is usually a printed form, filled up with writing, and concludes with the quaint and pious wish—"And so God send the good ship to her destined port in safety: Amen." A set of two bills of lading is furnished to the shipper of the goods, one of which he retains for his own satisfaction, and the other is forwarded by post, like an invoice, to the person to whom the goods are sent. When the ship arrives at its destined port, this document can be employed to cause the captain of the vessel to deliver the goods therein mentioned.

Debenture.—This is the name of a formal certificate employed to recover a certain amount of drawback of duties from the customhouse on goods exported. The exporter draws up and signs the certificate, the signature being attested by a magistrate; and being forwarded to the customhouse, it is compared with the return of the officer who has seen the goods packed and sealed. After a certain period has elapsed, the duties are paid to the exporter. The meaning of this transaction is, that on exporting goods, any king's duty that may have been imposed upon them is paid back to the exporter, so as to relieve the foreign or colonial receiver from the burden of using taxed commodities. It also acts as a bounty on exportation.

Customs—Excise.—The duties or taxes imposed upon goods entering or going out of the country are called *customs*, and those imposed upon goods at the period of their manufacture in the country, are called *excise duties*. Both form a prime element in the national revenue, and are levied by boards of customs and excise, each having an extensive ramification of subordinate functionaries, for the imposition and collection of the duties. A customhouse is established at every principal port. Nearly all customs and excise duties must be paid at the time the goods are passed through the hands of the officers of either department, and fall in the first instance on the merchant and manufacturer. They, however, enhance the price of the commodities, and are therefore ultimately paid by the consumer. For the accommodation of merchants, the customhouses in the different chief ports possess large warehouses or depôts for goods, called *bonded warehouses*. Goods subject to duty, may, on importation, be consigned to these depôts, where they are allowed to remain till the merchant finds it convenient to remove them and pay the accustomed duties. Until removed, therefore, the commodities in bond can hardly be said to be imported into the country, being in the condition of goods still lying in a foreign port.

Lloyd's.—Lloyd is not the designation of any individual or of any company; it is a name used in reference to a set of subscription rooms, or coffee-house, in London. Formerly, the place of resort was in the Royal Exchange, but since the destruction of that building by fire, the place of meeting is in the neighbourhood of that locality. One of the rooms at Lloyd's is devoted to subscribers who follow the profession of marine insurers, technically called *underwriters*, from their writing under, or subscribing to, certain obligations in deeds presented for their acceptance. When a person wishes to insure a ship, or goods in a ship, against damage or loss at sea, he offers the risk to these underwriters, and they are at liberty to accept it for a specified premium. The policy or deed expressive of the insurance is usually signed by more than one underwriter, so as to divide the risk. Lloyd's is not only a centre point in the metropolis for all sea insurance business, but is the place to which every species of intelligence respecting shipping is forwarded from all

parts of the world; and this information is exhibited publicly in one of the rooms, for the inspection of all. The intelligence is for the most part sent by appointed agents, one part of whose duty consists in investigating the cause of damage to vessels, and taking charge of wrecked property for behoof of the underwriters, whoever they may be. The lists made up and exhibited at Lloyd's, furnish authentic information for the use of merchants and shippers of goods all over the united kingdom.

Vendue.—This is a colonial phrase, used instead of *public auction*. To sell goods at vendue is to dispose of them at auction. The place of sale is sometimes called "the Vendue."

Dutch Auction.—In common auction, the highest bidder by competition is the purchaser; but according to the process of sale called Dutch auction, there is a different mode of determining the successful bidder. According to this plan, the article is put up at a certain nominal price, which is gradually lowered, and the first who speaks and offers the sum mentioned by the auctioneer is at once knocked down as the purchaser. This is the fairest mode of auctioneering; it prevents competition, and the article brings its exact value—that which it is worth in the estimation of those present.

Official and declared Value.—All goods exported are entered in the customhouse books as of so much *official value*. This value is quite illusive as respects the real value of the articles. The official valuation is according to an estimate of the price 1694, without reference to the alteration of prices since that period. Knowing the fixed official price, we may be able to estimate the exact quantities, but this is a matter which few private individuals understand. The *declared value* is the price announced by the exporters of the goods, and amounts to nothing more than a rough estimate; it being necessary only to declare the value at something near the reality, for purposes of taxation, or making up reports of the export trade.

Insolvency, Bankruptcy.—When a person is not in circumstances to pay his debts in full, he is *insolvent*, which is nearly equivalent to being bankrupt: the term bankrupt, however, is more commonly applied to one who is legally announced or gazetted as being insolvent. The term bankrupt is derived from *bancus* a bench, and *ruptus* broken, in allusion to the benches formerly used by the money-dealers in Italy, which were broken in case of their failure to pay their debts. The law prescribes a certain form of procedure in the case of commercial insolvency, which has the effect of deliberately investigating the cause of the misfortune, and relieving the bankrupt from all obligations, on yielding up his entire property. Only persons in trade are entitled to the benefit of this bankrupt law, all others being excluded; so that, in the event of their insolvency, they must submit to the common laws respecting debtors, which are in some respects very rigorous. A bankrupt who has received a discharge or certificate from a competent authority, being released from all pecuniary claims, may again enter business for his own behoof without any fear of molestation; but a debtor who has merely taken the benefit of the Insolvent Act in England, or process of *Cessio Bonorum* in Scotland, though immediately relieved from prison and left at liberty to pursue any line of industry, the property he may accumulate is at all times liable to seizure by his former creditors.

A commission of bankruptcy in Scotland is entitled a *sequestration*, meaning that the property of the bankrupt is officially sequestered, or taken possession of, for behoof of creditors.

BRITISH COMMERCE.

British commerce is in two distinct branches—*inland*, or that which takes place within the country, and *export and import*, or that which pertains to foreign transactions. The inland trade conducted for home consumption is at least ten times the amount of the foreign trade. It is calculated that commodities are produced within

the country annually to the value of *five hundred millions of pounds*, fully nine-tenths of which are sold from hand to hand, or accumulate as capital, while the remainder, or nearly one-tenth, is exported. All this is exclusive of the sale of imported foreign productions.

Comparatively small as is the foreign trade of the united kingdom, it employs a larger commercial marine than that of any other nation. In 1836, the united kingdom and its possessions in Europe owned 20,388 ships, with a burden of 2,349,749 tons; the colonies at the same time owned 5432 ships, with 442,897 tons; total 25,820 ships, with 2,792,646 tons. All this is exclusive of ships of foreign proprietorship carrying on trade with the united kingdom.

Within a recent period, the manufactures and commerce of Scotland have wonderfully increased. The iron manufactures of Carron, and the cotton and silk manufactures of Glasgow and Paisley, are known all over the world. The sailcloth and coarse linen manufactures of Dundee, now one of the most flourishing ports in the empire, have greatly tended to the advancement of the Scottish export trade. The annual value of the Scotch manufactures was recently calculated to exceed £14,000,000. The tonnage of vessels on the Clyde is nearly as great as that of all Ireland, the tonnage of which, in 1828, only amounted to 97,379 tons—not one-third of the total tonnage of Scotland; the tonnage of Aberdeen is as great as that of Dublin and Belfast, the two principal Irish ports, put together. The Irish trade, however, is increasing, chiefly by means of steam navigation.

The most important commercial cities of England, besides London, are Liverpool, Bristol, and Hull; the most important manufacturing towns are Manchester, Birmingham, Leeds, Nottingham, Halifax, Rochdale, &c. In Scotland, the principal commercial places are Glasgow, Greenock, Leith, Dundee, and Aberdeen. The foreign trade of Glasgow and Greenock extends to the West Indies, the United States, the British American colonies, Brazil, and the whole continent of Europe. The foreign trade of Leith, Dundee, and Aberdeen, extends to the West Indies, America, the Mediterranean, and the Baltic. The greatest commercial cities of Ireland are Dublin, Cork, Wexford, Waterford, and Belfast. Nearly two-thirds of the traffic of Great Britain is carried on in London, and about one-sixth of the whole shipping of the empire belongs to that port. London is likewise the centre point for the negotiation of all the great commercial and pecuniary transactions in the united kingdom.

Both the export and import trade of the united kingdom have been steadily increasing for a number of years, in proportion as restrictions have become less harassing, as duties have been remitted, and as population has advanced. Not counting odd thousands, the following presents a view of this increase:—In 1800, the official value of the exports from Great Britain, of British manufactures and Irish produce, was twenty-two millions; in 1810, thirty millions; in 1821, thirty-seven millions; in 1828, fifty-one millions; and in 1830, fifty-five millions. This is not estimating the export of foreign and colonial produce, or exports from Ireland. The value of imports into Great Britain rose in a similar manner, from twenty-four millions in 1800, to forty-two millions in 1830.

Since this period, the foreign trade of the country has undergone some changes. A return to parliament published in March 1840, shows the state of our foreign and domestic interests in the years 1838 and 1839. In the former year, the declared value of British and Irish produce and manufactures exported amounted to £43,344,631, and in 1839 to £45,281,254. There has been an increase in the exportation of cotton, linen, woollen, and silk goods, and woollen yarn; also in hardwares and cutlery, iron and steel, and other metals, and earthenware; and a falling off in coal, salt, cotton yarn, linen yarn, wool, and refined sugars. The following is an abstract of the annual accounts, showing the official value of goods exported in 1838 and 1839.

	1838.	1839.
Coals and culm, - - - - -	£485,950	£543,156
Cotton manufactures, - - - - -	16,715,857	17,694,303
Cotton yarn, - - - - -	7,431,869	6,857,826
Earthenware, - - - - -	651,344	768,496
Glass, - - - - -	377,283	371,270
Hardwares, and cutlery, - - - - -	1,498,327	1,819,000
Linen manufactures, - - - - -	2,730,270	3,422,488
Linen yarn, - - - - -	836,163	814,607
Metals, viz. iron and steel, - - - - -	2,635,692	2,702,738
copper and brass, - - - - -	1,221,732	1,298,977
lead, - - - - -	154,126	195,640
tin, in bars, &c., - - - - -	101,846	112,620
tin plates, - - - - -	436,577	345,442
Salt, - - - - -	223,456	219,069
Silk manufactures, - - - - -	777,280	865,768
Sugar, refined, - - - - -	553,247	213,738
Wool, sheep or lambs', - - - - -	434,006	361,829
Woollen yarn, - - - - -	384,535	401,188
Woollen manufactures, - - - - -	5,795,069	6,278,099
Total,	£43,344,631	£45,281,254

The gross amount of customs' duties inwards in 1838 was £22,966,214, and in 1839, £23,278,089. The gross amount of excise duties for the year ending October 1838 was £11,827,788, and for the year ending October 1839, it was £12,152,171; thus the customs and excise duties produce annually upwards of *thirty-four millions of pounds* to the national revenue.

MONEY.

Origin and Nature of Money.—In a rude state of society, exchanges are made by bartering one article for another, according to some kind of understood value. "But when the division of labour first began to take place (says Smith), this power of exchanging must frequently have been very much clogged and embarrassed in its operations. One man, we shall suppose, has more of a certain commodity than he himself has occasion for, while another has less. The former, consequently, would be glad to dispose of, and the latter to purchase, a part of this superfluity. But, if this latter should chance to have nothing that the former stands in need of, no exchange can be made between them. The butcher has more meat in his shop than he himself can consume, and the brewer and the baker would each of them be willing to purchase a part of it; but they have nothing to offer in exchange, except the different productions of their respective trades, and the butcher is already provided with all the bread and beer which he has immediate occasion for. No exchange can, in this case, be made between them. He cannot be their merchant, nor they his customers; and they are all of them thus mutually less serviceable to one another. In order to avoid the inconvenience of such situations, every prudent man, in every period of society, after the first establishment of the division of labour, must naturally have endeavoured to manage his affairs in such a manner as to have at all times by him, besides the peculiar produce of his own industry, a certain quantity of some one commodity or other, such as he imagined few people would be likely to refuse in exchange for the produce of their industry.

Many different commodities, it is probable, were successively both thought of and employed for this purpose. In the rude ages of society, cattle are said to have been the common instrument of commerce; and though they must have been a most inconvenient one, yet in old times we find things were frequently valued according to the number of cattle which had been given in exchange for them. The armour of Diomedes, says Homer, cost only nine oxen; but that of Glaucus cost a hundred oxen. Salt is said to be the common instrument of commerce and exchanges in Abyssinia; a species of shells in some parts of the coast of India;

dried cod at Newfoundland; tobacco in Virginia; sugar in some of our West India colonies; hides or dressed leather in some other countries; and there is at this day a village in Scotland where it is not uncommon, I am told, for a workman to carry nails, instead of money, to the baker's shop or the ale-house.

In all countries, however, men seem at last to have been determined by irresistible reasons to give the preference, for this employment, to metals above every other commodity. Metals can not only be kept with as little loss as any other commodity, scarce any thing being less perishable than they are, but they can likewise, without any loss, be divided into any number of parts, as by fusion those parts can easily be re-united again; a quality which no other equally durable commodities possess, and which, more than any other quality, renders them fit to be the instruments of commerce and circulation. The man who wanted to buy salt, for example, and had nothing but cattle to give in exchange for it, must have been obliged to buy salt to the value of a whole ox or a whole sheep at a time. He could seldom buy less than this, because what he was to give for it could seldom be divided without loss; and if he had a mind to buy more, he must, for the same reasons, have been obliged to buy double or triple the quantity, the value, to wit, of two or three oxen, or of two or three sheep. If, on the contrary, instead of sheep or oxen, he had metals to give in exchange for it, he could easily proportion the quantity of the metal to the precise quantity of the commodity which he had immediate occasion for.

Different metals have been made use of by different nations for this purpose. Iron was the common instrument of commerce among the ancient Spartans; copper among the ancient Romans; and gold and silver among all rich and commercial nations.

Those metals seem originally to have been made use of for this purpose in rude bars, without any stamp or coinage. Thus we are told by Pliny, upon the authority of Timæus, an ancient historian, that, till the time of Servius Tullius, the Romans had no coined money, but made use of unstamped bars of copper to purchase whatever they had occasion for. These rude bars, therefore, performed at this time the function of money.

The use of metals in this rude state was attended with two very considerable inconveniences; first, with the trouble of weighing, and secondly, with that of assaying them. In the precious metals, where a small difference in the quantity makes a great difference in the value, even the business of weighing, with proper exactness, requires at least very accurate weights and scales. The weighing of gold, in particular, is an operation of some nicety. In the coarser metals, indeed, where a small error would be of little consequence, less accuracy would, no doubt, be necessary. Yet we should find it excessively troublesome, if every time a poor man had occasion either to buy or sell a farthing's worth of goods, he was obliged to weigh the farthing. The operation of assaying is still more difficult, still more tedious, and, unless a part of the metal is fairly melted in the crucible, with proper dissolvents, any conclusion that can be drawn from it is extremely uncertain. Before the institution of coined money, however, unless they went through this tedious and difficult operation, people must always have been liable to the grossest frauds and impositions; and, instead of a pound weight of pure silver, or pure copper, might receive in exchange for their goods an adulterated composition of the coarsest and cheapest materials, which had, however, in their outward appearance, been made to resemble those metals. To prevent such abuses, to facilitate exchanges, and thereby to encourage all sorts of industry and commerce, it has been found necessary, in all countries that have made any considerable advances toward improvement, to affix a public stamp upon certain quantities of such particular metals as were in those countries commonly made use of to purchase goods. Hence the origin of *coined money*, and of those public offices called mints; institutions exactly of the same nature with those of

the aulnagers and stampmasters of woollen and linen cloth. All of them are equally meant to ascertain, by means of a public stamp, the quantity and uniform goodness of those different commodities when brought to market.*

It will be understood from these explanations that money is only an article which can be conveniently used in exchanging. In itself, or as relates to its own intrinsic qualities, it is a thing but of small value. Gold and silver, or the precious metals, of which money is usually made, are chiefly brought from the mines of South America, and are commercially valued according to the cost of their production and their supply and demand, as is the case with every other object in trade. If an over-abundance of any of these metals be easily obtained, and the demand be not increased, the value is immediately lowered; and if the supply is obtained with difficulty, while the demand remains steady or is increased, the value is heightened. It cannot be too strongly impressed on the mind of the reader, that money is but a metallic representative of something which has been given for it. To a misunderstanding regarding this apparently very simple circumstance, much human misery may be attributed. It has too often been the feeling of communities, that if they possessed gold they possessed riches, and not a mere article for facilitating commerce—an article which, from its uses in this respect, is itself a commodity. The most startling illustration of this fallacy is to be found in the history of Spain. Before the working of the gold mines in their American possessions, the Spaniards were a rich and prosperous commercial people; but when they began to find gold, they thought they had got at their hand that for which they formerly laboured, and that, like a poor industrious man who has unexpectedly succeeded to an estate, they need now work no longer. To prevent their riches from disappearing, the law prohibited the exportation of the precious metals, and thus effectually shut the door against the only way in which they could be made sources of wealth—exportation as an article of commerce. In that view, and in that alone, was there any advantage in the possession of gold; and even had it been employed in the most advantageous manner, it would not have been so profitable as many other means of employing capital and labour; for, as already remarked, the peculiarity which makes gold so useful as a measure of value, is, that the labour expended in producing it bears so constant a ratio to the quantity realised, that but small profits are made from its production.

The manner in which the Spaniards became acquainted with the treasures of South America tended to nourish the hallucination. They found a considerable quantity of gold in the possession of the natives, which they speedily seized. They found also native gold in the streams. Thus, by an accidental circumstance, such as that of finding a hidden treasure, they became possessed of money without working for it. They did not reflect that, if this lasted, gold would cease to be the representative of value which it was, and would be of no further service in commerce than as an extremely beautiful material for manufactures, which would fluctuate in value with the tide of fashion. When they could procure the mineral only by the result of hard labour, they still had the same preposterous feeling that they were possessed, not of the means of making wealth but of wealth itself, and dearly did they pay the penalty. While starvation desolated the land, and the highest grandees could not command so much of the produce of ordinary commercial industry as a glass window, every wretched dwelling glittered with mountains of plate.

Gold, it is necessary to repeat, is simply a commodity—a commodity which we import: and if we can export it profitably, why not do so? If the country in question will take nothing from us but gold, then it is either worth our while to buy gold for the purpose of sending

* Smith's Wealth of Nations, book I. chap. 4.

to it, or it is not. If it is not worth while, then the trade will not be carried on at all. If it is worth while, then the trade is on the whole a profitable one. If we import sugar from the Spanish settlement of Manila, and export it to Germany, this is called "the carrying trade," and quite correctly; but it seems to be thought that if we import gold from South America, we must keep our hands upon it, otherwise we shall be ruined. It is commonly said that we can only establish a profitable trade when we pay in our own manufactures. Now, paying in gold is, after all, indirectly paying with our own manufactures, for (except the comparatively trifling quantity that may have been taken in war) there is not an ounce of bullion in the country that has not been obtained in exchange for some article produced either by our manufacturing or agricultural industry. Let him who doubts this position try if he can discover any other method by which gold can have found its way to this country.

Coined Money.—Gold and silver, as we have said, are chiefly brought from the mines of South America. They are generally imported in the form of bars, and in this rude state are commercially named *bullion*. The price of bullion in the market is liable to fluctuations, according to the cost of production, the supply, and the demand. However, the variation is never very great, and has little sensible effect on the coinage. It is customary to estimate the purity of gold by an imaginary standard of 24 carats.* If in a piece of gold weighing 24 carats there be 1-24th of alloy, then the piece is 1 below the standard. What is called jewellers' gold is seldom purer than 20 fine to 4 of alloy—the alloy being usually silver, but sometimes copper, which gives a deeper red tinge to the metal. Perfectly pure gold is never seen either in trinkets or coins, for it is too brittle to be wrought alone, and requires a little alloy to render it malleable. Sovereigns, and other modern English gold coins, contain one-twelfth of alloy, but this twelfth is not reckoned as gold, in point of value. At present the gold coin of Great Britain is issued at very nearly its precise market value as bullion. A pound weight of gold, of 22 carats' fineness, produces coins to the amount of £46, 14s. 6d., which is about the price at which bullion sells for in the market. Thus the gold of our currency is coined free of expense. In coining silver, government is allowed, by the act 56 Geo. III., a profit or seigniorage of about 6 per cent.; the pound weight of silver, which should produce 62 shillings, being coined into 66 shillings. Our silver coins being therefore of a little less real value than the sums they represent, they are not liable to be melted down by silversmiths for the manufacture of articles in their trade.

Till the year 1816, on the occasion of a new coinage, the silver shilling was the standard of money, though, for convenience, the pound of twenty shillings was the principal sum named in commercial transactions. The act 56 Geo. III. rendered gold the principal standard, and made silver subsidiary to it; since which period no more than forty shillings are a legal tender, that is to say, no one is bound to accept of more than forty shillings in silver in payment of any debt or demand. The legal tender, above forty shillings, is in sovereigns; but in point of fact an order on the Bank of England is considered equivalent.

The copper coinage, consisting of pennies, halfpence, and farthings, is issued from the mint at the rate of £224 per ton, being more than 100 per cent. above its market value; in other words, a penny piece is intrinsically worth no more than a halfpenny. Formerly, the pieces usually known as old pennies were larger; but, in consequence of a rise in the value of copper in 1806, it has since been thought advisable to adopt the rate above mentioned. Between 1815 and 1836,

there was an issue of copper money to the value of £180,107, 4s.

The coined money of Great Britain is the most elegantly executed, and among the purest in the world. The greater part of the continental coinage is poorly executed and basely alloyed. In Holland, and most of the German states, the coins legally current as silver money are apparently one-third brass, and resemble the counterfeit shillings and sixpences of a former period in England. In France and Belgium, the new gold and silver coins are handsome, and so likewise are the large gold and silver pieces of Prussia. The coins and medals executed by direction of Napoleon in France are in a high style of art.

Money of the current and standard coinage is frequently signified by the term *sterling*, as "one pound sterling," &c. With respect to the origin of the word *sterling*, there are three opinions. The first is, that it is derived from Stirling Castle, and that Edward I. having penetrated so far into Scotland, caused a coin to be struck there, which he called *Sterling*. The second opinion derives it from the figure of a bird called *stirling*, which appears about the cross in the ancient arms of England. The third most probably assigns its true origin, by deducing it from *Esterling*; for in the time of Henry III. it is called *Moneta Esterlingorum*, the money of the Esterlings, or people of the East, who came hither to refine the silver of which it was made, and hence it was valued more than any other coin, on account of the purity of its substance. The denomination of the weights and their parts is of the Saxon or Esterling tongue, as pound, shilling, penny, and farthing, which are so called in their language to the present day. The term *sterling* is now disused in England in all ordinary transactions, but is still used in Scotland to distinguish sums from the ancient money of the country, as referred to in old deeds and notices of pecuniary transactions. The old Scots money, previous to the Union of 1707, was in pounds, shillings, and pence, but these were only a twelfth of the value of sterling money of the same denomination; thus, a pound Scots was only twenty pence sterling. The word *sterling* is also in use in the colonies, to distinguish the legal standard of Great Britain from the currency money in these places.

The following is a short explanation of the origin of the principal terms used in reference to coined money. The word *money* is from the Temple of Juno *Moneta*, in which money was first coined by the ancients. *Pecuniary* is from *pecus*, a flock—flocks and herds of animals being originally equivalent to money, or things constituting wealth. *Cash*, in commerce, signifies ready money, or actual coin paid on the instant, and is from the French word *caisse*, a coffer or chest in which money is kept. *Pound* never was a coin; the term was originally employed to signify a pound weight of silver, but afterwards it was applied to mean twenty shillings in tale, or by counting. *Guinea* took its name from the coast of Guinea in Africa, whence the gold for it was originally brought; at first, the piece was current at twenty shillings, afterwards it was equal to 21s. 6d., and finally settled at 21s. In the present day the guinea is not coined, and the term only remains to indicate 21s. Honorary fees and gifts are still usually reckoned in guineas, though paid in other money. *Shilling* and *penny* are both from Saxon words; the penny was first coined in silver. *Groat* was a name given to silver pieces equal to four pennies in value, coined by Edward III.; the word groats is a corruption of *grosses* or great pieces, and was given to distinguish this larger coinage from pennies or small coins. *Farthing* is a corruption of *fourthing*, or the fourth part of a penny.

A currency of coined gold is the most secure and permanent, and the pieces are received for their proper value in all countries. But notwithstanding these advantages, a metallic currency alone is quite unsuitable in highly commercial communities. There is no adequate importation of the precious metals, at the ordinary value, to supply material for a purely metallic

* The carat is a small weight of universal use, containing four grains. It originated from the carat or kaura, a small bean, used by the Abyssinians for weighing gold. Diamonds are also weighed by it.

currency; and if it were possible to provide a sufficient supply, the inconvenience and risk of loss to individuals from using coins only in all mercantile transactions, would be too great to be patiently borne. A heavy loss would also be incurred annually by government from tear and wear, which it would be impolitic to avert by imposing a proportionate seigniorage. In these and other points of view, a currency of metal only would be exceedingly unsuitable to the existing condition of society and commerce in Britain. Something else requires to be employed as a medium of exchange and representative of the enormous sums which are daily transferred from one to another all over the country.

Paper Money.—The deficiencies of a metallic currency are compensated by the use of paper money. Paper money is in the form of small pieces of paper, each purporting to be an obligation or promise to pay a certain sum which is specified upon it. Whether passing by the name of a bank-note, a promissory-note, or bill of exchange, the principle on which it is issued is the same—an express obligation on the issuer to pay the specified sum in coined money on demand, or at a certain date which is mentioned. The notes of this kind issued by a bank pass from hand to hand, any holder having it in his power at any time to demand fulfilment of the obligation from the bank; but in the case of a bill of exchange, which is a promise by a private party, it is presentable for payment only at a specified period.

Bank-notes and bills together constitute the paper currency of the country, and are of prodigious use in carrying on commercial transactions. It is calculated that while the metallic currency seldom exceeds three millions, the paper currency, or amount of negotiable paper in circulation, is perhaps two hundred millions: of bank-notes alone, the circulation in the united kingdom may be reckoned to be sixty millions.

Bills of Exchange were first used for the purpose of settling pecuniary transactions between individuals at a distance from each other, and were therefore convenient expedients to avoid the risk of sending actual money to a creditor. This may be explained as follows:—If A, a merchant in London, have a debtor B and a creditor C, both in Paris, instead of sending money to C, and getting money sent to him by B, he may give C an order on B to pay the debt over at once to him. This is a bill of exchange in its simplest form. Suppose, however, that A has a creditor in Paris, but no debtor, while his neighbour E has a debtor, but no creditor: A may pay the money to E which the French debtor owes him, and obtain from him an order on his debtor to pay A's French creditor. This order he will be said to purchase. It will be an accommodation to him or to the other party, according to circumstances. In the complicated arrangements of modern commerce, the individual debtors and creditors are lost sight of. If a person has a sum to transmit to another country by such an order, the rate at which he will obtain it will depend on the pecuniary relations of the two places taken in the main. If there is more money payable at the moment by people in London to people in Paris, than there is payable by those in Paris to those in London, there will be a demand for orders on Paris, and a premium will be payable for the accommodation by those who want them. In this case, the *exchange* will be said to be against London. In Paris, on the other hand, there will be more people ready to give such drafts than there are in want of them, and those who dispose of them must do so at a discount. The rate of exchange is from this circumstance said to be in favour of Paris. The premium in the one case, and the discount in the other, will be measured by the balance due by London to Paris over what is due by Paris to London; and the principal sum to be met by the rate of exchange will be the expense of transmitting that balance in specie, unless the accounts can be adjusted by bringing transactions with some other community into the circle.

We may vary this explanation of the principle of

exchange as follows:—Great Britain, like every other country, is exposed to a drainage of its metallic currency, by the balance of trade falling against it. As long as our exports are equal to our imports, they will balance each other; the bills drawn in England against foreign countries will be balanced by bills drawn in foreign countries against England. In this state of things, the exchange is said to be at *par*, or even. If our exports exceed our imports, then foreigners must send actual money for the overplus, because they have not occasion to remit bills for the amount. If our imports exceed our exports, we must, in the same manner, remit the overplus in actual money. Thus, a dearth and scarcity of corn in England will cause a drainage of the precious metals, because our imports of that article rise to a large amount, or much beyond the value of goods exported. The exchange is then said to be against England.

The multifarious transactions taking place between merchants in Britain and America, cause an incessant process of payment by the intervention of bills of exchange, many thousands of pounds being paid away daily in their accounts with each other without the aid of any metallic money, except a few coins for small odd sums.

The following is a common form of drawing a bill of exchange:—

£100. London, 5th August 1840.
Three months after date, pay to me or my order the sum of one hundred pounds, value received.
To Mr THOMAS STYLES, Merchant, JOHN NOKES.
Cripplegate, London.

The bill being drawn in this form, Mr Styles *accepts* it, by writing his name either below that of Mr Nokes, or across the face of the writing. Mr Nokes, who is called the *drawer*, now endorses the bill, by writing his name on the back of it, and thus the bill becomes *negotiable paper*. It may be paid away to a third party; and he endorsing it below Nokes's name, may pay it away to a fourth; and he endorsing it in the same manner, may pay it away to a fifth; and so on. Thus the bill may pass from hand to hand, on each occasion liquidating a debt of £100, till the day of payment by the original acceptor arrives, when it is duly presented by the last holder. Instead of running this course, the bill may at any period be *discounted* by a bill-broker or banker. The discounting of a bill consists in giving the money for it, less a certain sum for *interest*. Interest is a charge for the loan of money, and is ordinarily reckoned by *per cent*. Thus five per cent. (or centum) per annum, signifies a charge of £5 for every £100 for one year, which is equal to a shilling for each pound. This is legally the highest interest which can be charged. When, therefore, a bill for £100 for three months (or fourth part of a year) is discounted at five per cent. interest, a charge equal to the fourth part of £5 is made by the discount, and this is his profit for the loan of the money for that period. Interest for a single day on any sum may be easily calculated by a rule in arithmetic; but merchants and bankers, for the sake of expedition and correctness, generally consult a set of printed interest tables.

According to a practice of old standing, bills are not presentable for payment till the third day after that which is specified for them to fall due. The three days allowed are called the *days of grace*. Thus, a bill drawn on the 5th of August, at three months, is not legally due till noon of the 8th of November. In some countries the period of grace is much longer than three days.

Bills of exchange are occasionally drawn in the form of promissory-notes; as, for example:—

£100. London, 5th August 1840.
Three months after date, I promise to pay to Mr John Nokes, or order, the sum of one hundred pounds, value received.
THOMAS STYLES.

When in this form, no signature is written across the

front of the document—it is only endorsed by the creditor. Promissory-notes are in every respect liable to the same regulations as bills. Both promissory-notes and bills must be written on stamps of the proper price; if on stamps of an inferior value, they are not negotiable and cannot be protested. The protesting of a bill is simply the marking of a notary-public that it has not been duly paid on presentation; which marking, or *noting*, forms the warrant for the issuing of legal diligence by the competent authorities. If not protested on the day it has fallen due, this step cannot be taken afterwards, and the bill remains a mere evidence of the debt, to be produced in the course of a regular and perhaps tedious prosecution. Men in business are careful to present their bills for payment on the exact day they become due. When the acceptor of a bill fails to pay the amount, the holder can fall back for payment on any of the endorsers, or the drawer.

Bills are sometimes drawn at *sight*, or so many days after sight; for example:—

£50. London, 5th August 1840.
One day after sight, pay me or my order the sum of fifty pounds, value received.
To Mr ISAAC WALTERS, JOHN JENKINS.
Cheapside.

A bill of this kind is usually drawn by a person at a distance from his debtor, and on writing it out and endorsing it, he transmits it to an agent (or probably a creditor of his own) in the town in which the debtor resides. The agent having received it, hastens with it to the debtor to be *sighted*, which consists in the debtor, as for instance the above Mr Walters, accepting it by signing his name and marking the day on which he has done so. The bill is now a negotiable instrument, and on the third day after the day specified, it is presentable for payment. This may be called a convenient way of getting ready money or prompt payment of any sum from a debtor. It is very common to draw foreign bills of exchange at so many days after sight. These bills are of precisely the same nature as inland or home bills of exchange; but, for the sake of security in transmission, they are drawn in sets of three. The following is a common form:—

£100. Montreal, 18th June 1840.
Sixty days after sight, pay this my first bill of exchange (second and third of the same tenor being unpaid), for the sum of one hundred pounds sterling, value received.
To Messrs BROWN and JONES, SAMUEL ROBERTSON.
Merchants, Bristol.

This bill being endorsed by Mr Robertson, is transmitted to England (probably in liquidation of a debt of the same amount), and is presented to Messrs Brown and Jones to be sighted, and is afterwards presented to them for payment accordingly. The agent or individual to whom it is sent, receives by the next packet the second bill of the same tenor. Should the first have been lost by shipwreck, this second is available, but otherwise it is of no use, and may be destroyed. The third bill of the same tenor is retained by the drawer till he learn whether the first or second have been received; if both have been lost, it is transmitted. Bills of this description are rarely sent by the actual drawer. They are usually paid away or sold on the spot to another party, who transmits them to a creditor of his own, and he negotiates the payment.

Bills of exchange serve three useful purposes in commerce. 1. A bill puts a debt in a tangible form: for example, instead of leaving a debt of £100 to be paid at an indefinite period, so as to protract its settlement, let it be put in the shape of a promise to pay, and the creditor becomes satisfied that he now possesses the power to compel payment at a certain and not very distant period. 2. A bill is a negotiable instrument. If the parties be trustworthy, it may be discounted for cash; and thus, while the creditor will receive his money, less

a trifle for discount, the debtor is left unmolested till the final day of payment. 3. A bill is a convenient representative of money, which may be sent from place to place in a letter, and if accidentally lost, its payment may be stopped and a new bill forwarded to its destination.

BANKS.

Origin of Banks.—The term *bank*, in reference to commerce, signifies a place of deposit of money, and is derived from the Italian word *banco*, a seat or bench, the first custodiers and dealers in money in Italy having been Jews, who sat on benches in the market-places of the principal towns. It is worthy of remark, that in the infancy of almost all modern civilised nations, the earliest money-dealers were Jews, and in the present day persons of that nation are the chief commercial negotiators in barbarous countries. Their acute intelligence, patient industry, and disregard of local attachments, have in all ages fitted the Jewish people for this course of life.

About the reign of Charles I., Jews and goldsmiths, to whom valuable property had been assigned for safe custody, began to exercise the profession of bankers in England; but till a much later period there were several eminent bankers in London who still kept goldsmiths' shops.

On the continent of Europe regular banking commenced much earlier than in this country. The Bank of Venice was established as early as 1171, the Bank of Amsterdam was begun in 1609, and that of Hamburgh in 1619. Regular banking establishments were formed in England and Scotland shortly after the Revolution. The Bank of England began in 1694, and the Bank of Scotland in 1695, since which period banks have been instituted in all the principal towns in the united kingdom.

Business of Banking.—A bank is a commercial institution, established and conducted by private individuals for their own behoof, or by joint companies. Like a merchant's counting-house, it consists of various officials—a manager, cashier, clerks, &c., including tellers, or persons for receiving and paying out the money. Banks are usually reckoned to be of two kinds—banks of *deposit* and banks of *issue*. By deposit it is meant that the bank takes charge of deposits of cash, which it is ready to restore on demand. Some banks of this nature allow interest on the sums received, and others do not do so; all, however, of necessity, make use of the money so deposited, by lending it out at a certain rate of interest, and thus compensate themselves for their trouble. The loans are most commonly in the form of discounts of bills, and occasionally advances on heritable property, or other securities. Banks of issue transact all the ordinary business of banks of deposit, and in addition issue notes of their own instead of actual cash or the notes of others. Almost all banks in this country are banks both of deposit and issue; they at least issue notes as far as the law allows them, which is to the extent of notes of £5 in value and upwards. The only banks permitted to issue below £5 are those in Scotland, for which a peculiar law exists.

Although banks are thus at liberty to issue notes to any extent, it is not to be supposed that they do so without a certain degree of restraint. The expense of manufacturing notes, notwithstanding that each requires a stamp, is a comparatively small check; the main restraint on over-issuing consists in the obligation to pay the sum which the note expresses, on demand. When, therefore, a banker discounts a bill for £100, and gives out one hundred notes of one pound each, he encounters the risk of having these notes returned upon him, and a demand made for them in cash within the compass of a day or two thereafter. This risk is increased by the practice among bankers of never issuing the notes of others. They are anxious enough to push

forth on a safe principle their own paper, but when they receive deposits or payments in the paper of another bank, they use all convenient speed in demanding cash from that bank in exchange for its notes. The notes of any given bank being received purely on a principle of good faith or credit, it is of great importance that the bank should do nothing to incur the suspicion of being incapable of retiring its notes. When any suspicion of this nature arises, the public, who are ignorant probably of the true circumstances, rush to the bank for gold in exchange for its notes. This kind of panic is called a *run*. Bankers are always naturally anxious to issue their notes to as great an extent as is consistent with safety to the institution. The measure of this safety is the extent of capital at command to liquidate demands for cash. To accommodate the amount of this capital to the probable necessities of the case, is the point in banking for which the greatest skill is required, because if much capital is kept lying useless in the coffers of the bank, there is a loss of interest which may be ruinous, whereas, if too little is retained, a sudden run might utterly destroy the credit of the concern. When banking is managed with prudence, there is a certain amount of money kept at interest in the funds or government securities, upon which, if need be, an order is given. Thus a safety fund is established, whereon to fall back in case of emergency. A share of the subscribed and paid-in capital of the shareholders of the bank forms this safety fund; and it may be taken as a general rule, that where a bank is provided with no such security, but issues notes on the faith of the fund it may chance to have in hand, then that bank is trading on a principle alike dangerous to itself and the public. A banker who unites enterprise with prudence takes every available means to extend the circulation of his notes in as minute and distant channels as possible; for as long as a note is out, an interest is being received for the capital which it represents. In other words, when a pound note is out, it represents a sovereign which has been deposited or given for it, and which sovereign is employed in a fund in some manner of way at interest, for the advantage of the banker.

On considering the various operations connected with banking, it will be found, that, independently of the impulse and elasticity created by the facilities given to commerce, the direct and primary effect of them is the employment of waste money. A bank gathers, as it were, the money of a district into its hands, and, allowing each man to use as much of his own share as he requires at the time, keeps the remainder likewise in employment, which it would not have been had it remained in its owner's hands.

The rapidity with which all kinds of payments are made, and therefore the frequency with which money can be used, through the instrumentality of banks, form their most striking feature. In a bank office the same sum of money will have been made the means of paying its amount a dozen of times over in a day without being once uplifted. A, who is due B L.100, gives a cheque for the sum, which will make it stand in his name instead of A's. B gives a similar cheque to C; C to D; and so on. "The transfer of lodgments," says Mr Gilbert, "is extensively practised in our own times. If two persons, who have an account in the same bank, have business transactions with each other, the debtor will pay the creditor by a cheque upon the bank. The creditor will have this cheque placed to his credit. The amount of money in the bank remains the same; but a certain portion is transferred into a different name in the banker's books. The cheque given by the debtor is an authority from the debtor to the banker to make this transfer. Here the payment between the creditor and debtor is made without any employment of money. No money passes by one to the other: no money is paid out or received by the banker. Thus it is that banks of deposit economise the use of the circulating medium, and enable a large amount of transactions to be settled with a small amount of money. The money thus liberated is employed by the banker in various

advances, by discount or otherwise, to his customers. Hence the principle of transfers gives additional efficacy to the deposit system, and increases the productive capital of the country. It matters not whether the two parties, who have dealings with each other, keep their accounts with the same banker or with different bankers, for as the banks exchange their cheques with each other at the clearing-house, the effect, as regards the public, is the same."^{*}

London, in which the government funds are managed, and where all the great pecuniary transactions of the empire may be said to centre, furnishes a remarkable instance of the economising of money by the interchanging of cheques or drafts among bankers. Each banking house in the metropolis sends daily the drafts it has received on other banking institutions to a place of common resort, called the clearing-house. Here a clerk from each bank attends and exchanges drafts. It is understood that the accounts balanced every day at this clearing-house amount to eight millions sterling, the settlement being effected by the intervention of only about L.250,000 in notes and cash.

Bank of England.—This institution, which is the largest and most important banking establishment in the world, was projected by William Paterson, a Scotchman, and received its charter of incorporation July 27, 1694. It was constituted as a joint-stock association, with a capital of L.1,200,000, which sum was lent at interest to the government of William and Mary, at the time in a state of embarrassment. At its very outset, therefore, the Bank of England was a mere engine of government; and in a lesser or greater degree it has enjoyed this character through all the stages of its subsequent history. According to its charter, the management is committed to a governor, lieutenant-governor, and twenty-four directors, elected by stockholders who have held L.500 of stock for six months previous to the election. A director is required to hold L.2000, a deputy-governor L.3000, a governor L.4000 of the capital stock. At first the charter of the bank was for only eleven years; but in consequence of the great services of the institution to government, its charter has been at various times renewed. The original stock of L.1,200,000 has been augmented at different times, till, in 1816, it reached L.14,553,000 upon which the stockholders drew dividends. The profits of the bank arise from traffic in bullion, discounting of bills, interest on mortgages, allowance for managing the public debt, &c.

The net profit of the bank in 1832, out of which interest was paid on the capital stock, was L.1,189,627. The interest paid to stockholders has wavered from five to ten per cent. per annum, but has more generally been about eight per cent. The bank has besides, at different times, made dividends under the name of *bonuses*. A bonus is a sum of money derived from the division of a fund, which had been suffered to accumulate or remain for use, in case of an emergency. The emergency being past, the fund is divided. The bonuses of the Bank of England have varied from ten to five per cent.

Originally, the business of the Bank of England was conducted at Grocers' Hall, in the Poultry; but about a century ago it was removed to a new edifice near the Royal Exchange, which may be described as the centre of the great business district of London. With numerous extensions, the bank structures cover an area of about eight acres of ground. The principal entrance is by Threadneedle Street, a thoroughfare immediately to the north of the Royal Exchange. Within the limits of the bank are conducted, on an extensive and perfect scale of art, the various processes of printing notes and other documents for the establishment; and in the fire-proof vaults beneath is the repository of bullion, or bars of gold and silver and coined money, constituting the substantial stock of capital for the time being. The number of clerks, porters, and other officials employed in the establishment, was lately about 900.

^{*} History and Principles of Banking, pp. 123, 124.

The Bank of England trades not only on its paid-up capital, but on the capital confided to it in the form of deposits, and usually called its liabilities. This is perfectly legitimate, and consistent with the true principles of banking, it being only necessary to take care that the institution always leaves itself a sufficient fund from which to satisfy all demands. The issue of notes by the bank is understood to be somewhat in accordance with the amount of its deposits; but this is necessarily dependent on various contingencies in public affairs. The leading feature in the character of the institution is the circumstance of its acting as the banking-house for the government. All the money drawn in the form of taxes or otherwise for the public service is consigned to the bank, while all drafts for the public service are likewise made from it. In carrying on this branch of its business, the bank allows the government to overdraw its account, that is, to take a loan of cash to a certain amount. The money so lent was some time ago upwards of L.14,000,000, which parliament made a provision to reduce and finally pay off. The important services rendered to the government, have in past times secured to the bank most valuable privileges, amounting almost to a monopoly of the business in money. In 1797, when the bank found itself unable to meet a run made upon it for gold for its notes, the government of that day summarily protected it from bankruptcy by issuing an order that Bank of England notes should be considered a legal tender; consequently, the holders of notes at the time were, by force of law, refused their value in cash. This extraordinary state of affairs, with various modifications, lasted till 1821, when cash payments were resumed. Meanwhile, the notes of the bank, from not being representatives of specie, were considerably depreciated in nominal value; so great was the depreciation at one time, that four pound notes would have been given in exchange for three guineas. It has been frequently represented as a serious hardship, that debts contracted during this prevalence of a depreciated currency, have had to be paid in a currency of full value; for by this means the creditor receives perhaps a third more money than the actual value of the original sum owing.

Joint-Stock Banks in England.—A parliamentary return was published early in 1840, relative to these establishments, from which it appeared that the number of joint-stocks in England, at 1st January 1840, was 108, a considerable proportion of which had been instituted within the preceding ten years.

The number of partners in these banks varies from 50 to 1200, and may average about 300. There are half-a-dozen with less than fifty partners, the smallest number being seven. Fifty-eight of the banks have branches, and fifty have none. The branches, including the parent bank, are from two to sixty-seven in number. There are eight banks which have more than twenty branches. The whole number of parent banks and branches is 658.

There are besides about 550 *private banks* in England, that is, banks having not more than six partners. Adding these to the joint-stock banks and their branches, the whole number of banking establishments will be about 1200.

The issues of the joint-stock banks, when contrasted with the magnitude of the establishments, seem to us exceedingly small. According to the last return (August 2, 1839), the notes in circulation of all the joint-stock banks were in value L.4,665,110. This, divided by the number of banks (108), gives an average circulation of only L.43,200 for each; or, if we include the branches, the average for each office or establishment is only L.7000. Supposing the money to be employed in discounting at five per cent., the annual profit on L.4,665,000 would be only L.230,000, or no more than L.350 to each establishment. It is evident that their profits must be chiefly derived from deposits, which they can employ at five per cent., while, we believe, they give only two.

The issues of the *private banks*, by the same return,

were L.7,610,700, which gives an average of about L.14,000 for each establishment. It appears that the joint-stock banks, so far from superseding the private banks, have had but a very slight effect in narrowing their issues.

The chief advantage conferred on the Bank of England, and constituting its charter of monopoly, is the privilege of being the only bank in London, or within sixty-five miles of it, having more than six partners, which can issue notes payable to the bearer on demand. The bank has also the privilege of its notes being a legal tender by other banks for any sum above L.5, so long as it pays its notes in cash on demand. This provision is a security to all other banks against the effects of sudden runs upon them for gold. It is ordained by act of parliament, that "upon one year's notice, given six months after the expiry of ten years from the 1st of August 1834, and upon repayment by parliament of all sums that may be due from the public to the bank at the time of the expiration of such notice, the exclusive privileges of banking granted by this act shall cease and determine at the expiration of such year's notice." Hence, in 1844-5, there will necessarily be a renewal or modification of the peculiar privileges of the Bank of England.

Stocks—Stock Exchange.—There are various kinds of stocks. Shares in a joint-stock company are called stock, and so are shares of debts due by government. It is the last-mentioned stock, which is variously termed *public securities*, or the *funds*, that requires to be explained, and in doing so we take the liberty of using the definition of a popular writer.*

"In every war in which this country has been engaged since the Revolution, the amount of the annual taxes has been found inadequate to defray the expenses of government. To supply the deficiency, our rulers have generally had recourse to loans—that is to say, they have borrowed money from such individuals as were able and willing to lend it, giving these individuals a security for the payment of a certain annual interest. To explain the nature of this transaction, I shall take a very simple case. Suppose, then, that L.100 is the sum which government wishes to borrow, and that an individual offers to lend that sum at an interest of 5 per cent. On paying down the money, the lender receives a bill, bond, or acknowledgment, for the amount; by which acknowledgment he is entitled to draw yearly from the public revenue L.5 of interest, but on the express condition that he is not to demand repayment of the principal, or sum lent, unless government is willing to repay it. The person who thus possesses the bill or acknowledgment is said to be a *holder of L.100 of 5 per cent. stock*, and the money lent upon that bill constitutes a part of what is called the *national debt*, because it is in fact borrowed by the nation, and the interest is paid out of the taxes. It is obvious, however, that few persons would be disposed to lend money on the condition of never being allowed to demand repayment, even though they were quite certain of receiving annual interest, and of transmitting the right to that interest to their posterity. To remedy this inconvenience, therefore, the lender who wishes to employ the sum which he lent to government in any other way, though he cannot directly demand repayment, is at liberty to sell his bill to any body who will purchase it, and for any sum that another may be willing to pay for it. In doing so, he merely sells to a second person the right which he himself possessed to the annual interest of L.5, and that second person is of course at liberty to dispose of his right to another in the same way. This transaction, in general, is called a *transfer of stock*; and in the particular case which I have supposed, the one is said to sell, and the other to buy, L.100 of 5 per cent. stock. If 5 per cent. be considered as a fair and equitable interest for money lent, it is obvious that such a bill as I have now been speaking of, or, in other words, that L.100 of 5 per cent. stock, is just worth L.100 sterling. It is possible, however, that

* Blackwood's Magazine: 1818.

in certain circumstances the holder of that bill may receive more, or be obliged to take less for it than L.100. If two or three individuals, for example, have each a sum of money, which they are anxious to lay out at interest, but find it difficult to do so, a competition will naturally take place among them to become the purchaser of the bill in question, which will always secure to the holder L.5 of yearly interest. The possessor of the bill will of course take advantage of this competition, and raise his price, say to L.105. The purchaser, therefore, pays L.105 for L.100 of 5 per cent. stock, or he lays out his money at an interest of L.5 for every L.105, which is at the rate of something more than 4 $\frac{3}{4}$ per cent. If, on the other hand, however, the possessor of the bill or stock is anxious to dispose of it, while few are willing to buy it, he will be forced to offer it for less than L.100, say L.95. The purchaser, in this case, pays L.95 for L.100 of 5 per cent. stock, or he lays out his money at an interest of L.5 for every L.95, which is at the rate of something more than 5 $\frac{1}{4}$ per cent. For simplicity of illustration, I have supposed that L.100 is the sum borrowed by government, and that of course there is just one bill to be disposed of, or transferred by the lender. If it be supposed, however, as is really the fact, that the loans generally amount to several millions, the necessity which the lenders are under of selling their bills, or, in other words, transferring their stock, will be more apparent. The transaction between government and the lenders is precisely the same in the case of millions as in that of a hundred; and it is unnecessary, therefore, again to illustrate the general principle of that transaction. It is evident, however, that even the most opulent merchants, who are generally the lenders, cannot be supposed to have such a command of money as to be able to advance ten or twelve millions to government at once. When they contract for a loan, therefore—that is, when they agree to lend to government the sum required—they generally pay the money by instalments, or partial payments at certain intervals, say one million a-month, till the whole is advanced. In the mean time, they sell or transfer the bills or securities which they receive from government to those who may have money to lay out at interest, and who of course will be disposed to purchase such bills, so that the sale of the bills of the first instalment may enable them to pay the second. In this way, government securities or bills become articles of commerce, and their price is regulated, like that of any other article, according to the supply and demand.

It is easy to see how the price of stock is liable to fluctuation from accidental circumstances. I shall not attempt to enumerate these: but it may be worth while to point out how it is affected by peace and war, as these two conditions of the country are generally found to have the greatest influence in raising or depressing the value of stock. In the time of war, then, the price of stock is comparatively *low*, because, in such a state of things, it is likely that government will be under the necessity of borrowing; and as every loan produces new bills, the quantity of those to be disposed of, or, in other words, the supply of the market, will be increased. The price, therefore, will fall, for the same reason that the price of corn falls after a plentiful harvest. In time of peace, again, the price of stock is comparatively *high*, because, in such a state of things, the taxes are likely to be sufficient to defray the expenses of government without any loans, and consequently no new bills are to be disposed of, or the supply, though not positively diminished, ceases to be augmented. For the same reason, the price of stock in the time of war is materially affected by the nature of the intelligence that comes from the scene of action. If that intelligence be unfavourable, stock will fall, because there is a prospect either of protracted warfare, or of the necessity of more vigorous exertions on the part of government; in both which cases new loans may be necessary, and consequently a new supply of bills will be thrown into the money market. On the other hand, should the intelligence be favourable, the price of stock will rise,

because the prospect of a successful termination of the war renders it probable that there will be no new loan, and consequently no new supply of stock.

It is this variation in the price of stock that gives room for the nefarious practice of *stock-jobbing*. That practice consists in raising and circulating reports calculated to raise or depress the price of stock, according to the particular views of the individual. If he wishes, for example, to sell his stock or bills, he endeavours to propagate some report or other favourable to the issue of the war, and the establishment of peace, in order, if possible, to raise the price of stock; and, if he wishes to buy, he propagates reports of a contrary tendency. It is painful to think that this abominable system is sometimes carried on by men whose rank and station in society, to say nothing of the obligation of morality and religion, might be expected to place them far above any such disgraceful acts; but, in general, I believe it is confined to men of desperate fortune and little character; who subsist by a species of gambling, to which the finance system of this country has opened a wide and extensive field. I allude to those men who make a practice of buying and selling stock, without actually possessing any, and whose transactions, therefore, are nothing more than wagers about the price of stock on a certain day. To explain the nature of the transaction by an example: I shall suppose that A sells to B a government bill of L.100, or L.100 of 5 per cent. stock, to be delivered on a certain future day, and that the price is fixed at L.102. If, when the day arrives, the price of stock shall have fallen to L.100, A would be able to purchase the bill in question for L.100, while, in consequence of his bargain, B would be obliged to pay him L.102 for it, so that A would gain L.2. If, however, stock had risen to L.104, B would still be obliged to give only L.102, so that A would lose L.2; but instead of actually buying and selling the stock, the bargain is generally implemented by A paying to B, or receiving from him, the L.2, or whatever may be the sum of loss or gain. In such a case as this, it is obviously A's interest that the price of stock should fall, and as obviously B's interest that it should rise, between the day of the bargain and that of settling; and hence the temptation held out to both to circulate reports favourable to their own particular views. B, or the buyer, is usually denominated a *Bull*, as expressive of his desire to *toss up*; and A, or seller, a *Bear*, from his wish to trample upon or *tread down*. The law, of course, does not recognise a transaction which proceeds on a principle of gambling; but a sense of honour, or, what is perhaps nearer the truth, *self-interest*, generally secures the payment of the difference, as the person who refuses to pay his loss is exhibited in the Stock Exchange under the designation of a *lame duck*, a disgrace which is considered as the sentence of banishment from that scene of bustle and business."

In the preceding remarks, the loans to government have been supposed to be negotiated in bills bearing five per cent. interest; practically such is not the case. The stocks, from a variety of circumstances, are of different denominations, some having been created at one rate of interest or profit, and some at another. The principal stock is called the three per cent. consolidated fund—that is, several borrowings consolidated into one debt at three per cent. This stock is usually called, for shortness, three per cent. consols. Another stock is called three per cent. reduced annuities, or briefly, three per cent. red. an. The three per cent. consols embrace a debt of upwards of L.300,000,000, or nearly one-half of all the money due by the nation; and in most instances it is a share of this debt which people purchase when they buy into the funds. In 1839, the debt, funded and unfunded, amounted to L.763,803,563, the annual charge or interest upon which, to be raised by taxation, was L.28,669,333. It was ascertained that this interest was payable to 279,751 persons, fully two-thirds of whom received under L.50 each.

Banks in Scotland.—The earliest banking institution in North Britain was the Bank of Scotland, instituted

by a charter of incorporation from the Scots parliament in 1695. The original capital was £1,200,000 Scots, or £100,000 sterling. The amount was raised by shares differing in extent, from £1000 Scots, or £83, 6s. 8d. sterling, to £20,000 Scots. In 1774, the amount of stock was extended to £200,000 sterling; and now it is a million and a half sterling. The shares are now £100 sterling each.

The establishment of the Bank of Scotland was of great service to the nation; the landholders borrowing notes and bringing the country into cultivation, and a spur being by that means given to various branches of manufactures. The Bank of Scotland continued to be the only bank in the country till the year 1727, when a new and similar establishment was constituted under the title of the Royal Bank of Scotland. These two establishments engrossed all the respectable banking business in the country till the year 1746, when a new association was formed, and incorporated by royal charter, with the title of the British Linen Company. The object of this association was at first to encourage the linen manufacture of Scotland, but gradually it fell into the course of common banking business, and now occupies a high station among these institutions. From £100,000, the capital of this bank has been raised to £500,000, where it has long remained stationary. By adroit management, it carries on an immense deal of business, and possesses as high credit as any bank in Scotland.

These are allowed to take precedence of others erected in the subsequent part of last, and in the present century, either in Edinburgh or in the provinces; and their shareholders enjoy the privilege of being responsible only for their individual stock.

All the banks, with few exceptions, are joint-stock associations, and are banks both of deposit and issue. Except the few private houses, all issue notes of one pound and upwards, which are payable on demand at the office whence they are issued. It was at one time ordained that Scottish bank-notes should not be re-issued after they were three years old; but such a regulation is abrogated, and they are now sent out as long as they are in good condition. Almost all the modern notes are produced from plates of hardened steel, and of such peculiar and intricate devices, that forgery cannot be attempted with success, or remain long undetected.

No periodical returns of their issues are made by the Scottish banks. But on turning to the evidence given before the parliamentary committees of 1826, we find the usual value of the small notes in circulation estimated by Mr Paul of the Commercial Bank, and Mr Blair of the British Linen Company, at £1,800,000, which is increased by a third at particular seasons, and when trade is brisk. The committee estimate the paper money of all kinds in circulation in 1826 at £3,309,082. But in the year of great speculation, 1825, they estimate the highest amount of notes in circulation at £4,683,000, the lowest at £3,434,000.

The following is a return of the joint-stock banks existing in Scotland at 5th January 1839, with the dates of their establishment:—

The Bank of Scotland, Edinburgh, 1695; the Royal Bank of Scotland, Edinburgh, 1727; the British Linen Company, Edinburgh, 1746; the Commercial Bank of Scotland, Edinburgh, 1810; the National Bank of Scotland, Edinburgh, 1825; the Aberdeen Bank, Aberdeen, 1825; the Ayr Bank, Ayr, 1825; the Dundee Banking Company, Dundee, 1825; the Dundee Union Bank, Dundee, 1825; the Dundee New Bank, Dundee, 1825; the Glasgow Bank Company, Glasgow, 1825; the Greenock Bank, Greenock, 1825; the Leith Bank, Leith, 1825; the Paisley Bank, Paisley, 1825; the Perth Banking Company, Perth, 1825; the Renfrewshire Banking Company, Greenock, 1825; the Paisley Union Bank, Paisley, 1809; the Aberdeen Town and County Bank, Aberdeen, 1825; the Arbroath Bank, Arbroath, 1825; the Dundee Commercial Bank, Dundee, 1825; the Glasgow Union Banking Company,

Glasgow, 1830; the Ayrshire Banking Company, Ayr, 1831; the Western Bank of Scotland, Glasgow, 1832; the Central Bank of Scotland, Perth, 1834; the North of Scotland Banking Company, Aberdeen, 1836; the Clydesdale Banking Company, Glasgow, 1837; the Southern Bank of Scotland, Dumfries, 1837; the Eastern Bank of Scotland, Dundee, 1838; Edinburgh and Leith Bank, Edinburgh, 1838: being 29 in all.

The business done by the Scottish banking-houses is prodigiously increased by the institution of their branches in the provincial and country towns. From those banks already noticed, which are situated in Edinburgh, and from two or three of the chief provincial banks, there were altogether deputed, not long since, about one hundred and forty branches, and this number is undergoing a regular increase. These subsidiary establishments are to be found in every town of any note, from the borders to the most northern point of Scotland. They are conducted by resident wealthy or responsible merchants and others, who give securities for intromissions, and are subjected to a very rigorous supervision by inspectors, who are continually travelling about for this purpose.

The prudent and enterprising manner in which the business of banking is conducted in Scotland, has often been the subject of remark and commendation. Several reasons may be assigned for the remarkable stability of the Scotch banks. Each bank, before gaining credit with its neighbours, must show that it possesses a sufficient paid-up capital, with a reserve fund in London, on which orders for balances may be given. It is also the custom of the banks to exchange the notes of each other once or twice a-week, by which means the notes are sent very speedily back to the issuers, and thus an over-issue on the part of any single establishment is prevented. There can only be an over-issue by all the banks in the country becoming equally reckless, a thing not likely to occur to any serious extent. A third cause of the stability of the institutions, is the liability of shareholders for the debts of the establishment. Excepting in the case of the three old-established banks above specified, all the shareholders in the various banks are liable not only for the amount of their own shares, but for the shares of all the others; and the whole of their property may be seized to make up deficiencies. Although many of the shareholders are certainly not men of opulence, a number are so; and as their fortunes are good for the paper issued, the public runs no risk of injury. To strengthen this liability of shareholders, by the law of Scotland all heritable property, lands and houses, may be seized in satisfaction for their debts. As this is not the case in England, where personal or moveable property can alone be taken by creditors, it would not be possible to establish banks in the south part of the island on the principle of the Scottish banks, till the law touching heritable property be altered.

Other causes, not of a legal nature, conspire to render the system of Scottish banking perfect. By reason of the circumscribed limits of Scotland, and the character of the people, a ramification of intelligence is created and preserved throughout the whole of society, altogether unknown in England, whereby the character, the wealthiness, and the conduct of the partners or directors of each bank, are made fully known to the rest. All seek, and all find, a knowledge of the management of each other. All are mutually on the watch; and symptoms of over-issues or other improprieties are spread with an amazing celerity, and have their immediate effect.

In comparing Scottish banking institutions with those in England, and considering the different manner in which paper money has been guided by the two nations, the uniform security of the former appears almost miraculous. From the first issue of the bank-notes in 1704, till the year 1830, a single panic or general run did not occur in Scotland, although, during at least two-thirds of the intervening period, paper money had been used to the almost total exclusion of a gold cur-

rency. Partial and very temporary runs have assuredly been felt, from the effects of short-lived slander or mistaken notions, which have invariably been readily quashed; but in the course of a hundred and twenty-six years, there have only been two or three cases of banks failing to pay twenty shillings-a-pound (they paid 10s.), and four, in which, after a short suspension of payments, all demands were liquidated. Their failure or stoppage, with the exceptions we mention, did not put the public to any loss; but this was to the injury of the shareholders, many of whom were reduced from affluence to poverty.

The very common practice of making deposits of small sums in the banks, has further assisted in giving strength to the institutions. Each bank receives deposits of any sum above L.10, for which a regular interest is given; and on this account the banks may be said to be the custodiers and traders upon all the spare capital of the country. Besides employing capital in discounting bills, lending money on heritable security, &c., the Scottish banks grant loans of fluctuating amount, called *cash accounts*. By a cash account is signified a process, whereby an individual, on entering into an arrangement with a bank, is entitled to draw out sums as required, to a stipulated amount, and by an implied condition to make deposits at his convenience towards the liquidation of the same.

Cash accounts are said to have originated from the following circumstance:—A shopkeeper in Edinburgh, in the year 1729, found himself at times in the possession of more than a sufficient supply of ready money to carry on his trade, the overplus of which he consigned to the care of the neighbouring bank. But on other occasions, by reason of the length of the credits given to his customers, his money became so scarce, that, after exhausting his bank deposits, he still felt himself in difficulties. Several dilemmas of this kind having occurred, he was prompted to make a proposal of a novel nature to the bank, to the effect that, if it would accommodate him in straits with small loans, he would always shortly afterwards make up such debits, and that the parties should come to a balancing of accounts at periodical intervals. It seems this proposal was acceded to. A cash credit, or liberty to draw to a certain extent, was instituted under securities; and thus originated a system which has been of immense benefit to bankers and traders, and is now followed over the whole of Scotland.

Cash credits are guaranteed by two sufficient securities, or the applicants give infirmity to heritable property in caution of the contingent debt, and when any such debt is liquidated, the deed is cancelled. The expense of expending a cash credit varies according to the amount of the desired loan. One for L.500 may be stated at about L.15. The deed requires no renewal. At the end of every six, and in some cases twelve months, calculations are made of entries and debits; the interest for and against the bank—the one being a per cent. higher than the other—is added and balanced, and an account being then rendered, the balance, if in favour of the bank, is either paid up, or remains against the debtor at interest to his new account. In these cash credits, the borrower is always at the mercy of the bank, which can call upon him at any time to balance his account, or, by his failing to do so, have recourse upon his securities.

Since 1729, cash credits have increased to an amazing extent. In 1826, it was computed that there were TEN THOUSAND in Scotland, varying in amount from L.100 to L.5000 each, but averaging from L.200 to L.500. Though originally designed for mercantile persons, they are now operated upon by farmers, manufacturers, house-builders, miners, lawyers, and all classes of traders and shopkeepers. From 1826, it is extremely probable that, instead of decreasing, they have increased a thousand or two more.

Banks are in the present day established in every civilised country. In the United States of North America they have been instituted to a great extent, and

frequently on most unsound principles, their notes being for very small sums, and these in few instances negotiable without a loss at a comparatively short distance from the place of issue; often, also, there has been an universal stoppage of cash payments, in consequence of over issues of paper money, a sure testimony that the country was trading beyond what its actual capital warranted.

Savings' Banks.—These are banks for receiving and taking charge of small sums, the savings of industry, and have been instituted for the benefit of workmen and others, who may be able to spare a shilling and upwards from their weekly earnings. The first savings' bank is understood to have been begun in Philadelphia in 1816, since which time they have been established in all parts of the United Kingdom, France, and other countries. Several acts of parliament were successively passed between 1817 and 1828, for the regulation of savings' banks in England; and in the year last mentioned, the whole of these were consolidated in one statute (9 Geo. IV. chap. 92). This act, together with another passed in 1833, conferring additional and important privileges on savings' banks (3 Will. IV. chap. 14), constitutes the existing law relative to these useful establishments: in 1835, the act was extended to Scotland. Savings' banks established according to the provisions of these acts are entitled National Security Savings' Banks, because the money deposited in them is paid into the Bank of England on account of government, whereby the nation becomes security for the amount of deposits—a security reckoned the best of all that could be given to depositors. The interest given by government on the sums so deposited is L.3, 16s. 0½d. per cent. per annum, whatever may be the fluctuations in the value of the public funds during the term of investment. This rate of interest being higher than what government could otherwise borrow money for, it happens that the public are really losing money annually by their generosity. The rate of interest payable to the depositors is L.3, 8s. 5½d. per cent. per annum.

Deposits of from *one shilling to thirty pounds* may be received by these banks; but no individual depositor is allowed to lodge more than thirty pounds in one year, or than L.150 in whole. Charitable and provident institutions may lodge funds to the amount of L.100 in a single year, or L.300 in all; and friendly societies are permitted to deposit the whole of their funds, whatever may be their amount. Compound interest is given on the sums lodged, the interest being added to the principal at the end of each year in some banks, and at the end of each half-year in others, and interest afterwards allowed on the whole. Any depositor may receive, on demand, the money lodged by him, if it do not amount to a considerable sum; and even in that case it will be returned on a few days', or at most two or three weeks' notice. Practically, payment is always made on demand. The wisest and most effectual provisions are made for ensuring the proper management of the affairs of the banks, so that those who intrust them with their money may place implicit reliance on its safety.

Each depositor is provided with a small book, in which his deposits are entered, and the amount of his interest marked. On the 20th of November, the interest is added in the bank books whether the depositor call or not. It is computed for the full term, and upon every fifth fraction of a pound. Depositors have thus the advantage of having their principal sum gradually increasing at 3½ per cent. compound interest. So successful has been the establishment of the savings' banks in England, that in November 1835 there had been deposited in them up till that period, the sum of sixteen millions and a half of pounds. The deposits now amount to about twenty-two millions.

HISTORY AND NATURE OF LAWS.

THE ROMAN LAW, AND THE SYSTEMS DERIVED FROM IT.

LAW may be defined as a system of regulations adopted in social communities for the general advantage, and on that account binding upon all the individuals constituting the community. Such regulations being absolutely essential to the existence of a social state, we may safely infer, that no sooner were any portion of mankind advanced into that state, than law began to exist. Its origin, being thus early, is necessarily obscure: we know extremely little of its history in any of the nations of antiquity besides Greece and Rome.

In Grecian history, we find more than one well-known code of laws; but so limited and simple was their operation, and so little are they adapted to the wants of a complicated state of society, that they are to be looked upon rather as the municipal regulations for the temporary government of a small knot of men, than as systems from which any additional hints are to be obtained to aid modern jurisprudence. It does not appear to have been in Greece—the source, as it was, of philosophy, literature, and art—that useful laws, applicable to the business of life, had their origin. The Phœnicians, of whose history and institutions we unfortunately know so little, seem to have been among the first to establish a general system of mercantile law, which their extensive commerce distributed abroad. To Rhodes, which can scarcely be considered a province of Greece, we owe the earliest regulations applicable to shipping. The law of average, or that by which the loss occasioned by throwing goods overboard to relieve a ship in distress is laid proportionally on the whole property saved (a most important branch of the commercial code of modern nations), had its origin in that state, and is still called the Rhodian law.

There is the less importance in the inquiry into the laws of early nations, since all of ancient law which continues to have any force in civilised Europe, has come to us through one channel—namely, the Roman law. Most European nations, being, as it were, the remoulded wrecks of the Roman empire, have obtained the basis of their laws from that source. The Roman law is, therefore, by the common consent of Europe, denominated *The Civil Law*. In Europe, there was but one other system, at an early period, to combine with it. This was *The Feudal Law*, or that code of usages which had sprung up in European nations before they received the civil law. It is, after all, only in some countries that the feudal law exists: in other cases, the civil law has established a proportionate, and in some a preponderating influence. In Holland and Germany, the original purity of the principles of the civil law have been preserved with such zealous care, that the writings of the lawyers of those countries are quoted as authorities on the law of Rome. In Spain, the system has been grafted on the feudal law, and on some peculiar customs derived

from the Moors. In France, previously to the Revolution, the civil and the feudal law were united, as in most other nations of Europe; and in the Code Napoleon, which we shall hereafter have more particularly to notice, there are many regulations from the jurisprudence of Rome allowed to exist, or revived, while many of the feudal customs which were formerly so prominent are abolished. England distinguished herself from the other nations of Europe by rejecting the civil law as authority, but many of her institutions were derived from its spirit and practice. "With all its imperfections," says Sir William Jones, "it is a most valuable mine of judicial knowledge; it gives law at this hour to the greatest part of Europe, and, though few English lawyers dare make such an acknowledgment, it is the true source of nearly all our English laws that are not of a feudal origin." In Scotland, the Roman law has always been a special subject of study; and though the number of native decisions, the extent of statute-law, and the necessary adaptation of the system to a state of society very different from that in which Justinian promulgated his laws, have rendered references to this source comparatively unfrequent, the civil law is still authority where the particular law of Scotland does not contradict it. It is a special object of study by the legal profession, and is the subject on which the members of the bar are first examined before they are admitted to practice. To complete the general outline of the influence of this system in modern Europe, it must be mentioned as the source of the canon law, which was created into a system by the Church of Rome, and still exists more or less, either separately or incorporated with other systems, in all countries where the papal authority was acknowledged. The law of nations, or international code, has been, by the common assent of civilised nations, derived from the law of Rome.

Writers have divided the legislative sources from which the laws of Rome spring into five. Among the first of these is generally classed the people, and the laws sanctioned by them are technically divided into the *Lex* or *Populiscitum*, and the *Plebiscitum*, the former including the acts of the whole people, the latter those of the plebeians convened by their tribunes. It would appear that, in the earlier periods of the monarchy, the authority of all classes was in this description of legislation tolerably equal. Servius Tullius, however, the sixth king, introduced the well-known divisions into centuries and classes, by which ninety-eight votes were secured to the first class, while ninety-five only were allotted to the remaining five, of which the lowest and most numerous possessed only one. The tribunes, who were officers chosen for the ostensible purpose of protecting the people from the tyranny of the aristocracy, were, by the exclusive and important power they possessed, again the means of restoring popular election.

They procured the assembling of the people by tribes, in which their votes were given individually, and without the necessity of a property qualification. All popular legislation, however, soon disappeared with the authority of the emperors. Augustus, except in one instance, found the popular assemblies profoundly obedient, and under his successor they ceased to exist; so that long before the Roman laws had become the grand system of jurisprudence which they constituted under the auspices of Justinian, the popular source of legislation had been dried up.

The decrees of the senate (*Senatus consulta*), are another source of the Roman law. The legislative power of this body seems to have grown out of its judicial, which was at first its proper province. By the original constitution, the people alone were understood to be the makers of the laws, and their authority seems to have been gradually engrossed by the senate, the interference of which, from having been confined to mere advice and paternal assistance in legislation, gradually extended itself to that of making laws. It was not till the days of Tiberius that these decrees were publicly promulgated as laws; but the senate had by that time lost its independent authority, and become merely an instrument in the hands of the emperor. The proceedings of the senate were generally suggested by some public officer, as a minister of the crown now introduces a bill into parliament, and a majority decided for passing or rejecting. In later times it became the practice for the emperor to propose a new law either by a message or letter laid before the senate, or by an oration delivered; and as there was no opposition intended or permitted, the legislative body became the mere registrars of the monarch's will.

Another source of the civil law is the constitutions and rescripts of the emperors. At what time they commenced the practice of making laws without the nominal concurrence either of the senate or the people, is not very distinctly known. A passage in the Pandects, the authenticity of which, long doubted, has been confirmed by late discoveries, states that the will of the emperor is law, and that by a particular act, the people had conferred upon him all their own power, which was thenceforth absolutely to remain in his hands—one of those transactions under the guise of which rulers are so fond of concealing their lust of power, by representing as a free gift that which no one can venture to refuse. Hadrian is believed to be the first emperor who exercised the authority of a supreme legislator. The imperial laws were issued in a variety of forms. Sometimes there was a new constitution springing from the monarch's own creative mind—on another occasion he would give his imperial judgment on some nice speculative question of law dutifully submitted to his wisdom. Many of the imperial laws, however, were the decisions of the monarch in particular cases, the spirit of which was piously preserved by the lawyers of the age, as the best criterion for a general rule of action. In modern times we associate with despotism a horror of innovation, and a desire to leave all institutions, whether expedient or hurtful, untouched. It was different in imperial Rome. The emperors were never tired of displaying the legislative produce of their own genius, or those which the prudent and courteous discoverers did not compete with them for the merit of suggesting. During four centuries, from Hadrian to Justinian, the manufacturing of legislation was in almost constant operation. Diocletian alone enacted 1200 new laws—a number that would do no discredit to a moderately long reign of a British monarch.

Edicts of the prætors are another, and not the least important, source of Roman jurisprudence. Of these high magistrates there were different numbers at different times; but the supreme authority vested in two, one having jurisdiction over the city, the other over the provinces. The prætor held his office for a year; and, as a provision against his adapting his judgments to his own personal views, the Cornelian Law obliged him to issue a sort of proclamation at the commencement

of his magistracy, embodying the general principles to which he should adhere in his judgments; and thus, at the moment when he was least acquainted with the duties of his office, he had to fix the plan on which he was to execute them. The prætor was not originally vested with legislative power—it arose in the exercise of his judicial authority. He was merely the interpreter of the laws; but when they seemed to him to be hard or otherwise erroneous, he did not scruple to suspend or alter their execution. The prætorian law has been compared to the equity system in England—a distinct system of law, arising out of those instances in which it was necessary to give relief from the strict interpretation of the common law. The common law had fixed a particular rule; a case would arise in which its application would be very oppressive: the common law judges, bound by their system, could give no relief; but the chancellor took upon him to modify the evil, and his decision was followed in like cases. The system of the prætors was somewhat similar, with this difference, that as they had no judges to compete with who pursued a system of strict interpretation, their equity had rather a tendency to modify the common law than to raise a rival structure. "The secret or probable wish of the dead," says Gibbon, when illustrating the prætorian system, "was suffered to prevail over the order of succession and the forms of testaments; and the claimant, who was excluded in the character of heir, accepted with equal pleasure from an indulgent prætor the possession of the goods of his late kinsman or benefactor. In the redress of private wrongs, compensations and fines were substituted to the obsolete rigour of the Twelve Tables; time and space were annihilated by fanciful suppositions; and the plea of youth, or fraud, or violence, annulled the obligation or excused the performance of an inconvenient contract." With the expiry of his year of office, the edicts of the prætor ceased to be imperative; but they were still looked up to as precedents; and when they became venerable by long use, they were considered as part of the fixed law of the land. By an enactment of the Emperor Hadrian, called the "Perpetual Edict," this doubtful and fluctuating branch of the law—at least as much of it as the emperor chose to sanction—received what might be called the royal assent, and was incorporated with the other portions of the civil law, as a distinct branch of the system.

In almost every nation which has passed gradually from barbarism to civilisation, many laws will be found to have come into existence without the direct interference of any legislature, and from no better defined origin than a habit on the part of the people of submitting to certain rules, or obeying the commands of certain individuals: it is, indeed, generally in this manner that legislatures have originated. A considerable portion of the Roman law was of this kind: it arose in custom, was handed down by tradition and practice, and called consuetudinary law. It is a disputed question, how far it was necessary that some competent authority should certify that the principle actually was an established portion of the ancient customs of the nation, before it could be safely acted upon as law. It is a peculiarity of the civil, as distinguished from the English jurisprudence, that, according to the former, a law may be tacitly abrogated by long disuse. In England, no law, however long forgotten, ceases to exist till it be repealed by the legislature.

The last fountain of Roman jurisprudence which we shall notice, is the *Responsa Prudentum*—literally, the answers of the wise men—the opinions of the sages of the law. It is difficult to conceive a state of society in which the opinions of legal writers, as to the interpretation of the law, will not have an influence. If a case occur in which the judge is uncertain as to the proper application of some enactment, where can he find a more suitable or a safer guide than in the opinion of some far-seeing lawyer, who has anticipated the case without knowing the parties, and who, consequently, cannot have proceeded on a bias to one or the other—a defect

of which the judge, if he be the first to interpret the law, will be at least suspected? Even in England, where interference with the doctrines of the common law is so jealously opposed, the early commentators are the only authority for its provisions; and there is no doubt that they gave the hue of their own opinions to the doctrines they laid down. In Rome, however, where the profession of the law, instead of being a trade, conferred a high rank in society, the opinions of leading counsel had a much more extensive range. They not only interpreted, but they could create law, by suggesting how the decisions should proceed in imaginary cases. At an early period, the relation of lawyer and client was that of patron and dependant. Patricians alone could act as lawyers, and the science was involved in riddles to which they only possessed the key. The poor client was dependent on the good will of his lordly patron for such protection from oppression, whether through the law or otherwise, as the influence of the latter might enable him to afford. When population and transactions increased, and the laws, instead of a mystery, became a serious study, which depended more on laborious application than simple initiation, the profession was opened to plebeians. It became not an unusual case, at a still more advanced period, for the patron and lawyer to be separated; the former being chosen for his influence, the latter for his skill. The forms which regulated the intercourse between patron and client, however, still retained some relics of their origin; and it is a striking illustration of the influence which Roman jurisprudence has exercised over the human race, to find these still existing. To this day, it is against all etiquette to bargain with a barrister for his work. The law gives him no claim for remuneration, which it kindly views as unworthy of the dignity of his profession; and it is usual to pay him beforehand for his legal assistance. On the other hand, though he has been paid beforehand, he cannot be compelled to perform any duty in return, for he is presumed to assist the client from his own free good will. In most other professions, it is the custom for the person employed to feel under a sort of obligation to the employer who has preferred him to others. This principle is reversed at the bar; for the person employed is the patron, and the employer the client.

But to return to the legislation of the sages of the law. During the commonwealth, whoever, by his superior sagacity or knowledge, could obtain deference for his opinions, might be said to be a manufacturer of laws. Under the earlier emperors, the privilege of promulgating authoritative opinions was confined to a limited number of lawyers, of equestrian rank, licensed by the government; but the profession was again thrown open to the public by Hadrian. The most brilliant era of legal wisdom commences within a short period of the decline of the republic, and terminates with the reign of Alexander Severus. Mucius Scaevola, the tutor of Cicero, was one of its earliest ornaments; and it included the celebrated juriconsults Paul, Ulpian, Papinian, Capito, and Labeo. The two last of these, who lived in the age of Augustus, were the founders of the two sects—the Proculians and Sabinians—into which the Roman lawyers were divided. The former advocated the doctrine that the laws should be amended at discretion, to meet circumstances as they occurred; the latter maintained the theory of their strict interpretation, be its inexpediency in the particular instance what it may. Capito, applying his doctrines to the inroads which the emperors were gradually making in the freedom of the republic, was a supporter of this species of innovation, and his followers were enrolled among the ready tools of despotism. Labeo sought to support the ancient freedom of the republic by an adherence to the letter of the old laws, and his sect became the champions of what may be termed constitutional freedom. The conflict is not unlike that which lately existed in Britain between Lord Mansfield and Lord Camden; the former supporting, to a certain

degree, an equitable, the latter, in all cases, a strict interpretation of the law.

Having now enumerated the principal sources of the Roman law, we may notice its remarkable epochs. The laws enacted during the reigns of the kings, although a curious subject of inquiry among antiquaries, exercised too little influence on the civil law, as handed down to modern Europe, to be of much practical importance. During the administration of the decemvirs, the celebrated laws of the Twelve Tables were adopted. The traditionary history connected with this code is, that the Roman government, conscious of the want of a proper legal system, sent commissioners to Greece, who, after studying the laws of that comparatively civilised nation, produced the Twelve Tables for the acceptance of the Romans. The tradition, like many others connected with the Roman history of the period, has not sufficient historical evidence to support it against its natural improbability. These laws, of which specimens are professed to be preserved, are written in a language so different from that of the classical writers of Rome, that they were to Cicero an object of much the same curiosity as the old Scottish acts were to Bacon. Like the first laws of other rude states, they are simple and brief in their enactments. The bankruptcy system, which has so sadly shocked several benevolent scholars, that they have endeavoured to explain it as a merely symbolical provision, is peculiarly sharp and effective. It enacts that the insolvent debtor shall be cut in pieces, and that his body shall be distributed among his creditors. When law became a science openly studied, the Twelve Tables became the subject of many commentaries. It was not, however, till the Romans had been for some time degenerating, that those great collections of legislative wisdom which have come down to modern times were commenced. The first attempt to construct a code, seems to have been the Perpetual Edict of Hadrian, already alluded to. Two private individuals, Gregorius and Hermogenes, appear to have collected the imperial constitutions into a system, or code, of which some fragments are still preserved. Nothing whatever is known of the biography of these compilers: it has not even been discovered in what reigns they respectively lived, though their labours received high commendation at the hands of Theodosius the Younger. Under this emperor, the celebrated Theodosian Code was promulgated, in the year 438. The compilation of this body of laws was committed to eight individuals, who were allowed considerable latitude in explaining and abridging, and even in supplying deficiencies. It contains the legislative acts of sixteen emperors, from the year 312 to 438. Fragments of this code have been rescued from oblivion inch by inch, by modern scholars, whose labours, it may safely be calculated, have amounted to some twenty or thirty times more than those of the original compilers. The celebrated Godefroy of Geneva spent thirty years in the task; and within the last twenty years, the discovery of some further fragments induced the celebrated Angelo Mai to study the Roman law for the purpose of editing them.

It is now our turn to notice those great collections of the legal wisdom of the Romans, to which the above may be considered only preparatory. In 529, ten commissioners, appointed by Justinian, prepared *The Code*, or *Codez*, as it is termed, from the collections previously made, and the intermediate enactments. Soon after its promulgation, the emperor issued several new constitutions, and the whole were consolidated and re-issued in 534. This great task was superintended by the celebrated Tribonian, whose eminent learning and discrimination, allied with untiring industry, but stained by the vices of corruption and partiality, have afforded a fruitful theme of praise and obloquy. This was by no means Tribonian's only labour. In the year 530, he was appointed the chief of a commission of sixteen, whose duty it was to cull the choice and useful passages from the authors of comments and opinions. The various authorities, which, we are told, would have made several camels' loads, were thus reduced within

a compass which, if it do look somewhat formidable to the consulter, is still manageable. Such are the fifty books which constitute the celebrated "Pandects," or "Digest" of the Roman law; a work without which modern Europe would have known but little of the subject. Along with Theophilus and Dorotheus, the indefatigable commissioner was able to prepare, in conjunction with this great digest of the law, an abridgment or manual of its leading principles, which bears the well-known name of "The Institute." This condensed and elegant little work was sanctioned by the emperor in 533. It has become the subject of innumerable comments, and has afforded the model on which the legal writers of most modern nations have desired to prepare their treatises. Justinian continued, during the remainder of his life, to promulgate new laws; and these, collected together under the title of "*Novellæ*," or "Novels," form the remaining department of the "*corpus juris*," or body of the civil law.

With Justinian we reach the climax of the Roman law; and to trace its farther progress in the empire has been more a subject of curiosity to the antiquary than of importance to the lawyer. Some fragments by later commentators, chiefly in the Greek language, have been disintombd by zealous searchers. The Roman law was nominally respected by the northern conquerors of Rome. Alaric, King of the Visigoths, indeed, caused a compendium to be prepared for the use of his dominions, consisting chiefly of an abridgment of the codes of Gregorius, Hermogenes, and Theodosius. Towards the end of the ninth century, Basilus, Emperor of the East, issued a new code, intended to supersede the labours of Tribonian, termed the "*Basilica*."

In the dark ages, however much of the Roman law may have remained in practice, it had died away in literature, and was neither studied nor commented on. At the taking of Constantinople in the fifteenth century, only one copy of one of the Justinian labours, the *Novels*, seems to have been discovered. It was long believed, indeed, in the learned world, that from the period of the *Basilica* to the twelfth century, the very existence of the Roman law was among the things forgotten. The circumstances of its resuscitation were found in a traditional anecdote, that at the siege of Amalphi in 1137, some Pisan peasants discovered a complete copy of the Pandects among the plunder, the melodious language, comprehensive philosophy, and clear definitions of which, so charmed the readers of that barbarous age, that its contents were immediately devoured with avidity and propagated with zeal. In Florence, a manuscript is still preserved, said to be the identical book with which this anecdote is connected, taken at the siege of Pisa in 1406. The essence of the tradition has been disproved by late discoveries, which show that the civil law was known previously to the siege of Amalphi.

The real revival of the civil law is to be traced in the history of the universities. Of these, Paris, Bologna, and Leyden, took the lead in the department of jurisprudence. Contemporary with, or immediately after the siege of Amalphi, lectures were given on the Pandects in the University of Oxford, by a teacher of the name of Vacarius. For reasons which we shall have to state when we come to treat of the laws of England, the civil law, thus early commenced, never made much progress in England. Nor, although the civil law was so prominent a subject of professional study in Scotland, has that part of the empire done much to elucidate the science. Both England and Scotland, indeed, have produced writers on the civil law; but with one or two exceptions, the British jurists are not among those names which become familiar to the readers on the subject, from the frequent reference made to them by subsequent commentators. The earlier modern civilians followed three oracles, Bartolus, Baldus, and Accursius, whose works, it is believed, the most enthusiastic admirer of the study would not now peruse, and who probably retain their chief celebrity from having been targets for the wit of Rabelais. In the seventeenth century, more elegant and philosophical commentators

followed, and the subject was pursued with zeal to the middle of the following century. A prodigious number of civil law books issued from the press during that period; and we have heard it asserted, that a complete collection of all the books published on the civil and canon law would make a library of two hundred thousand volumes. The labours of Godefroy alone are sufficient to make a modern literary collector shudder; and there is perhaps no surer mode of comprehending what human patience and perseverance is capable of, than the contemplation of a civil law library. Holland has been profuse with great authorities: Grotius, Matthæus, Schulting, Noodt, Voet, and Huber, belonged to that country. Germany produced the philosophic jurist Puffendorf, and Heineccius, whose elementary works, as the clearest and most methodical of the commentaries, have been popular as class-books of civil law. Among modern investigators in this science, the Germans have taken the lead.

To give a general outline of the Roman law, would be to describe the common principles of the majority of the codes of civilised mankind. Although the progress of commerce and manufactures has introduced a quantity of transactions—such, for instance, as bills of exchange—which the Roman lawgivers could never have contemplated, yet their system is the foundation of all the commercial laws of Europe, a circumstance which has probably facilitated the uniformity so necessary in transactions which involve inhabitants of different countries. From the same source, Scotland and the greater part of continental Europe have derived a marriage law so different from the ceremonious system that prevails in England. Its leading principle is, that the consent of the parties alone is necessary to a valid marriage, and that when that is proved, nothing more is necessary; and that a child born between parties who are subsequently married, becomes legitimate by that act. The law of trusts and of the mutual rights and obligations of guardian and ward, have found their way, more or less, into every modern system, and even into the statute-law of England. Prescription, or the principle that claims are limited by the lapse of time, has come down to us from the Romans. The law of testaments and the descent of moveable property, is mainly derived from the same quarter. It is in the case of the tenure and transmission of land, indeed, that the person versed in modern systems will find himself least at home in the Roman, from the effect which the feudal institutions of the various nations of Europe have produced on that branch of the law. The subjection in which children were placed to their parents is apt to create surprise, even when compared with the strict filial etiquette of our own ancestors. A revolting feature of the *corpus juris* is the portion of legislation devoted to the subject of slavery and the property in slaves.

The Roman law has already been mentioned as the source of the law of nations, or, as it is more justly called, the international law, in modern Europe. It was quite natural that a system voluntarily adopted among nations for regulating their mutual intercourse, should be founded, to as great an extent as might be expedient, on the system of the internal laws which the majority of the nations had chosen to adopt. But the law of nations is perpetually varying with circumstances, and it is impossible to draw that distinct view of its nature and provisions which may be given of the laws of any particular state. It has been argued, indeed, that the term "law" is improperly applied to the system. Wherever the term law is used, there is understood not only a regulation laid down, but a means of enforcing it in the hands of a superior power. The civil and criminal laws are enforced by the ordinary courts; the military law, by courts martial; the law of the church, by the ecclesiastical courts, &c. But who, it is said, is to be the judge to enforce the law between nations? When two nations have a dispute, and their power is equal, it remains undecided; if the one is much superior in strength to the other, it has matters its own way. In

the late war, Great Britain maintained that she had a right to search all neutral vessels, for the purpose of ascertaining if they contained contraband goods or sheltered deserters. The smaller states were bound to submit; but America resisted, and the dispute occasioned a bloody war. So it probably will be again, when the same claim is urged. Instead of being a fixed law applicable to all, the weak will have to obey, and the strong will resist. For the enforcement of any rules that may be called the law of nations, then, it is clear that there is no better sanction than this, that the powers which openly outrage them will call forth a degree of indignation on the part of the rest of the world which may prove dangerous. The partition of Poland, for instance, called forth the indignation of the rest of Europe; and it may be still a question whether the acquisition was a prudent one to the nations concerned. It is not to be supposed, however, that there are no courts where the law of nations is enforced. Each country in Europe has generally a court where its own views on the subject are laid down. England has, for instance, the prize jurisdiction of the Court of Admiralty, which is thus called a civil law court. During the late war, when Napoleon by his Berlin decrees declared Great Britain and her colonies in a state of blockade, and Britain retaliated by the orders in council on the rest of Europe, a multitude of cases where the ships of neutral powers had been seized for breach of neutrality were adjudged. And here a circumstance occurred which could not take place probably in any other country, that the view taken of the law of nations by the judge was different from that taken by his government; for Lord Stowell declared that a blockade could not be held to exist by mere proclamation, but that there must be present on the spot an armament sufficient to enforce it.

One of the principal defects of the writings in the civil law, and one that renders the subject in a great measure unpopular at the present day, is the spirit of speculation with which they are imbued, and the extent to which they carry divisions and arrangements which are of no service in practice, and provide for wants purely hypothetical. The civilian in his study, shut out from the world and ignorant of its pursuits, set his brain at work to create the various exigencies of practical life to which the maxims of the institute were applicable, and to devise how they could be applied; but when his labours were brought to the light of day, it was found that the world in its practice and he in his thoughts had taken totally different routes, and that the one could not be the companion of the other. If a tailor make clothes with another man's cloth, to which of the two shall they belong? If an artist paint on another man's canvass, who shall be the proprietor of the picture? Such were among the subtleties discussed among the Roman jurists. In later days, when legislators have too much to do in keeping up with the practical demands of society to indulge in hypothetical law making, such subjects would not be taken up until cases of difficulty actually occurred; and then, before deciding the abstract questions, it would probably be asked under what circumstances tailors are likely to make garments out of cloth which does not belong to them, or artists to paint on other people's canvass?

THE CANON LAW.

The Canon Law is, properly speaking, the ecclesiastical law of the Roman Catholic Church. In its more limited acceptation, it may be called the by-laws of the church as a separate corporation; but its field widened with the influence of the hierarchy. It embraced many subjects of purely civil and municipal law, such as the distribution of property between married persons, succession, &c., by linking them with ecclesiastical matters; and thus the clerical tribunals came to rival, if not to excel in importance, those of the state. The canons of the Greek Church, a portion of which were said to be the work of the apostles, added to and explained by general councils, were sanctioned by the Novels of Jus-

tinian, and have so been viewed as a portion of the body of civil law. A collection of canons was made in the year 520; and this work, with the papal decrees, and the privileges conceded to the church by Charlemagne, formed the chief subject-matter of the canon law down to the twelfth century. It was then that this law ceased to be the mere regulations of a peculiar body, and became a general system of jurisprudence. About the year 1114, a collection of the decrees of popes and cardinals was commenced by Ivo, Bishop of Chartres, and was revised and completed in 1149 by Gratian, a Benedictine monk. Another element in the system consisted of the Decretals, which were rescripts or epistles by the pope, or by the pope and cardinals, deciding how the law of the church stood concerning disputed matters referred to them. These were first collected and edited in 1234 by Raimond de Renafort, chaplain to Gregory IX. This work was divided into five books, to which a sixth was added under the auspices of Boniface VIII. in 1298. These two great works, with some additions made to them by succeeding popes, formed what, in imitation of the collected works in the law of Rome, was called the *Corpus Juris Canonici*, or Body of the Canon Law. Besides these general statutes, there were local canon laws passed by the clergy of various countries, at national or provincial assemblies, held under the auspices of papal legates or archbishops. In the reign of Henry III. there were assemblies of the former kind; and under the respective archbishops of England, there were frequent provincial synods. In Scotland, two provincial synods, held at Perth in 1242 and 1269, passed some important laws regarding tithes.

The great aim of ecclesiastical legislation was to bring civil questions within its pale. Disputes as to tithe and the privileges of the clergy came very naturally to its hand. The priesthood were in a great measure intrusted with the administration of legacies, especially where they were destined to pious uses; and they thus acquired a jurisdiction in questions of succession, of which we see vestiges in this country, in the Court of Arches and the other ecclesiastical courts of England, and the commissary system in Scotland. Marriage being constituted a sacrament, the canon law not only took into its hands all questions regarding the union and separation of the parties, but adjudged in the criminal act out of which the latter circumstance might arise, and took under its cognisance questions as to dower. The church obtained a powerful hold over the proceedings of ordinary courts of law, by the introduction of the practice of witnesses and parties calling God to attest the truth of their statements—the origin of the present system of administering an oath. Over this ceremony, and all matters connected with the truth or falsehood of the statement it sanctioned, the clergy took a particular charge. Notaries, who in the days of ignorance were intrusted with the execution and registration of contracts—who, in fact, were the living registers of almost all transactions of importance, were necessarily taken from the only class who could write—the churchmen, and their appointment and removal naturally fell into ecclesiastical hands.

A great rivalry thus existed between the civil and the canon law; but it was a friendly rivalry. The clergy were the repositories of both systems, and they had to decide how much should be assigned to the one and how much to the other. The canon law borrowed largely from the civil, of which it is sometimes considered a mere branch; it was naturally, indeed, the object of the clergy not so much to change the law itself, as to take the administration of it into their own hands. To be *juris utriusque doctor*, or doctor of either law, civil and canon, was a common distinction. During Henry VIII.'s reign, lectures on the canon law were abolished in England, and with them the corresponding degree. Jealous as the English were of the encroachments of the civil law, they still more determinedly opposed that of the canon. What the powerful court of Rome had set its heart upon, however,

could not be wholly resisted; but it was always a principle, that though the civil authorities of England might take laws from the ecclesiastical system, the canon law was never, in its own simple authority, to be obeyed within the realm.

THE FEUDAL LAW.

The feudal system and the Roman law may be said to have struggled for supremacy through nearly the whole of modern Europe. Of the influence of the latter we have already taken a cursory view. The former was an ingredient in the constitution of the continental and British monarchies. It was the source of those popular or aristocratic assemblies, which shared more or less, according to circumstances, the government of the various states in which they existed; and it was thus the ostensible origin of the British parliament. Trial by jury has been traced to a similar source. The constitution of the German empire is essentially feudal, and the customs, or peculiar local laws of the various provinces of France, previously to the revolution, were models from which the system was studied. The English law, especially that of real or landed property, is full of feudal usages, though their operation has often been checked. In Scotland, the forms of the feudal system may be found existing in almost original purity, though, as we shall hereafter see, they have been adapted, perhaps as far as they are capable of being so, to the wants of civilised times.

An account of the rise and progress of the Roman law must, for obvious reasons, be far more satisfactory than any that can be given of the feudal system. The former was (at least the greater part of it) the construction of ingenious individuals, possessed of authority to enforce their mandates on their fellow-beings. The latter gradually rose out of circumstances, and the state of society. It was not devised by a powerful legislator, to be promulgated to a willing people; but it rose out of habits and events which took place in an age when there were no historians to record their progress. Hence, the origin of the feudal system has been a fruitful subject of debate and theory; and in the absence of facts, it has often been necessary to resort to moral deductions. It has been maintained by some, that nothing can be more simple than the feudal system; that it was a mere arrangement by which military service was given in exchange for land, and that many half-civilised nations present instances of a similar contract. Ingenious speculators have found the resemblance of the system in particular stages of the history of Greece and Rome, in Turkey, Persia, Hindostan, and the Highlands of Scotland, among the aborigines of North America, and in the Loo-choo Islands. But, however important may be the investigation of such analogies between the practice of mankind under different circumstances, as a part of the history of the human mind, they throw but little light on the feudal system, the chief interest of which is to be found in the vastness of the field which it covered, and the influence which it has exercised for so many centuries over the legal institutions of Europe.

Since we can only say that this system existed, and cannot tell, as we have done in the case of the Roman law, the precise hands from which it came, it may be better to commence with some account of its leading principles, reserving for after detail a history of its progress. The essential elements of the system were land, and military service given for the use of it, by the vassal who held it, to the superior of whom it was held. It would be wrong to speak of either of these two parties as the absolute proprietor of the lands; for, in the more perfect stage of the system, each had his own peculiar privileges, with which the other had no right to interfere, except where the law permitted him. The vassal was not, in the general case, the slave of the superior. The duties and services he had to perform were regulated by compact or custom. On the other hand, however, he was not the independent proprietor of the lands he held. He could not convey

them to a purchaser, nor could he pledge or bequeath them, without obtaining the sanction of the superior to the person to be substituted to him. Land was thus completely removed from the operation of commerce; and in those countries where the feudal system continued to exist, it was only by fictions and connivances—by bribing the superior, or getting the courts of law to compel him to give his consent—that sales and pledges could be effected. The lands held in this manner were termed *fiefs*. When they became hereditary, as they did apparently by custom, arising from the tacit consent of the parties interested, the superior was still presumed to give an assent to the change from father to son; and before he acknowledged the latter as his vassal, he exacted from him a fine. When the successor was a minor, and thence unable to fulfil the military duties of the fief, the superior in some cases became his guardian, drawing the rents of the estate, and compelling him to marry whom he should point out, under a penalty, which, it would seem, ought to amount to the sum which the guardian, or superior, could receive by selling the alliance. The superior's claim upon the estate during the vassal's minority, became, like most other feudal exactions, fixed by usage, and seems in general to have amounted to one year's rent of the land. In some countries, females could not succeed. In others, where their right was acknowledged, the superior claimed the privilege of assigning husbands to them; and exacted a fine, sometimes as the price for permitting him to marry his ward. The feudal system, like every other, had its degrees of goodness and badness. Where we find the milder features of the feudal law, the right of the lord over his female vassals, or the wives and children of his followers, was a mere tax; but where the darker influences of the system were at work, it gave legality to a licentious despotism, which is frequently adduced as a disgusting memorial of the barbarism of fendality. Of illustrations of despotism, indeed, the feudal system is full. Independently of its own peculiarities, it would have been impossible for any legal system to have passed through the scenes of rapine, blood, and barbarism which characterised the middle ages of Europe, without being the instrument of many iniquities. At the outbreak of the French revolution, which at first was little more than an attack on the most offensive relics of feudalism in France, some of these horrors were dragged from their dingy retreat in parchment records and black-letter chronicles, to add to the frenzy of the times. Among other instances, was adduced that of a feudal lord, on his return from the chase in winter, disembowelling a vassal, that he might keep his feet warm in the reeking trunk during the evening revel.

The proper return of the vassal for his lands and the protection of his lord, was, as already stated, military service. Where this system was established as a fixed law, the quantity of service to be so given was regulated. A knight's fee imposed on the holder the duty of being forty days in the field for his superior, and the half or quarter of a knight's fee involved corresponding proportions of service. When fiefs came first into existence, it is probable that there was no other service worth possessing but the use of the strong arm. Conquered land was what the chief possessed, men to fight more battles was what he wanted; so that the one became the price of the other. It was not always the case, however, that land was valuable for nothing but as the reward of fighting, and it was gradually bestowed for other considerations; yet so closely connected had the relation of a military tenure become with land, that any other method of disposal was considered as irregular, and merely exceptional. Hence, when land was given without a price, and for the understood return of military service, it was said to be a proper fee; when any other consideration, such as a sum of money, was stipulated for, it was said to be improper. The former was always presumed to be the condition on which land was given, the latter required to be specially proved, and the un-

willingness to admit it called for those legal subtleties which have made the commerce in land, to this day, so complicated. It behoved that there should be possessors of land who were not of necessity soldiers, and it was necessary to the monarch, or feudal superior, to employ people in various other capacities. All, however, took the impression and stamp, as it were, of fiefs. Salaries, taxes, honours, and dignities, even board and lodging, were feued out; the person who had engaged to bestow them acted the part of superior, and he who received them that of vassal. The church enjoyed lands which were not exempt from the ordinary feudal services. In the earlier ages, churchmen in many cases themselves assumed the spear and buckler. When it was considered inconsistent for churchmen to fight, it was held as by no means unsuitable for the church to employ soldiers. A clerical establishment would sometimes appoint a patron, or chivalrous assistant, in the person of a neighbouring baron, who would be called the "advocate" of the establishment—the use, by the way, to which that word, which now designates a class of peaceful lawyers, was first applied. It is not unfrequent to find in old tenures that a particular monastery is to supply so many archers and spearmen for so many days.

Borough communities were another class to whom military service seems inapplicable, but who, nevertheless, almost universally held by that tenure. They obtained certain privileges, and in return they had generally to keep watch and ward in their respective towns; a service in which their own safety might not be less interested than the ambition of their lord. As the privileges conceded to these communities were large and important, they did not, in general, escape taxation along with their military duties; and in later times these exactions became generally commuted for a money payment. The privileges usually conceded to these commercial communities consisted of an exemption from the more vexatious of the feudal exactions, to be shortly noticed. These were generally conceded to them by the monarchs, as a counterpoise to the growing power of the feudal aristocracy; and within these sanctuaries commerce and civilisation created a power, by which both kings and nobility were effectually held in check.

Among those who were placed in the position of feudal vassals to the seignior, or lord, were his own domestic servants, whose power and influence would be, to a certain extent, measured by that of their master. To perform the menial duties of his household, a Roman emperor employed a slave, just as a senator or a pro-consul might do. The barbarian conquerors, however, gave lands to those who performed these functions; and the person who performed for Charlemagne the office of butler, valet, huntsman, or groom, got for his services the commodity most readily at his master's hands—portions of conquered territory. The services were thus performed as the consideration for feudal benefices. The menial servant of the monarch might have tenants and retainers under him; and thus the wages ennobled the functions. Hence we have had in modern Europe, masters of the robes, grooms of the stole, masters of the buckhounds, masters of the horse, &c., held by the highest nobility of the realm. The *graf*, or land-steward of a district, was an important personage. Instead of attending to the letting of paddocks, and the rotation of crops, he was intrusted with the power of life and death over the inhabitants. The humble grieve, who has the management of a small landed estate in Scotland, and the shire-reeve, or sheriff, who performs high judicial functions in the same part of the empire, have divided, as it were, between them the original duties of the feudal officer from whom their names are derived. The same feudal origin may be as distinctly traced, on a larger scale, in the relation of master and servant in modern times. Servitude, however menial, when allied with feudal dependence, did not carry the same degradation as mere slavery; and in the opinion of some, the situation of the feudal attendant was higher than that of the menial servant of modern days, who freely gives

his labour and attendance for a price. In Scotland, where feudal usages have lingered so long, it has been remarked, that the relation between master and servant is of a more confidential nature than it is found to be in other parts of the country. While the line drawn between their positions is as clear as it can well be in a free country, the situation of the servant has a more than ordinary share of respectability attached to it, because, instead of being the individual servant of an individual master, he and his race are looked upon, to a certain extent, as the retainers of the house which he serves. On this point, indeed, an adherence to feudal usages in situations to which they are not applicable, has been productive of one of the greatest evils of modern society—the extent to which servants are kept, not for use, but as an ornamental evidence of wealth. Our lineal aristocracy continue to follow, so far as the usages of the day permit, the practice of their ancestors; and the gentlemen of plush and shoulder-knots are the representatives of those who wore buff jerkins, and handled the pike. The rich merchant and manufacturer must not be without the usual insignia of wealth; and thus a race, whom idleness and constant association with each other must deprave, are kept up among a bustling and active community, as if we lived in the days when the majority must either serve or starve. It has been remarked, that in republics such as Holland, the wealth of rich individuals generally took the more ennobling direction of patronising the arts and literature.

In the earlier ages of the feudal system, when there was much land to distribute, the natural features and boundaries were sometimes little known to those who gave it away. The persons who received it were aggrandising and ambitious, and not likely to yield to each other disputed portions. Above all, the conquerors were uneducated, and had little means of giving perpetuity to their bounty by written deeds. From all these circumstances, the investiture of the vassal became a very important and solemn affair. Investiture was divided into proper and improper. By the former, the superior went in person to the land, assembled all his other vassals upon it, and showed them the portion he had assigned to his new follower. The vassal, upon this, did homage, accepting the grant, and promising to perform the usual services in return. By the improper investiture, of the full practice of which in our own day we shall give an instance, the superior gave authority to his bailiff, or some other person, to give investiture, which was done by the symbolical delivery of a portion of the property—some earth and a piece of stone generally—to the vassal, or some person authorised by him to accept the grant and perform his homage. Writing was probably in use before this latter usage was commenced, and the authority was generally a written one. The solemn investiture in presence of the co-vassals finally descended to a mummery between an attorney and his clerks. The necessity to have acts regarding the fiefs of a superior witnessed by his vassals, can be traced to a connexion with two of the most important institutions of modern times. The great vassals of a king, met together in public assembly to discuss what aids they might afford for their fiefs, how they were to defend them, &c., merged into a great council or legislature; and it is to such a body that the British Parliament at least partly owes its origin. At this moment, the Bishops of England sit in the House of Lords in virtue of the feudal baronies which they hold of the crown. Vassals of the lower grade were often summoned to attend at the hall of their lord as assessors, or assizers, to give, partly opinion, partly evidence, concerning some matter connected with the fief, or the conduct or rights of a fellow-vassal. With this institution, the system of trial by jury is intimately connected. A jury of perambulation, for the purpose of ascertaining boundaries—a sort of body lineally descended from the assemblage of co-vassals who were present at the investiture, and witnessed the extent of the gift—has been known in modern times.

It is probable, that if the feudal system had only established a relation between the monarch and his immediate vassals, the influence it would have exercised over the state of Europe would have been comparatively slight. The distribution of land as the reward of services, is frequently exemplified in history; but that which chiefly distinguished the feudal system, is the numerous grades of dependence, and the manner in which all parts of society, from the emperor to the lowest serf, were bound together in one system of lord and vassal. In the first place, there were various grades of vassals holding of the monarch. The majority of the lower classes, however, generally found themselves under the protection of some intermediate chief. The duke, or count, who held immediately of the crown, sub-feued to a dependant, who, on his part, might dispose of a fragment in a similar manner. By such an alienation, however, the vassal dared not in any way interfere with his superior's rights; the latter, indeed, was not presumed to be conscious of the sub-infeudation, unless he had specially sanctioned it, and by doing so, he acknowledged the sub-vassal as his own immediate retainer. When a vassal, therefore, sub-feued without his superior's consent, he gave only a portion of the estate he himself possessed, his sub-vassal being liable to meet all the exactions that might fall upon him. So, if he rebelled against his lord, or withheld the feudal exactions, the superior could seize upon the fief without reference to the claims of the sub-vassal. The highest feudal noble was the Heretoch, who, from the Latin *dux*, a leader, received the designation of duke: this class was intrusted with the administration of large provinces. The graf, who had a smaller charge, was called *comes*, or count; and one class of graf, who was intrusted with the marches, was called the *mar-grave*, *march-graf*, or marquis. These nobles generally held lands of their sovereign, while they were authorised to represent his person over the districts to which they were assigned, administering justice in his name, levying his feudal exactions on his vassals, and receiving their homage. These powerful feudatories were held in check by Charlemagne; but under his successors, and the other European monarchs, it became their aim to be the independent sovereigns of the territories committed to their charge—an object in which they were more or less successful according to circumstances, some throwing off their master's yoke, while others made themselves intermediate superiors between the king and his vassals. The various states of Italy and Germany are illustrations of the working of these events. The feudatories of France made a very near approach to independent sovereignties. They possessed within their own dominions the right of coining money, that of waging private war, exemption from all tributes, except the limited feudal duties by which they acknowledged the superiority of the crown, and finally, freedom from legislative and judicial control on the part of the sovereign and his courts. The vassal, too, in looking after his own concerns, sometimes conquered territories not inferior to those of his lord; and under such circumstances there was little chance of his being an obedient retainer. The Duke of Normandy, the vassal of the King of France, became monarch of England, and the Dukes of Burgundy were little less powerful.

From these high personages, vassalage went through many gradations till it reached abject slavery. There were the *vavassors* and *châtelains*, dependants on the higher nobility, but who themselves had large estates and fortified their houses. There were the burghers of free towns, whose privileges have been already mentioned. Of rank corresponding in the rural districts, were the *socage-holders*, and the class so well known in England by the designation *yeomen*. The lowest grade were the *villains* or *serfs*, to whom was committed the task of tilling the lands which the soldier gained or protected. It was the characteristic of the other grades of feudality to impose duties upon the lord, corresponding to those of the vassal, but the villen had little power to

exact performance of these regulations. There were grades, however, even among the serfs, though probably there were not instances in which one held of another as vassal and superior. The peculiarity of the class was, that they were astricted to the domain, and went with it when it changed hands. Some, however, had rights and privileges which they might maintain in the court of the manor of their lord. Some held small estates, which, however, they could not dispose of. The lowest class were as abject as the slaves of the Romans.

The different classes of feudal taxes have been mentioned above. There were others, however, of a more miscellaneous nature, which were chiefly encroachments on the purer spirit of feudality, dictated by despotism and cupidity. It was upon the vassals who approached nearest to the state of villenage that these innovations naturally fell most heavily. They were designated "aids," and were demanded by the lord on any occasion which caused him outlay. If he had to make war with a neighbour, or to portion off a relation in marriage, or to ransom a son, he demanded an aid. Aids were profusely exacted by the knights who joined in the crusades. In England, the aids that might be exacted, were restricted by *Magna Charta* to three; they were for the purpose of making the lord's eldest son a knight, for marrying his eldest daughter, and for redeeming his person from prison. By exactions in a different form, the more servile vassals were fleeced and kept in subjection. The superior, if he built a mill, astricted all his vassals to grind their grain at it, compelling them to pay a tax for the service they were forced to receive. He compelled them to assist in making roads and building bridges, and he exacted tolls of all below the degree of freeholders who crossed them—a system which placed impediments in the way of vassals escaping from place to place. He obtained tolls and duties, too, on the export and import of commodities; and if he found a clever artisan on his premises, he would keep him and his services for his own use.

The revival of literature was not favourable to pure feudalism. It brought with it the study of the civil and canon laws, and it was through the lights so acquired that the feudal customs were interpreted. The decline of the spirit of the feudal law is matter of history, and a view of it would lead to too long a digression. Not only its effects upon society, but its literal forms, still linger amongst us; even in republican America there is pride of birth, and a knowledge of the feudal system is sometimes requisite in ascertaining the title to property. Perhaps in no country has the letter of the feudal law been so curiously adjusted to the needs of modern society as in Scotland. As a general illustration of the system, we have drawn up from the notes of a professional friend the following outline of the manner in which land is conveyed and held in that part of Britain. All the land in Scotland is held of the crown, and the greater portion of it is possessed by vassals of the freeholders. Let us suppose one of these vassals selling a portion of his property, for a sum of money down, or an annual payment. There is only one side to the contract—that of the seller, for as he is going to act the part of a feudal lord giving away a benefice, it would be quite inconsistent for the buyer to come under any obligation to take the lands and pay for them. The seller, in a formal document, states, that he makes over the lands, and dictates what series of heirs they are to descend to, and how they are to be held. He then grants an authority to his bailiff to pass to the lands described, and invest the purchaser with them. The investiture is generally managed thus. A notary-public and four other persons repair to the grounds; one of these acts the part of the bailiff, or feudal officer of the seller, or superior; another that of the vassal's representative. The authority is read over, and then the bailiff, with all due solemnity, lifts a stone and a piece of earth, which he puts into the hands of the vassal's representative, who "takes instruments" in the hands of the notary by giving him a shilling, or protests that the ceremony is completed, calling on him (the notary)

to attest it. The other two parties are the witnesses. This makes the buyer the vassal of the seller; but it is generally preferable to be in exactly the same position in which the seller was. To accomplish this, the consent of the seller's superior must be had, and according to feudal usage, it is thus signified. In virtue of an authority, or "procuratory," a representative of the seller goes to the superior, or his representative, and by the symbol of a "staff and baton," as the law-books say, but practically of a pen, the lands are delivered into the hands of the superior, who transfers them over to the purchaser by handing the pen to him or his agent. Then follows an investiture by the superior in the above form, which is conducted in virtue of a charter granted by him to his new vassal. To the superior this is not entirely a barren ceremony, for he receives a year's rent of the property to reconcile him to the change of vassals.

THE LAW OF ENGLAND.

England has already been mentioned as an exception to the general prevalence in Europe of the civil and canon laws; not that these systems were totally repulsed, but that they met with a countervailing resistance, which prevented them from obtaining the influence they possessed in other countries. This resistance may be found in the existence of a different, and, it may perhaps be said, hostile system, called the common law, and to the power of parliament to make laws or statutes. The three great elements of the jurisprudence of England are the common law, the law of equity, and the statute law. To these may be added, as codes limited to particular spheres, the admiralty law and the ecclesiastical law.

Speaking of the common law, Sir Matthew Hale, its historian, says: "This is that law by which proceedings and determinations in the king's ordinary courts of justice are directed and guided. This directs the course of descents of lands, and the kinds, the natures, and the extents and qualifications of estates; therein, also, the manner, forms, ceremonies, and solemnities of transferring estates from one to another; the rules of settling, acquiring, and transferring of properties; the forms, solemnities, and obligations of contracts; the rules and directions for the exposition of wills, deeds, and acts of parliament; the process, proceedings, judgments, and executions of the king's ordinary courts of justice; the limits, bounds, and extent of courts, and their jurisdictions; the several kind of temporal offences and punishments at common law, and the manner of the application of the several kinds of punishments; and infinite more particulars, which extend themselves as large as the many exigencies in the distribution of the king's ordinary justice require."

Common Law.—The origin of this system, one of the most interesting subjects of modern investigation, is involved in deep obscurity. Its progress, subsequently to the reign of Edward I., who has been called the English Justinian, is pretty accurately noticed; but when an unprofessional inquirer reads those portions of English law-books which attempt to carry the history to an earlier period, he cannot help feeling disappointed at the unsatisfactory result. The more marked features of the system were, doubtless, the customs of the Anglo-Saxons. A collection of the laws of England during the heptarchy, or laws of the Anglo-Saxons, was published by an eminent antiquary, at the commencement of the eighteenth century; but there is great reason to believe that they were written some centuries after the Conquest, while the fragments of Anglo-Saxon legislation which they contain refer chiefly to the arrangement of the military force, the clergy, and other matters of general or police regulation, which, in the present instance, are less interesting than a little insight into the laws relating to private rights would be. Alfred and Edgar have acquired much fame for having collected and arranged the laws of their predecessors, reformed them where they were impolitic, and completed them where deficient; but it would be difficult to determine their exact merits.

Edward the Confessor enjoys a similar reputation. To him, indeed, history supplies us with good ground for referring equitable laws, for we find that when the people complained against the oppression of the Norman kings, they demanded "the good old laws of Edward the Confessor." It is probable, however, that the compliment did not apply to him so much in the capacity of a legislator as that of the last of the Saxon kings.

Whatever may have been the exact nature of the laws of the Anglo-Saxons, the Conquest effectually incorporated them with the feudal system, and the connexion between vassal and superior became one of the most important features of the common law. It is not to be supposed, however, that this was the earliest visit of feudal institutions to Britain. The Saxons could not well escape the influence of a system which had deeply rooted itself among the kindred nations of the continent; and many feudal institutions are to be found existing under the Saxon kings. The increase of the spirit of feudalism under the sway of William the Conqueror was, however, so great, that many authors have attributed its origin in England to the era of the Conquest. It was then, indeed, that it became oppressive. The conqueror brought with him the system of his own province, for which he was a vassal to the King of France, and could not admit the possession of landed property in England, except as held from himself in the capacity of lord paramount. The greater nobles—chiefly the conqueror's companions in arms—naturally held the lands he liberally bestowed on them of him as superior, and they compelled all who lived upon their lands, or even in their neighbourhood, to acknowledge them as liege lords. The forcible increase of such a system as the feudal law, could not but be attended with acts of great oppression. These were added to by the selfish magnificence of the princes, who cleared large tracts of country of inhabitants, that they might enjoy the regal pleasures of the chase in undisturbed tranquillity. The Saxons had their own county courts, but the greater part of the causes were, after the Conquest, removed from them to be pleaded in the court of the monarch, which attended on his own person. Legal proceedings were conducted in the Norman dialect of the French, which was afterwards changed into Latin. The use of a tongue unknown to the people at large, continued down to the days of Oliver Cromwell, and at the Restoration was restored, with other equally useful practices. It was abolished in as far as respects the proceedings of the courts in 1730.* If we knew nothing of the veneration with which the Saxons looked back upon "the good old laws of Edward the Confessor," the obstinacy with which they preserved their language would have led to the presumption that they had been equally tenacious of their ancient customs. The former outlived every attempt, moral, intellectual, or physical, by reprobation, sarcasm, or force, to extinguish it, and so, to a certain extent, did the latter. The judicial system, and the tenure of land, might both be altered; but to their original customs the people adhered so resolutely, that these were at length blended with the opinions and feelings of their Norman tyrants, and became to a certain extent the system of law which they administered. There was a further leaning on the part of the barons to the popular customs, from this circumstance, that the priests, whom they viewed as

* For many purposes connected with legal practice, Norman continued to be employed—law-books were written, and cases reported in it. The following specimen of a formal document of the end of the sixteenth century, gives a grotesque picture of the manner in which languages were twisted to suit the convenience of those who used them:—

"Fuit resolve per le pluispart de les justices et le counsell del Roigne, cest terme à Sergeants Inne, in presentia comitis Sussex Justic. Forestar citra Trentam, que le building dun novel Mease in le severall soyle on waste dascun home deins un Forest, est un purpresture et noynance al Forest et Game, et finable on arrentable, pour le tollation ou permission de ceo destruyre al arbitrement et discretion del justice, ou raceable et destrue al pleasure," &c.

dangerous rivals, attempted to introduce the doctrines of the civil and canon laws. Hence it was, that at the parliament of Merton in the thirteenth century, when an attempt was made to legalise the principles of the civil law with regard to marriage, and some other important points, the barons made that memorable declaration, "We will not change the laws of England"—words which, like every expression that becomes celebrated, have been used to very absurd purposes.

The charters that were so often granted by the earlier kings to the importunity of their subjects, were partially restrictions of the tyranny of the feudal law, and partially promises to adhere to the old Saxon customs—promises which would not have been so often exacted if they had not been continually broken. The most celebrated of these is that conceded by King John, called *Magna Charta*, or the Great Charter. Its privileges are, in a great measure, constitutional, and it has often been said that it was procured for the advantage of the aristocracy, and not of the people; but it is not without stipulations in favour of the latter, protecting them both from the crown and the nobility. It restricts the tyrannical forest laws, and the exactions by feudal lords from their vassals. The clause which has attracted chief interest, however, is that which says that no free-man shall be affected in his person or property, save by the legal judgment of his peers, or by the law of the land. Legal writers have found a stately tree of liberty growing out of the seed planted by this simple sentence. They see in it the origin of that judicial strictness which has kept the English judges so close to the rules laid down for them in the books and decisions of their predecessors. The judgment by peers is said to refer to jury trial, and it is urged that the whole clause strikes against arbitrary imprisonments, and involves the principle of the *habeas corpus*, by which every man, whose liberty is restricted, may demand to be brought before some competent court, that he may be either convicted or liberated. The great charter has always been a favourite object of veneration, both with the aristocracy and the people, and Sir Edward Coke reckons thirty different occasions on which it was ratified.

Civil liberty may be defined as the permission of such an amount of free action as it is most conducive to the welfare of all that each individual should possess. This is one of the most important objects of the laws, and the circumstances which conduce to its existence are among the most interesting in legal history. In England, the progress of liberty has been in a great measure attributed to the division of interests in the country. The crown had an interest in checking the power of the great nobility. That the exercise of this power was essential to the liberty that has existed in England, is apparent in contemplating the state of France and Germany, where the aristocracy made themselves either quite or nearly independent of the crown, and revelled in the tyranny of their despotic wills unchecked. A very important blow to the power of the aristocracy was accomplished by Edward I. in 1290, by the abolition of the system of sub-feuage. From that day, no vassal of the crown could grant lands to be held of himself, as he may to this day in Scotland—he could only put a new vassal in his own place, as an adherent of the crown. There is evidence that a similar law was passed in Scotland, but the crown was not strong enough to enforce a law that deprived the aristocracy of the dear privilege of being petty sovereigns. The disputes with the church were not without their service. The attempts of the ecclesiastics to urge the claims of their Roman and canon laws, caused the common lawyers to isolate themselves from the slavish doctrines of these systems, and to resist their encroachment with true professional hatred. It was in the universities, of course, that the clergy had their chief influence; and the students of the common law formed themselves into rival institutions, from which originated the Inns of Court. Then there was in the boroughs a separate interest, powerfully pointing towards freedom, and possessed of an influence not to be despised. The tendency

of all these circumstances seems to have been, a gradual return to Saxon freedom, and a fixing of the common law in conformity with the long-cherished feelings of the English people.

That strong-minded and clear-headed man Edward I., whose ambition was so heavy a curse to his neighbours, took a great stride in the establishment of the common law. Of his reforms, as enumerated by Blackstone, we give the following specimens:—"He established, confirmed, and settled the Great Charter and Charter of Forests. He gave a mortal wound to the encroachments of the pope and his clergy, by limiting and establishing the grounds of ecclesiastical jurisdiction; and by obliging the ordinary, to whom all the goods of intestates at that time belonged, to discharge the debts of the deceased. He defined the limits of the several temporal courts of the highest jurisdiction—those of the King's Bench, Common Pleas, and Exchequer—so as they might not interfere with each other's proper business; to do which they must now have recourse to a fiction, very necessary and beneficial in the present enlarged state of property. He settled the boundaries of the inferior courts in counties, hundreds, and manors, confining them to causes of no great amount, according to their primitive institution, though of considerably greater than by the alteration of the value of money they are now permitted to determine. He secured the property of the subject, by abolishing all arbitrary taxes, and talliages levied without consent of the national council. He guarded the common justice of the kingdom from abuses, by giving up the royal prerogative of sending mandates to interfere in private causes. He instituted a speedier way for the recovery of debts, by granting execution, not only upon goods and chattels, but also upon lands, by writ of *elegit*, which was of signal benefit to a trading people; and upon the same commercial ideas, he also allowed the charging of lands in a statute merchant, to pay debts contracted in trade, contrary to all feudal principles." This last-mentioned reform refers to measures for enabling a creditor to get possession of his debtor's land in payment of his debt. How opposed such a remedy would be to feudal principles may easily be conceived, and the boldness with which Edward made his reforms will be felt when it is considered that what he had thus commenced was only completed in 1833. If the debt of a landed proprietor were not substantiated by some bond or other document, his land could not be applied in payment of it on his decease, and it was only in that year that landed property was made fully available for "simple contract debts." The statement that Edward imposed limits on ecclesiastical jurisdictions, refers to the authority which the clergy arrogated regarding wills—mentioned under the head of the canon law. Edward allowed them the charge of the deceased's effects, but compelled them to employ the money in paying his debts.

From the period when we discover any branch of the common law in existence, we find its observance rigorously enforced by the judges. Of course, they had very frequently, as society progressed, to apply it to the wants of an age very different from that in which it was invented; but, in doing so, instead of directly altering the law, which they always viewed as beyond their power, they accomplished the change by a manoeuvre almost peculiar to the law of England, called "a fiction." A fiction may be defined to be the taking for granted that a thing has been done which has not been done, and acting accordingly. For instance, if a man had taken an article in loan or on hire, and refused to give it up to the owner, the legal remedy, by the common law, was a very complicated one. In the case, however, where a man had found another's property which he refused to restore, there was a very expeditious and distinct remedy. It occurred to lawyers, that the kind of process used in this latter case was the very thing that would be most suitable for the other; and therefore, when they brought an action against a person who thus wrongfully detained the goods of another, they stated that he had found them, and the judges, agreeing

in the propriety of the form of action being applied to the purpose, would not allow the party to show that there was no finding in the case. Hence the well-known action of trover, from the French *trouver*, to find. Some curious illustrations of fictions of law will be given when we describe the method in which the courts acquired their jurisdiction.

Fictions were not, however, the only means by which the judges, while adhering apparently to the letter of the law, could adjust it to their own views of the wants of society. A far-seeing judge who looked forward to the probable rise of a new system of transactions, could, by a swaying of the principles of the law that might be quite imperceptible at the moment, adapt them to the new exigencies. It was thus that Lord Mansfield, without the aid of statute, created the law of insurance. There are frequently many underwriters, or insurers to a policy, and had the practice been as it was, each would have had to be prosecuted separately on the occasion of a loss; but Mansfield, by a very slight divergence from previous practice, brought all the claims in a policy into one action—an expedient without which the system as it at present stands could not have existed. This was accomplished by a rule of court known by the name of the consolidation rule, by which all the actions except one is stayed, on the various defendants becoming bound to abide by the issue of that action. In their covert efforts to change the laws, the judges did not spare even acts of parliament. They managed to hit a blow at the power of the aristocracy, by limiting the operation of the statute of entails. When the holder of the entailed estate wished to sell it, he let the buyer bring an action against him, alleging that he had no title. He said he had bought the property from some one—usually the crier of the court—whose duty it was to support his title. The crier being called in, made default, and was nominally adjudged to give the holder under the entail an equivalent, with whom there was no effectual competitor, while the estate was adjudged to the purchaser.

The repositories of the common law are the treatises of eminent lawyers and the reports of decisions. Of the former, there are several of the thirteenth and fourteenth centuries—Glanvil, Bracton, Hengham, and the book called *Fleta*, the authorship of which is unknown. Lyttleton's treatise on *Tenures*, the work of a more matured system, was long the text-book in the practice of the feudal law. It was in the humble form of a comment on this work, that the great Chief-Justice Coke issued the vast treasury of legal learning so familiarly known as "*Coke upon Lyttleton*," a book which is in itself an almost inexhaustible subject of study to the lawyer. The next great name is Blackstone, a man who brought elegant accomplishments to bear on the austere drudgery of the law, and wrote a book, the clear perspicuity of which has made many men acquainted with the laws of their country who would have otherwise remained profoundly ignorant of them. The book has one great defect, that, professing to be not merely an exposition of the laws but an estimate of their worth, it bestows indiscriminate eulogy on all the vices of the system as well as its advantages. The reverential eye with which English lawyers look upon whatever is ancient in the common law, is singularly apparent in the majority of law-books. If any great authority, such as Coke or Blackstone, has treated of a particular subject, whoever afterwards writes upon it seems to be held bound to incorporate all that he has said, not only in spirit but in words. As the passages are not marked as quoted, the effect is a very peculiar one; for the reader, after perusing a few sentences in the easy flow of the nineteenth century, finds himself unexpectedly entangled in the quaint language of the reign of James I., without the slightest hint that he is going to get, not the statement of the author himself, but something taken from Coke or Spelman. Of the reports of cases there is now a vast collection. From the time of Edward I. to that of Henry VIII., they were annually collected by officers appointed for the purpose, and were called

year-books. They have latterly been published by private reporters. As they are all precedents for guidance in succeeding cases, and therefore the source to which the public look for the interpretation of the laws they must obey, it may be questioned whether they should not be officially recorded by persons responsible for the accuracy of their reports. This plan has, to a certain extent, been adopted in America.

Law of Equity.—The peculiar strictness with which the common law was administered, gave rise to the other great division of English jurisprudence—the law of equity. This was originally a system by which relief was given in cases where a strict interpretation of the common law would have produced injustice. It could look to the influence of accidents and frauds when common law could not. A deed, for instance, was lost. The common law courts could hear nothing about what might have been its contents. They could see nothing, know nothing, act on nothing, but the express words of the deed as set before them, and as that could not be found, the party must suffer. Here the court of equity came to his relief, by compelling a "discovery" of the contents of the document. When a trustee was put in possession, common law could not look at him in any other light but as holding for his own behoof; but equity compelled him to do his duty to his employers. Where an obligation was to pay, common law could comprehend its nature and exact performance, but if it was to perform many other act, the assistance of equity was generally necessary. Again, the courts of law might give a remedy for a mischief after it had been perpetrated, but they could not interfere to prevent it. This necessary branch of legal administration came likewise within the jurisdiction of the judge in equity, who, on cause shown, could issue his "injunction."

The origin of this system is as obscure as that of the common law, though it is evidently of a more modern date, having been introduced as a remedy to the evils of the latter. The earlier law-books do not mention it, and it was probably long in operation as a sort of exception to the ordinary course of law, before lawyers would acknowledge it as a system. Its most plausible origin is simply this—that when a person suffered a manifest injury, which the ordinary courts could not remedy, he applied for redress to the sovereign in person. The king's conscience-keeper, or chaplain, became the referee on these occasions, and what he did he sealed, by way of testimony of the royal authority, with the king's seal. Hence the origin of the lord chancellor with his great seal, whose office, in this form, has been traced, or imagined to be traced, so far back as the days of Edward the Confessor. In early times, the chancellors were ecclesiastics, and they thus were in the habit of adjusting their equity, and the form in which they administered it, to the civil law. This occasioned great feuds with the common law courts, which at the commencement of the seventeenth century raged so fierce, that in a case where a remedy was sought in equity from the proceedings of the Court of King's Bench, the lawyers who conducted the proceeding, and a master in Chancery, were indicted for an offence. With the assistance of King James, whose legal notions were derived from the civilians, the courts of equity triumphed. The great Sir Edward Coke was then at the head of the King's Bench—a man who, notwithstanding his harsh and tyrannical acts, must still be admired for the bravery with which he supported the strict administration of the law, however high might be the personage who wished to evade it. Whatever may have been the origin of equity, it became at last a fixed system of law. It is a popular mistake that a judge in equity gives his decision according to what is called "the general principles of equity and justice," without reference to strict rules. He is bound down by precedents and rules, and there are many acts of parliament which regulate his proceedings; so that, in reality, equity is but a department of the general system of law.

Statute Law.—We have now to speak of the third branch of the law—statutes, or acts of parliament. The

constitution of the legislature by which they are passed does not belong to the present subject; it need only be observed, that to be law, every word of an act requires to have the consent of the three branches of the legislature—the sovereign, the lords, and the commons. In very early times, acts of parliament seem to have been petitions by the parliament acceded to by the sovereign. The parliament was convened to supply the king with money, and while it kept him in suspense, it sometimes prepared a petition against grievances, to which a needy monarch found it prudent to accede. It became a practice for the judges, at the end of a session of parliament, to convert the substance of the “petitions,” or “bills,” which had been acceded to by the king, into acts. This practice was fraught with manifest danger, the judges having the power, when parliament had ceased to sit, of altering the intended provisions. To remedy this, the plan now followed was adopted, of making the bill contain the exact words which it was intended should constitute the act. Singularly enough, the bill is still in the form of a petition, and when it is made an act, all the alteration that takes place is, that the words “May it therefore please your Majesty,” are taken out. A bill may be introduced either in the House of Commons or in the House of Lords. It is a rule, that all bills affecting personal station—such as bills of attainder for treason, bills for naturalising foreigners, &c.—shall make their first appearance in the House of Lords. The commons possess the more substantial privilege of originating all bills of supply, or for the levying and appropriation of taxes. The privilege is jealously guarded, and it is usual, should the House of Lords amend such a measure, for the House of Commons to refuse to take it into consideration again, and to authorise their speaker to throw it over the table. About seventy years ago, in the case of a bill for the protection of game, the House of Lords thought fit to raise the penalties higher than those sanctioned by the lower house, and as the money went to the exchequer, the commons considered this an infringement of their privileges, and acted accordingly. All measures involving taxation originate in what is called “a committee of supply,” in which the house is presumed to be sitting, not to debate great questions, but simply to transact pecuniary business. In the case of the introduction of any ordinary bill, amending the law, into the House of Commons, the first stage is, to obtain leave from the house to “bring it in.” In the House of Lords, a member may move a bill without previously obtaining leave. On a bill being brought in, the next step is the first reading. A member moves that it be read a first time. If there be a party in the house bitterly opposed to the principle of the measure, it may be opposed in this stage, and a debate and division will of course ensue. If the objections be merely to the details, they are reserved for a future opportunity. On its passing this ordeal, the bill is ordered to be printed. The next ordeal is the second reading, after which the bill is referred to a committee of the whole house, to be examined. In this committee, as in a committee of supply, the body is the same in every respect as that which constitutes the House of Commons, but the members are considered as having assembled, not to debate general questions, but to enter on a business-like examination of the various clauses of the measure. When the committee have examined all the clauses, the next formality is, that they report to the house, and that their report be received. It is then moved that the bill be read a third time. This stage is, in disputed measures, generally the last trial of party strength. If the third reading is carried, there is still another motion, to the effect “that the bill do pass,” and this motion is seldom opposed. On the bill passing one house, it is conveyed to the other, where it has to pass through the same succession of readings. When amendments are made on a bill after it has passed through one of the houses, in that to which it is then sent, it must be re-transmitted to the house where it first passed. That house may accede to the amendments, and so let the bill pass; or it may reject the

whole measure in consequence of them; or it may, adhering to its first opinions, hold a conference with the other house, with a view to a settlement of differences. When a bill has passed both houses, its next step is the royal assent, which may be given either by the sovereign personally, or by commission.

A bill that has received the royal assent, becomes a law, the operation of which commences from the moment when the consent is adhibited, unless another point of time be stated in the act. All the statutes of a session are ranked in order, according to the date at which they have received the royal assent; and the whole set are distinguished from others by the year of the reign in which they have been passed. Technically, the whole legislation of a session is called one act, and each statute, or act, according to the common acceptance of the term, is called a chapter of it. The privilege of printing the statutes in their original state, without note or comment, is reserved to the king's or queen's printers. In the printed edition of the statutes, each chapter is divided into sections. This arrangement has been adopted by the printers for convenience of reference, but in the original copy of the act there is no such division—the whole is a continuous manuscript without break. Nor is the division into chapters even authoritative. The consequence is, that when a new act is passed, making alteration on some part of a previous one, instead of specifying the chapter and section that is altered, it describes the act vaguely, as an act passed in such a session, for such a purpose. Thus, in 1839, an act was passed to alter a section of the Patents Act, passed in 1837. For any ordinary purpose, this would have been called an act to amend the seventh section of the act 5 and 6 William IV. chapter 83; this would have led to the exact point at once: but as there are no such things as chapters and sections known in law, the legislature could only give a roundabout description, thus—“An act to amend an act of the fifth and sixth years of the reign of his late Majesty William IV., intitled an act to amend the law touching letters-patent for inventions.” Sometimes, there is a series of acts, the latter ones amending those that have preceded them, so that the titles are involved in almost inextricable confusion. Even where the acts are divided into sections, as they are by the printers, it is found very difficult for lawyers to unravel their meaning, and to unprofessional people they are often a sealed book. A section generally consists of but one sentence, and as it has often to give a long narrative of things that must be done, independently of circumstances, and others that must be done in particular cases, and others that may be done but are not imperative, and others that must not be done, &c., the comprehension of the full meaning of the sentence requires a strong mental effort. Among the statutes, there are individual sentences which, if printed in the form of an ordinary novel, would fill a hundred pages.

There are some acts which are passed every session in the same terms, such as the Mutiny Act, the indemnity for neglecting to take the oaths, &c. Independently of these, the statutes now passed in a single year generally fill a quarto volume of about 500 pages, very closely printed. Besides these acts, which generally either apply to the whole empire, or to some one of the great national divisions of it, there are annually passed several folio volumes of statutes, called “Public Local Acts,” consisting of the police acts of the various towns, and acts for the construction and management of harbours, turnpike roads, bridges, gas-works, water-works, railways, &c. It is by virtue of legislative authority only that monopolies can be constituted in such cases, and that individuals can be compelled to sell their property for the use of public works. Hence, this is a separate branch of the statute law, comprising several hundred volumes.

The necessity of consolidating together the various statutes on different subjects, has from time to time been felt and expressed by the first legal statesmen of Britain. Lord Bacon, in whose days the statute law did

not occupy a twentieth part of its present bulk, spoke with alarm of its overgrown size, and recommended that the whole ought to be abridged before it should become unmanageable. Already something has been done. The revenue acts, which occupy a large portion of the statute-book, were partially consolidated in 1826. About 400 acts relating to the customs, and similar matters, the prevention of smuggling, registration of vessels, &c., were repealed, and the new regulations on the various heads were consolidated in eight acts. To these acts, each subsequent session has generally made some addition; but to prevent confusion from this source, a very simple remedy has been devised. When there have been several additions made to an act, a new one is framed, embodying the whole contents of the old act, as altered by the subsequent ones, and then all previous legislation on the subject is repealed. Thus, in 1833, all the customhouse acts were a second time consolidated; that is to say, the acts of 1826, with the additions and alterations made to them by later acts, were embodied together in a set of new acts, so that no one, in consulting the customhouse laws, can have to go farther back than 1833. Measures are no doubt in preparation to extend this principle to other departments. At this moment, there are upwards of 120 stamp-acts in operation, one of them as old as the reign of William III. The existence of these confused masses of legislation effectually prevents people from being able to act up to the laws, however willing they may be, and their protection is frequently in other people being equally ignorant of the laws that are broken. Invidious investigations into antiquated laws, are thus occasionally the means of subjecting individuals to great hardships, by bringing punishment upon them which no foresight could have averted. Hence the trade of what are called common informers, whose vindication of the law has too often the effect of merely heaping calamities on individuals, instead of producing a uniform observance of the laws. The pursuit is a very unpopular one; but when laws are in every respect just and good, it is difficult to see how the enforcement of them can be other than an advantage; and it would appear to an unprejudiced stranger to be a somewhat contradictory practice, first to make laws, and then teach society to hate and punish those who put them in force. As society advances in intelligence, the necessity for the reform of the whole system of law, and its simplification into one comprehensive code, will become more apparent, while the mode of administering the law in courts will also be seen to require revision. Every thing at present indicates that we are approaching the point when these important steps must be taken.

English Courts.—We have now to notice the various courts of law in England. The House of Lords must be mentioned as a general court of appeal from the whole kingdom. There is only one set of superior judicatures from which a reference may not come before it in some form or other—the criminal courts of Scotland. The origin of parliament is connected with the great council of the feudal kings, which gave them advice both in legislative and judicial matters. When parliament was separated into two houses, the judicial business adhered in general to the upper, and probably at the instigation of the bishops, the Lords adopted the power of administering oaths, which was not possessed by the Commons—a circumstance which more distinctly marked their judicial character. To bring causes which have passed through the hands of learned judges under the direct cognisance of a body consisting of clergymen, soldiers, and young men of fashion, would be too preposterous to be practically adopted; and though the appeal is nominally taken to the House of Lords, it is heard and decided on by one of the eminent lawyers, of whom there are always several in the house, and generally by the Lord Chancellor. Independently of their powers as judges of appeal, the Peers act as a criminal court in all cases where a peer of the realm is tried for a

capital crime. They are formed into a temporary tribunal for the occasion, presided over by a judge called the lord high steward. This official is properly the judge, the peers acting as a jury, and giving their verdict on the question of guilt. The directly feudal origin of this relic of ancient practice will be at once recognised.

The principal courts of first resort, are naturally divided into courts of common law and courts of equity. The former are three in number; the King's or Queen's Bench, the Common Pleas, and the Exchequer. Each has a chief, and four assistant judges, called puisne or junior judges. These courts date their origin to the Conquest. On feudal principles, the Norman kings called all the principal causes which had, under the Saxons, proceeded before the county courts, to be decided in their own hall, or court, by their own great council, which was presided over by an officer called the justiciar. This court, called the *Aula Regis*, or King's Court, at first followed the king's person, a great inconvenience, removed by Magna Charta, which fixed it permanently in Westminster. Under Edward I., the system was adopted of sending deputations from the court twice a-year, to try cases in various parts of the country. Under the same monarch, the jurisdiction of the court was split into three parts. To the justiciar, afterwards called chief-justice, were assigned the pleas of the crown, as they were termed, involving all offences; and being the highest judicial officer in point of rank, his court was appointed to have cognisance over the two others. The matters connected with the exchequer, viz. the regulation of the royal domains, the collection of duties and other taxes, were committed to judges called barons, presided over by a chief-baron. All questions about the possession of land, and other litigations between one citizen and another regarding matters of property, were called "common pleas," and were committed to certain justices, presided over by a chief-justice.

The King's or Queen's Bench is thus the chief criminal court, and the Exchequer is the principal tribunal for revenue matters; but these courts are by no means restricted to the departments to which they are so assigned—they possess, concurrently with the common pleas, a jurisdiction in all ordinary questions of common law. The manner in which they obtained this power is one of the most extraordinary circumstances in the history of the laws of any country. The instruments made use of were, as has been hinted, the fictions, described as a peculiarity of the English law. To get at the real motives which were at work, it is necessary to recollect, that formerly not only the judges, but all the officials connected with the several courts, were paid by fees, the amount of which depended on the extent of business transacted. They were thus like so many tradesmen keeping shops for the sale of justice, each anxious to keep a large supply of whatever was most wanted, and to serve the public on the most tempting terms. In this manner, the courts of law undersold the courts of equity by not demanding any sanction, such as an oath, for the truth of what litigants declared in their pleadings. An arduous run for business was carried on between the three common law courts, the accounts of which, as given in the legal histories and law-books, are infinitely grotesque. The extent to which a court could carry its jurisdiction by these means, depended less upon reason than upon the muscular power of those officers of the court who enforced its decrees. The Exchequer, when it attempted to levy taxes, was told occasionally that the person charged with them could not pay, by reason that his debtors had not paid what they owed him; while he hinted, that if the Exchequer wished his money, they had better assist him in recovering it. On this, it became the practice of the Exchequer to assist those who were in debt to the crown to get payment of the money due to them. It occurred to some ingenious lawyers, employed to recover debts, that if they stated to the Court of Exchequer that certain clients were debtors of the crown, and could not pay by reason of their own debtors not satisfying their

demands, the court would make very little inquiry into the truth of the statement, but would adjudicate in the case, and levy the money forthwith. The court made so little inquiry as to the truth of the case, that it would not allow the statement to be contradicted, however inaccurate it might be; and down to the year 1832, when one brought an action in the Court of Exchequer, it was a matter of form that he should say he was a debtor to the king, and that he could not pay his debt, unless an obligation, incurred in his favour by the defendant, were fulfilled. The jurisdiction of the King's Bench was limited to cases that were either purely criminal, or had some connexion with offences. When any one, however, happened to be in the prison of the King's Bench for an offence, there was no means of getting at him but through that court; and so the plan was devised, of stating that a man was in the King's Bench prison when he was not. "And in process of time," says Blackstone, "it [the Court of King's Bench] began, by a fiction, to hold plea of all personal actions whatsoever, and has continued to do so for ages: it being surmised, that the defendant is arrested for a supposed trespass, which he never has, in reality, committed; and, being thus in custody of the marshal of the court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the marshal's custody the defendant is not at liberty to dispute." These fictions were not abolished until the year 1832, when, by act of parliament, an uniform process was established in the three common law courts. An appeal lies from the decision of any one of these courts to the judges of the other two, who, when met to decide on such appeals, constitute a court called the Exchequer Chamber. Fourteen of the fifteen judges who form these common law courts hold the assizes in the various county towns—in some of them twice, and in others thrice a-year. Here they act both as civil and criminal judges. Offences committed in London and its vicinity are tried by a tribunal lately created, called the Central Criminal Court.

The origin of the authority of equity tribunals has been already considered. The principal establishment of this description in England is that of the Chancery. It has in it three distinct courts, and three judges—the chancellor, the vice-chancellor, and the master of the rolls. Formerly, all proceedings in bankruptcy centered with the lord chancellor, but the increasing importance of this class of business rendered it necessary to appropriate a separate court to the purpose. This was accomplished in 1832 by Lord Brougham's act. The term Bankruptcy is in England confined entirely to persons engaged in commerce; and the jurisdiction of the court is so limited. Previous to its formation, however, it had been found expedient to create a court for the relief of insolvent debtors who might not be engaged in trade, on their giving up their property to their creditors. By Sir John Campbell's act for restricting imprisonment for debt, the practice of relieving insolvent debtors was improved, nearly on the model of the Scottish system of *cessio*, and a bankruptcy code was applied to debtors who might not be tradesmen. The utility and importance of the Insolvent Debtors' Court were thus materially enlarged. Another court was lately brought into existence, called the Judicial Committee of the Privy-Council. It consists almost entirely of the judges of the other courts. Its principal jurisdiction is in appeals from the colonial courts, and the Court of Admiralty. This Court of Admiralty has jurisdiction in maritime contracts, and crimes committed on the high seas. Having to deal with matters in which the inhabitants of this and of other countries are jointly interested, it professes to follow, not the special law of England, but the general commercial law of modern Europe, founded on the Roman law. In time of war, the court receives a commission to adjudicate regarding prizes taken from enemies, or from neutrals committing breaches of neutrality. Besides all the tribunals already mentioned, there are ecclesiastical courts in the two archiepiscopal provinces of Canter-

bury and York. In the former, there are the Court of Arches, the Prerogative or Testamentary Court, and the Court of Peculiars; in the latter, the Prerogative Court and the Chancery Court. There are also many inferior ecclesiastical courts. The chief jurisdiction exercised by these tribunals, besides questions of ecclesiastical discipline, is in matters relating to succession to moveable goods. If we were to complete the list of English tribunals, it would be necessary to include the justices of peace, who, besides many special powers in revenue and other matters conferred by act of parliament, sit, at the general and quarter-sessions, as judges in minor offences. Then there are various courts, of greater or less jurisdiction, connected with cities and boroughs; and, in some places, establishments called courts of requests, for adjudicating in cases of petty debts.

After having detailed the legal system of England, it is unnecessary to describe that of Ireland, which is almost in all respects a model of it. The bankruptcy system of England was lately ingrafted on that part of the empire, and the principles of the improved Insolvent Debtors' Act were extended to it in August 1840. The chief distinction in the nature of the courts of law, consists in this, that in Ireland a considerable amount of the judicial business is transacted at courts of general session, held quarterly by the justices of the peace, who act under the advice of professional lawyers, called assistant barristers.

LAW OF SCOTLAND.

From what has been already said, it will be gathered that the law of Scotland was chiefly composed of the feudal system and the Roman law. The former was in practice according to the form in which it had adapted itself to the particular customs of the country, the latter was taken from the doctrines of the civilians. The origin and progress of feudalism in Scotland are very obscure. The chroniclers attribute the foundation of the system to Malcolm II., in the eleventh century, but with little probability. It is more likely that, with the resort of foreigners, Saxon and Norman, to the court of the Scottish king, subsequently to the conquest of England, the system was imperceptibly and gradually introduced. The monarchs, who were ambitious of presiding over a distinguished court, gave particular encouragement to the Normans, to whom they granted large fiefs or lordships; and it was natural that they should return the same homage to which they were accustomed in the country of their origin. The whole of the Lowlands, indeed, and a great part of the Highlands, became nearly as thickly adorned with Norman aristocratic names as the broad plains of England; and it was this alien aristocracy that submitted with so much indifference to the claims and encroachments of Edward I. There appear to have been many points on which the earlier laws of the two divisions of the island were identical. In England, however, as we have already seen, the feudal system received many checks, while in Scotland it was allowed to grow rank; and the deference paid to the civil law in the north served to widen the distinction. The alliance and continued intercourse with France, moreover, naturally drew the legal practice in the direction of the example set by that country.

There is little information to be derived concerning the practice of the law in Scotland previous to the sixteenth century. Edward I. probably destroyed some vestiges, through which its history might have been traced; but he seems to have been charged by some antiquaries with the destruction of more than ever existed. He did more, probably, by fabrication than by destruction to poison the sources of Scottish jurisprudence. The earliest alleged collection of the laws, commonly called the *Regiam Majestatem*, bears so near a resemblance to the English work of Glanvil, noticed above, that it is naturally supposed to have been a digest, not of what the laws were, but of what the conqueror wished them to be. The earliest Scottish legal writer, whose works are quoted, is Balfour, who prepared,

about the latter end of the sixteenth century, a compendium, chiefly derived from the *Regiam Majestatem*, the acts of parliament, and the decisions of the court. In the reign of James VI., a commission to make inquiry into the laws, of which the celebrated Sir John Skene—whom Sir James Melville chose as his legal adviser on his embassy to Denmark, because he was “a stout man like a Dutchman”—was a member. They collected and published many acts of parliament, the *Regiam Majestatem*, and other consuetudinary laws, such as the customs of the royal burghs; and Sir John Skene wrote a curious work on the meaning of technical legal expressions. But the first really scientific writer on the law of Scotland was Sir Thomas Craig, whose book on the feudal law was published in 1655. It is a work of great learning and thought, in which the reader is somewhat surprised to find that, though the work professes to be a Scottish law-book, it should derive so much of its learning from the practice of continental nations. The next great authority is Lord Stair, the equivocal statesman of the reign of James VII., whose *Institute*, on the model of that of Justinian, is remarkable for the breadth of its legal principles, and the acuteness with which they are practically applied. Soon after the middle of the eighteenth century, a second *Institute* was prepared by Mr Erskine, professor of Scottish law, more suited to the knowledge of the age than that of Stair, but more dry and formal. Sir Walter Scott has justly denominated Erskine's *Institute* the Scottish “Coke upon Lyttleton.” There were formerly few opportunities of acquiring a legal education in Scotland, and it was the practice for the youth studying the Scottish law to repair to one of the continental universities, among which Leyden and Paris were preferred. On the occasion of the appointment to a chair of law in Aberdeen, in the seventeenth century, Spalding the *Chronicle* says, it was “strange to see a man admitted to teach the lawes, who was never out of the countrie studieing and learning the lawes,” thus expressing his astonishment that any man could be presumed to become acquainted with a system of law on the spot where it is administered. The civil law is still professedly studied in Scotland, but its ancient influence has sunk beneath the progress of commerce, and the increase of statutory regulations, which compel the lawyer to spend much of his time with acts of parliament and reports of decisions.

Scotland has a considerable quantity of early statute law, but not nearly so much as England. Down to the time of the Revolution, the general principles only of the acts had the assent of the assembled parliament—the details were all prepared by a committee called the Lords of the Articles. The older acts are remarkable for their Spartan brevity—a dozen of them could be put into the title of an act of the reign of George III.; and a modern malt or glass duties' act would occupy half the Scottish statute-book down to the reign of Charles II. It was a practice derived from the civil law, that acts of parliament became repealed by disuse, or contrary practice. Since the union with England, the parliament of the united kingdom has legislated for Scotland, and to the acts so passed the above doctrine does not apply. The description of the passing of an act given above, applies to acts relating to Scotland as well as to those which apply to England. It has been felt as a defect in Scotland, that in many cases acts applicable to the whole kingdom are drawn by English lawyers, who do not apply their provisions to meet the peculiarities of Scottish practice.

The earliest superior tribunals in Scotland, were either the parliament, as the king's great council, or a committee of it, acting with the delegated powers of the whole body. There was likewise, as in England, a king's justiciar, whose authority was vast, and not very well defined, especially in criminal matters. Committees of parliament were, in the fifteenth and the beginning of the sixteenth century, sometimes formed into regular courts of justice, in which, however, a certain degree of fluctuation could not be avoided. In 1532, the pre-

sent Court of Session was constituted, on the model, it is believed, of the parliament of Paris. The chancellor, whose principal duties disappeared at the Union, was chairman of this body. It consisted of fifteen judges, including a president, who was chairman in absence of the chancellor. In 1830, the number of judges was reduced to thirteen; and about the same time, the authority of some other tribunals, the chief of which were the Courts of Admiralty and Exchequer, was transferred to the Court of Session. It consists of two divisions, which are separate tribunals. Some of the judges also act as individual judges in courts of their own, in which capacity they are termed “lords ordinary.” An ordinary case, on coming into court, is discussed before a lord ordinary, from whose decision there is a reference to one of the divisions of the “Inner House,” as it is termed, where the remaining judges sit collectively. From them there is an appeal to the House of Lords. There is no such conventional distinction as that between law and equity known in Scotland, and hence English lawyers, who are apt to measure all other systems by their own, absurdly enough speak of the Court of Session as a court “both of law and equity.” Besides the usual adjudication of litigated cases, there are two very useful descriptions of action peculiar to this court. The one is called an action of “declarator,” which a person who is puzzled about any difficulty, and is afraid of committing an illegal act, may bring, to have the law as to the point declared, and his course of action made plain; another is called a “multipoleinding,” which may be raised by a man having money in his hands which more than one person is claiming, that he may know to whom he can legally pay it. Trial by jury was not, until very lately, added to the jurisdiction of this court. It is limited to certain descriptions of cases, and is far from popular.

The principal criminal court is the Court of Justiciary, consisting of seven of the judges of the Court of Session, who sit in Edinburgh, and commission some of their number to hold circuits in the country. Almost all offences in Scotland are prosecuted by a public prosecutor; there is no grand jury, and the ordinary jury, consisting of fifteen, give their verdict by a majority. The criminal law is partly statute, partly founded on long usage. There are many offences which, by this latter portion of the law, are punishable with death, if the prosecutor do not restrict the extent of punishment to be awarded, which he now does in almost every case except murder. The sheriffs, or local judges of counties, have important judicial powers, both civil and criminal. The former extends to every description of dispute regarding property, except what refers to land. The powers of these judges have lately received extensive additions, especially in matters of insolvency and bankruptcy. They do not employ a jury, except in criminal cases, in which their power of inflicting punishment does not exceed imprisonment. They hold small-debt courts, where questions of debt to the amount of £8, 6s. 8d. are summarily decided. The magistrates of royal burghs enjoy powers somewhat analogous to those of sheriffs. The authority of the justices of peace in Scotland is not so extensive as it is in England.

There has latterly been some indications of the assimilation of the legal usages of Scotland to those of England, and it is highly desirable that an end should speedily be put to all existing diversities.

THE FRENCH CODES.

The ancient laws of France were a mixture of the civil, feudal, and canon law. Partly they were the doctrines of the authorities on the civil law, and partly they were the ordinances issued by the various monarchs. By far the greatest portion, however, in bulk, consisted of the peculiar feudal customs of the various provinces. In these the feudal system was sometimes retained in so high a state of purity, that the collections of provincial customs are esteemed excellent authorities on the subject. But it was not merely in each province that there was a local custom. The power of the crown,

or any other paramount legislature, was so feeble, that wherever an assembly of men were held together by one common tie, as where they were co-vassals of one lord, or members of the same civic community, they had in some measure a code of laws of their own. The royal codes, which existed on a large scale, are estimated at about 300, but of the number of inferior local customs it would be impossible to make an estimate. Voltaire observes, that a man travelling through his country has to change laws as often as he has to change horses, and that the most learned barrister in one village will be a complete ignoramus a few miles off. The seigniorial courts were divided into three grades, according to the extent of the penal authority exercised by them. The principal courts of law were the parliaments of the respective provinces. Seats in them were generally held by purchase, or were in the hereditary succession of great families, who thus constituted a species of professional nobility. The decrees of these bodies were often baffled or reversed by the royal authority, exercised in the well-known form of *lettres de cachet*. These alterations of the decisions of the courts, however, were performed not as a judicial revision, but by the simple authority of the king; and thus the parliaments, being subject to no judicial control or responsibility, adhered but slightly to fixed rules of law, and often acted according to their own will and discretion. The jury, even so much of it as may have existed under the old feudal form, had entirely disappeared, and proceedings were conducted in secret. Criminal investigations, instead of terminating in a conclusive trial as in England, were protracted through a lingering succession of written pleadings and secret investigations, from which the accused could never calculate on being free. The torture was extensively employed; but in the general case, only when there was as much circumstantial evidence as would justify a conviction in this country.

The whole of this system was swept suddenly away before the tide of the revolution, but amid the troubled times that succeeded, it was long ere rulers could find peace and leisure for the erection of a substitute. In 1800, Napoleon appointed a commission to draw up a project of a civil code. The project when prepared was circulated for comment and suggestion, and was afterwards, along with the observations made on it by the different courts of law, discussed in the council of state and the tribunate. Thus was formed the *Code Civil*, or civil code of France, more generally known by the term *Code Napoleon*, which was applied to it under the empire. Nearly at the same time, and in the same manner, was framed the *Code de Procédure Civile*, or code for regulating the form of process in civil actions, and specifying the jurisdictions of the various courts. Being a subject more connected with technical detail, and involving less of general principle than the civil code, its provisions were left almost entirely to the arrangement of the lawyers. Besides the technical directions in which lawyers are almost wholly interested, there are in this manual many which concern the ordinary proceedings of citizens at large, such as directions for the order to be taken regarding the effects of a deceased person, &c. This code is generally accompanied by a table of fees in law proceedings. In 1807, another code was promulgated, called the *Code de Commerce*, consisting of 648 sections. This is the commercial code of France, regulating partnership, bills and notes, banking, shipping, bankruptcy, &c. By this code provision is made for merchants choosing boards or courts from among their own number, called *Tribunaux de Commerce*. The jurisdiction of these courts, which are very numerous, extends to questions between merchants, and disputes arising out of commercial transactions. In criminal legislation, a different order was pursued from that adopted in the civil; the procedure code was prepared and adopted before the crimes to which it was to apply, and the punishments it was to enforce, were defined. The *Code d'Instruction Criminelle* was promulgated in 1808, and the *Code Pénal* in 1810.

Such were the laws issued under the government of

Napoleon, commonly called *Les Cinq Codes*, or the Five Codes. There are other collections of regulations, which should be added to make up a complete body of French laws—a military code, issued by Napoleon; regulations concerning woods and forests, issued under Charles X.; various laws as to the press and theatrical exhibitions, and alterations of the penal code, issued under the government of Louis Philippe, &c. It is simply in the Five Codes, however, passed under Napoleon and confirmed at the restoration, that the modern laws of France are known to Europe at large. They are generally published in a small, thick, closely-printed volume; and for the conciseness, clearness, and elegance of their language, and their intrinsic merits, they are a favourite subject of study with many British lawyers, while there are few places in civilised Europe in which they are not generally known. Independently of the division into books and sections, the paragraphs in each code are numbered straight on from the commencement, an arrangement which gives peculiar facilities for reference. Thus there are in the civil code 2281 consecutively numbered paragraphs. In a country where the material of the law is so gigantic as it is in England, it is of the highest interest to mark the practical working of this grand effort at simplification. To an unlearned person in this country, it is a much easier thing to know the law of France on any particular point, than the law he is living under. If an English lawyer is asked a question, his answer involves references to commentaries, decisions, and statutes innumerable; but in the general case, the answer of a French lawyer bears simple reference to such a paragraph of such a code.

The French codes adopt the phraseology of the Roman law and many of its principles. The most striking deviation from the previous law of France, and the present systems of other countries, is perhaps in the rules respecting succession. The children succeed to equal shares of the parents' property, whether it consist of land or moveables; and if there be no legitimate children, illegitimate children may succeed. The parent is limited in the disposal of his property by will. He can only bequeath the half if he have one legitimate child, and the third if he have two. Restrictions somewhat similar are to be found in other countries with respect to moveable property, but not as to land. The effect which the extensive partition, naturally occasioned by this law, has effected, and may effect, in France, is a subject of great interest to political economists. In the mercantile law there are several provisions unknown in this country, such as registers for hypothecs or securities held over moveable goods or merchandise, and societies "en commandite," or partnerships in which certain managing members are responsible for the obligations of the company to the extent of their whole property, while the sleeping partners who advance money are not responsible beyond the amount of their shares. The chief improvement in the criminal law effected during the revolution, and sanctioned by the code of instruction, was jury trial, to which Napoleon was much opposed: the system, as finally settled, bore more resemblance to the Scottish than to the English form, prosecutions being conducted by public prosecutors, there being no grand jury, and the jury of final trial deciding by a majority. In other respects, the criminal law is more remarkable for its austerity than for its subserviency to the general good of the public. With Napoleon, though that object was not neglected, it was made secondary to the consolidation of his own power; and offences are measured less by their pernicious effects on society at large, than by the trouble or danger they might occasion to rulers. Hence was adopted in many cases the stern and simple method of putting arbitrary power over criminals into the hands of the administrators of the law, while punishments of the highest kind were reserved for offences against the authorities.

POLITICAL ECONOMY.

DEFINITIONS.

POLITICAL ECONOMY is the science which teaches the manner in which nations and individuals acquire wealth.

Wealth is any thing which is capable of gratifying our desires, and of procuring for us, by exchange, some other object of gratification. Some objects are capable of gratifying our desires, but are incapable of procuring for us any other objects in exchange. Such are air, the light of the sun, and, commonly, water. Others are capable, not only of gratifying our desires, but of procuring for us other objects in exchange. Such are fuel, cloth, salt, wheat, iron, money, &c. It is only articles of this latter class that are denominated wealth.

Of Value.—That quality in any object which renders it capable of gratifying our desires, is called its *value*. Thus, the value of air consists in its power to support life; the value of water consists in its capacity to slake our thirst, and in its utility in the several purposes in the arts. The value of fuel consists in its capacity to impart to us warmth, &c.

When this value is considered simply as a capacity to gratify human desire, it is called *intrinsic value*.

When it is considered as a capacity to procure for us something else in exchange, it is called *exchangeable value*.

Things which are every where abundant, and which require no aid from human labour to render them capable of gratifying our desires, have only intrinsic value. This is the case with air, the light of the sun, &c.

On the other hand, things which derive their power to gratify our desires from human labour, and which are found only in particular places, have always exchangeable value.

The reason why these latter have exchangeable value is evident. If I, by my labour, give value to something which had no value before, I have a right to the thing in which this value resides. And, inasmuch as I have bestowed my labour upon it, I will not part with it for nothing. Hence, if any one wants it, he must offer me in exchange something on which *he* has bestowed a similar amount of labour, or else something which I could not otherwise procure, without bestowing upon it an equal or a greater amount of labour. Thus, if I have spent an hour in catching a fish, I will not give it to my neighbour for nothing, or for air, or sunlight, which I can have for nothing. I will only give it for something which I could not procure with less than an hour's labour. And if he offer me something which I could procure with half an hour's labour, I shall not exchange, but shall prefer to procure for myself the article which he offers me.

And hence we see that when men exchange the products which they have procured with each other, they exchange labour for labour. Thus, when men exchange silver for gold, they give a much larger amount of silver than of gold, because it requires much more labour to

procure gold than it does to procure silver. They give a much larger amount of iron in exchange than of silver, because the labour of procuring silver is much greater than the labour of procuring iron.

And hence we see that when men exchange with each other, the exchangeable value of any thing will be, in general, as the labour which it costs to procure it. Hence the *cost* of any thing, or its *natural price*, is the labour which is necessary to produce it.

This, however, is liable to accidental and temporary fluctuation. Sometimes a much larger quantity of a given product is created than is wanted. In this case, the owner, in order to induce persons to buy, will offer it at a less price than the cost, because he had rather sell it at a loss than lose it altogether. When, in this case, the supply is too abundant, the exchangeable value will fall. On the other hand, when not enough of any given product has been created to supply the wants of the community, the buyers, rather than be deprived of it, will overbid each other, and thus will pay more than the natural price: that is, when the demand is unusually great, the exchangeable value will rise. These causes of fluctuation can, however, exist but for short periods, and the constant tendency of the exchangeable value of any thing will be towards the cost of the labour necessary to create it.

Of Production.—Production is the act by which we give to any object its particular value, or its particular capacity to gratify human desire. Man can neither create nor annihilate any thing; he can only change the form of that which is created. We cannot create iron, but we can extract it from the ore; we can then change it into steel; we can change a lump of steel into knife-blades. Each of these acts, by which a particular value is given to the iron, is called an act of production.

The substance to which any value has thus been given, is called a *product*.

Capital.—The term capital is applied to the material before it has been changed by labour into a product; to the instruments with which this change is effected; to the means of subsistence by which the labourer is supported; and also to the product which results from the application of labour to the raw material.

Of Exchange.—Every man finds it for his interest to labour exclusively at one kind of production. Thus, we see that every man has his own trade or profession. But a man wants a great many other things besides those which he produces himself. The shoemaker produces shoes; but he cannot eat, or drink, or clothe himself, with shoes. Hence he must exchange his shoes for those articles which he needs. Every other man is in the condition of the shoemaker. And hence we see that an immense amount of exchanges must be made every day in every civilised community.

Distribution.—Not only does every man work at a particular trade—it is commonly the case that a great many men must labour together in order to create a

particular product. Every penknife, nay, every pin, goes through the hands of several workmen, and receives a portion of its value from every one of them. When the product has been created, every one is entitled to his share of it. The principles by which this division of the profits is made, is called by political economists *distribution*.

Consumption.—Every product, after it has been created, is put to some purpose. Sometimes it is used for the creation of some other product; as wheat, when it has been raised, is used for the purpose of making flour; or, again, it may be used for the simple purpose of satisfying human desire, as bread, when it is eaten, is used to appease our hunger. The destruction of values in this manner is called *consumption*.

The whole subject of Political Economy may therefore be comprehended under these four divisions—Production, Exchange, Distribution, Consumption.

PRODUCTION.

Production is the act by which we confer upon any object a value which it did not possess before; or it is the application of *labour* to *capital* for the creation of a product.

OF CAPITAL.

Capital is the material which is to be united with industry for the creation of a product, or the *instruments* which are used in the act of production, or the *necessaries and conveniences* by which the health of the labourer is sustained. Sometimes the labourer finds the material in its native state, as the miner finds the ore or the coal in its native bed; most commonly, however, he receives it from some one who has already conferred upon it some value, and it is his occupation to confer upon it another.

The forms of capital are as various as the different occupations of men. The material of the farmer is seed, manure, animals, &c.; that of the manufacturer, cotton, wool, iron, leather, &c.; and that of the merchant, the various substances in which he traffics.

The *instruments* with which these producers labour are very various. The farmer uses ploughs, harrows, and carts; the manufacturer, saws, hammers, and spinning and weaving machines; and the merchant, ships, boats, locomotives, &c.

Besides these, all men require for their *sustenance* food, clothing, shelter, and the various conveniences of life. Viewed in this light, all capital may be included under one or the other of these classes.

Changes of Capital.—Inasmuch as the labour of men is so universally employed in changing capital having one form of value to capital having another form of value, capital must be incessantly undergoing changes. It is no matter how many changes it undergoes, if its value be by every change sufficiently increased to pay for the labour which it cost to effect it.

Increase of Capital.—If a given material undergo a change by which its value is increased, then there is an increase of capital equal to the difference between its former and its present value. I say equal to the difference, because, in the creation of one value, another value is always destroyed, and we are benefited, therefore, only by the superior amount of value which we possess over that which we have consumed to produce it. Thus, the farmer consumes seed, manure, labour, sustenance, in the production of a crop. He has changed one kind of capital for another, and he is enriched by as much as his crop is of greater value than all that it cost him to produce it.

Capital which is undergoing change by which its value is increased, or which is yielding an annual income, is called *productive capital*. That which is lying idle, and neither producing any thing nor increasing in value, is called *unproductive capital*.

Money forms a small but very important part of the capital of all civilised nations. The use of money is to

enable us the more easily to make exchanges with each other. That it forms but a small part of the capital of a country, is evident from the fact, that a very small part of the wealth of any individual consists of money. What is true of all the separate individuals of a community, must be true of the whole community collectively.

Of Fixed and Circulating Capital.—That capital from which the owner derives profit by changing its form or place, is called *circulating capital*; while the various instruments which he uses to produce this change, and from the use of which he derives profit, are fixed capital. Thus, the wheat and the manures of the farmer, the wool and raw cotton of the manufacturer, are their circulating capital; the ploughs, harrows, barn, and land of the one, the machinery and buildings of the other, are their fixed capital.

There is a constant tendency in a prosperous condition of society, to change circulating into fixed capital. The farmer sells his wheat, and with the produce buys more land and better tools, or erects better fences and barns. The manufacturer, with his profits of this year, enlarges his manufactory; and thus, in the progress of society, vast sums are annually invested in roads, canals, manufactories, and various means of practical improvement.

The beneficial result of this tendency is easily seen. Fixed capital is but slowly consumed, and hence the wealth of each generation is transmitted to the next; and, year after year, a country becomes better and better provided with the means for furnishing itself with all the conveniences of life. The superior conveniences which we enjoy in this country, over those enjoyed by the aborigines who long ago occupied it, are owing entirely to the amount of fixed capital which covers the soil. It is thus that the results of the industry of men are transmitted to their posterity, and that the men of any one age are enabled to reap advantage from the skill and good conduct of the men of all ages who have gone before them.

OF INDUSTRY.

Of the Nature, and the different Kinds of Human Industry.

Industry is human exertion of any kind employed for the creation of value.

If we consider the different kinds of value which it is in the power of man to create, we shall see that human industry may be employed in three different ways. Matter may be changed in its *elementary form*, as it is by the farmer when he plants seed and reaps an increase; or in its *aggregate form*, as when a carpenter fashions a piece of furniture out of a log; or in its *place*, as when a sailor carries it from one country to another. The ultimate design of all human industry employed in production is to effect either one or the other of these results. They are frequently denominated agricultural, manufacturing, and commercial industry.

It is evident that every one of these kinds of labour is absolutely necessary, in order to promote the convenience and happiness of man; and also that neither one could prosper without the aid of the others. Were there no agricultural labour, every body would starve. Were there no manufacturing labour, every body would be chilled to death. Were there no labour employed in transporting commodities from place to place, no one could enjoy any convenience except what he had produced himself; that is, though, with great industry and suffering, a few persons might live, yet they would be but few, and these few would be miserably poor. Hence, we see how unwise it is for any jealousy to exist between the farmer, the mechanic, and the merchant. All are equally necessary to each one, and each one is necessary to both the others.

But some men are neither mechanics, nor farmers, nor merchants; they are students, or philosophers, or lawyers, or physicians, or clergymen. All of these men, however, are necessary to society, in ways that

must be generally obvious, and are as well entitled to their rewards as any other useful class.

Of the Increase of the Productiveness of Human Industry by the means of Natural Agents.

By the productiveness of human industry, we mean the amount of product which a human being, in a given time, can create. Thus, if a farmer by one day's labour can raise one bushel of wheat, the productiveness of his labour is equal to one bushel; if he can, with the same labour, raise two bushels, the productiveness of his labour is equal to two bushels. If a cotton-spinner can spin one pound of cotton in a day, this is the amount of the productiveness of his labour; if he can spin ten pounds, this is the amount of it.

Now, it is evident that the greater the productiveness of labour, the better it is for the industrious person and for all his neighbours. Every one knows that it is better for a farmer to own rich than to own poor land, because, with a year's labour on the one, he can obtain a much larger crop than on the other. It is, moreover, better for him that his neighbours also should have rich than poor land, because the richer their land, the larger quantity of their products will they be able to give him in exchange for his products. But the only difference between rich and poor land is, that rich land renders industry *more productive* than poor land.

The case is the same with the other modes of industry. He who spins with his fingers, without any machine, labours very unproductively; that is, in a day he can create but a very small product. He who labours with a spinning-wheel, labours much more productively; that is, with a day's labour he can create a much larger amount of product. And he who uses a still better machine, called a spinning-jenny, labours yet more productively; that is, in a day he can create twenty or a hundred times as much product as he could with a spinning-wheel. In every case, as the productiveness of labour increases, both the labourer and the community are benefited, just as a farmer would be benefited by exchanging a poor soil for a rich one. In both cases the benefit is the same; that is, with a given amount of labour he creates a larger amount of product, he receives better wages for his labour, and at the same time, the community obtains his product at a cheaper rate.

And hence it is that mankind have been, from the earliest ages, endeavouring to invent means by which the productiveness of human labour may be increased. And the condition of mankind is improved, from time to time, just in proportion as these endeavours have been made successfully. Every one knows how much the comforts of an industrious mechanic in this country exceed those of an uncivilised Indian. And the difference is owing to the fact, that the labour of the one is *so much more productive* than that of the other.

Now, there are two ways in which the productiveness of human industry may be increased: these are, first, the *use of natural agents*; and, secondly, *division of labour*.

A *natural agent* is, as its name imports, an agent of nature, or any quality of things which we are able to use in order to accomplish our purposes. Thus, it is of the nature of wood, when set on fire, to give off heat, and heat is the natural agent which we use for the purpose of cooking our food. It is of the nature of steam, when heated, to expand, and, when suddenly cooled, to contract; and hence steam is the natural agent by whose alternate expansion and contraction we create the force which we need to propel boats or machinery. So it is of the nature of water, when falling down from an elevation, to acquire a very considerable force; this force is the natural agent which we use to turn the wheel of a mill. So, the peculiar quality of the magnet is a natural agent. The various qualities of medicinal herbs are also natural agents, though used for a different purpose from those mentioned above.

A *tool* or a *machine* is any instrument by which we

are enabled to avail ourselves of the qualities of natural agents. Thus, an axe is an instrument by means of which we make use of the cutting power of iron. A steam-engine is an instrument by which we make use of the expansive and contractile quality of steam.

In political economy, the principal use of natural agents is either to create or to use power or force, or, as we sometimes call it, momentum. Thus, if a man wishes to row a boat, or chop wood with an axe, he must have strength or power with which to do it. The more strength or power he has, the more work he can do. Thus, a man can do more work than a boy, because he has more strength, or power, or force, to do it with. Now, natural agents are capable of exerting this power, and, by means of machinery, we can direct the manner in which it shall be exerted.

The natural agents which we use for this purpose are of two kinds, animate and inanimate.

Animate natural agents are beasts of burden and draught, as the ox, the horse, the ass, the camel, the elephant, &c.

That these very greatly increase the productiveness of human labour is evident. Every one knows how much more land a farmer can cultivate by means of a pair of horses, than he could by his own unassisted strength, and how much more wheat a man can transport from one place to another with a waggon and horse, than he could carry on his back.

The inanimate natural agents are, as we have said, the various qualities and powers of things by which we are enabled to accomplish our purposes. The most important of these are gunpowder, wind, falling water, and steam.

Gunpowder is used in war, in hunting, and in the blasting of rocks. For the latter purpose it is very valuable in the construction of canals, railroads, &c.

Wind is used as a stationary agent in the common windmill; and as a locomotive agent in the propelling of vessels on the water. It is cheap, and for some purposes very valuable.

Falling water is used very extensively as a stationary agent in almost all works where great power is required. Almost all our nails are made, our wheat is ground, and much of our cotton is spun and woven by water.

Steam, however, is now used the most extensively for the various purposes of the arts, as it possesses many advantages over every other agent. It is capable of exerting any degree of force, from the least to the greatest; it may be used as a stationary or a locomotive power; it may be used on land or on water, and it may be placed perfectly under human control. Its only disadvantage is its expensiveness. Steam is now used to spin the finest thread and the stoutest cable, to weave muslins and to hammer anchors, to propel the largest vessels on our rivers and on the ocean, to draw our carriages, to saw and plane our boards, and, in fact, to accomplish almost all the purposes which require either great or unremitted force.

Inanimate agents are in general preferable to animate agents, in most of the purposes for which power is required. The reason of this will be easily seen. For instance—

1. *They are cheaper.* A steam-engine of a hundred horse power will cost less than the horses necessary to do the labour which it performs, and will cost much less to keep it at work.

2. *They labour without cessation*, while animals require much time for rest and refreshment.

3. *They are safer.* They have no passions, and hence may be governed by fixed and certain laws. A steam locomotive is neither liable to run away nor be frightened.

4. *We can use them without the infliction of pain*, while animals frequently, of necessity, suffer in consequence of hard labour or rapid driving.

5. *They are capable of much more rapid action*, hence there is a great economy of human time.

But this is not all. Men are able not only by the above means to create force, they are also able to de-

vise machines by which the force thus created may be applied. Thus, after a steam-boiler and cylinder have been constructed, we are able to create a force by means of steam; but we still need levers, and wheels, and cranks, in order to enable us to use it. When we have trained horses to draw, we still need waggons to enable them to draw with. All these machines, by which force is directed, are the various modifications of what are called in philosophy the mechanical powers. And, by means of them, we are enabled to wield the force which we have created in any manner that we choose.

Besides these agents for the creation of force, there are various other qualities of things which are of very great use in the purposes of human life. Thus, for instance, some of the metals, when heated, readily melt; and if, in this state, they are poured into a mould, they retain the shape of the mould with perfect precision. In this manner much human labour is saved, or a given amount of labour is rendered much more productive. Were it not for this quality of type-metal, every type must be cut by the hand. This would render types and books very expensive. But now we have only to cut a mould into the form that we wish, and, if the melted metal be poured into it, the type is formed, by cooling, into the precisely corresponding figure. In this manner a single workman can make several hundred types in an hour.

There are various other qualities of things which we use in like manner, but their number is so great, that we have no room here to describe them. By reflection, every person may easily furnish himself with as many examples as he pleases.

Of Division of Labour.

In the preceding sections, we have seen that the productiveness of human labour may be greatly increased, *first*, by discovering the various qualities of things, or, specially, those qualities by which we are capable of creating force; and, *secondly*, by those various contrivances by which the force thus created may be directed and applied. We have one other source of increased productiveness yet to consider—it is division of labour—and its results are, in many cases, as striking as any that have been noticed.

Division of labour, in general, means employing one individual upon one kind of labour, instead of employing the same individual upon several kinds of labour. If we reflect, we shall see that this circumstance forms one of the great differences between savage and civilised nations. A savage does for himself whatever he requires to have done. He is his own philosopher, inventor, and operative; his own farmer, butcher, baker, shoemaker, tailor, carpenter, &c. And the result is, that he is ignorant, hungry, shelterless, almost naked; and that he continues, age after age, without making any improvement. On the contrary, civilised men divide these various occupations, so that one man labours wholly in one, and another man labours wholly in another employment; and the result is, that civilised men, without labouring more than savages, easily obtain convenient shelter, clothing, food, and all the necessities of life.

But still more. Every one who observes any mechanical process, observes that it consists of several parts. For instance, in order to make a knife, the blade must be formed and then polished, the handle must be formed in several pieces, the rivets must be made to connect these several pieces together; and after these several pieces have been formed and prepared for each other, they must be united together into a knife. Now, what is commonly called division of labour in political economy, consists in so apportioning this work, that one person shall labour at only one part of any process.

The division of labour in this manner is found to have a much greater effect upon the productiveness of human industry than could possibly have been supposed. Every man who labours at a trade adopts this plan in part. If a cabinet-maker have a dozen tables to make, he will make all the legs of all the tables at once,

then all the covers, &c., and when all have been prepared, he will put them all together. And if several men were to unite and make nothing but tables, and each one perform but one part of the labour, they could make a great many more tables in a given time, than if each one made a whole table.

The reasons for this increased productiveness are several:—

1. It saves the loss of time and skill, which must result from frequently passing from one occupation to another. After a man has laboured for some time at one thing, he is said to have "got his hand in," and he performs the operation with ease and skill. If he turns to a different occupation, "his hand is out," and he cannot perform it so well. Hence, all the time consumed in acquiring the habit is lost.

2. When a variety of operations is to be performed by the same individual, he must frequently adjust his tools, or pass from the use of one kind of tools to the use of another. This occasions a great waste of time. By performing the same operation continuously, the same tools with the same adjustment will answer the same purpose perpetually. This is specially the case where the adjustment of tools requires not only time but expense, as, for instance, in the use of the blacksmith's furnace. If the smith heat it, and leave it for the purpose of doing some other work, all the fuel consumed after he leaves it, as well as that necessary to bring it again to its proper temperature, is lost.

3. When men confine themselves to a single operation, they acquire a degree of dexterity which could be acquired in no other manner. A man who only occasionally makes nails, will make but eight hundred or a thousand in a day; while a boy who has never done any thing else, will make upwards of two thousand three hundred in a day.

4. Division of labour suggests the invention of tools and machines, by which labour may be rendered still more productive. As soon as an operation is analysed into its simple processes, it is comparatively easy to contrive some way in which to perform either one or all of these processes by a machine. It would have required great skill to construct a machine for making nails before the process was analysed; but let it be divided into rolling, cutting, and heading, and it is comparatively easy to construct instruments by which each of these processes may be accomplished.

5. There is great diversity in the talent required for performing the various parts of a process. Some parts of the operation require great dexterity, and a long course of education; others can be performed by women, and even by children, with very little training. Some require labour worth four or five shillings, and others can be executed by labour worth no more than a few pence per day. Now, without division of labour, all the processes must be performed by labour at the highest price. By division of labour, the manufacturer can employ just the amount and just the kind of labour that he needs. This greatly reduces the cost of production.

The effect of all this is seen in the very low price at which almost all the articles of general use may be obtained. For instance, suppose a lady in New York wanted a dozen needles, and applied to a jeweller or other workman to have them made for her, she could not obtain them at much less than a shilling a-piece. But needles are imported into that city from a British manufacturing town, and sold at about four for a half-penny of our money, notwithstanding all the cost of transportation; and this entirely through the advantage derived from the division of labour.

1. But to this division of labour there is a natural limit. This limit depends upon several circumstances. For instance, a given process consists of no more than a certain number of operations. When it has been divided into as many parts as there are processes, and one part is assigned to each individual, this is as far as division of labour can go. There would be no economy in any farther division.

2. Again, the practicability of division of labour depends upon the capital of an individual or of a country. A man must have accumulated some considerable amount of capital before he can carry on division of labour in any occupation. For instance, suppose that the division requires the labour of ten men, he must have materials and tools sufficient to employ them all. Nor is this all: suppose that it take ten days to finish his product, he must have material sufficient to employ them during all this time, before he receives any thing in return for that product. And if it take a fortnight more before he is able to sell his goods and obtain a fresh stock of material, he must have a capital sufficient to employ them during this time also. It is for this reason that manufactures do not commence with the first settlement of a country, but they must always be delayed until capital accumulates, before they can be successfully established.

3. Division of labour can only be carried on where there is sufficient demand for a product to consume it as fast as it is manufactured. If it would take ten men to manufacture pins by division of labour, but only so many pins could be sold as could be made by one man, the labour could not be divided. This, however, depends upon several other circumstances. For instance, the demand depends upon the number and the wealth of a community. There is a larger demand for hats in a town of ten thousand inhabitants than in a village of one hundred inhabitants. There is a greater demand for hats among a thousand rich men than among a thousand beggars. This is another reason why division of labour and manufactures naturally increase with the growth, and age, and wealth of any country.

And hence we see why roads, canals, and railroads are so beneficial to the industry of a country. By reducing the cost of transportation, they render the price of any commodity as low at one hundred miles distance, as it frequently was before at ten miles distance, from the place of its manufacture. Hence they increase the number of consumers, and, by thus increasing the demand, render practicable the division of labour in cases where before it was impracticable.

Again, it is evident that demand must be greatly affected by the cost of the article manufactured. Costly articles are purchased only by the rich. But the rich are only a small part of the community. Hence the demand for such articles is but small. It is those articles that every one wants, and that every one can buy, that create such a demand as will enable them to be made at the cheapest possible rate. Hence we see that division of labour, and the reduction of price which it occasions, benefits the poor much more than it does the rich. I do not suppose that jewellery, trinkets, rich laces, are much, if at all, cheaper than they were twenty or thirty years ago; while cotton cloth, hardware, woollen goods, and all the manufactured necessities of life, have fallen in price from one-half to three-fourths. This is an immense benefit to those of us who are obliged to spend our money for necessities and comforts, and have none to spend for trinkets.

Of the Benefits of Increased Productiveness of Labour.

The object of labour, as every one knows, is to produce the means of happiness. A farmer labours to produce wheat, rye, fruits, &c.; a cotton manufacturer to produce clothing, and a shoemaker to produce shoes, and so of any other case.

Now, the greater the productiveness of labour, the greater are the means of happiness which the individual, by a given amount of labour, produces. If a farmer expend a year's labour upon a rich soil, his labour is more productive than if he expended it upon a poor soil; that is, with the same labour, he produces in one case five hundred bushels of wheat, and in the other case only two hundred bushels. Every one sees that this is an advantage; and every one would rather own one hundred acres of good soil than one hundred acres of poor soil.

Now, if a poor soil can, by means of manure, or in

any other manner, be changed into a good one, the result is the same as if, by means of improved tools, a farmer were able, by one day's labour, to produce twice as much as he could produce before.

Now, this principle applies just as much to a manufacturer, or any other labourer, as to a farmer. Suppose a carpenter, when he first commences learning his trade, could not make more than one table in a week, his labour would be very unproductive. As he becomes more and more skilful, he can make a table in less time; and at last, when he can make a table in a day, his labour is six times as productive as it was before, and he has the means of procuring for himself six times as many comforts with the same amount of labour. If he be able, by means of a turning-lathe, or a steam-engine, or by division of labour, to make two tables a-day, his labour will be still more productive, and he will be able to procure for himself a greater amount of conveniences.

So, if men spun by hand and wove by hand, were this possible, a man could produce but very little thread and very little cloth. His labour would be in the lowest degree unproductive. But if he invent a spinning-wheel and a loom, his labour becomes at once vastly more valuable, and he can produce ten or twenty times as much as he could before, and he is able to provide himself with a much greater portion of the necessities and comforts of life. If, now, we furnish him with a spinning-jenny and a power-loom, his labour will be still more productive; and as he creates, with a given amount of labour, a greater amount of the means of happiness, a larger portion will fall to his own share, that is, he will be both richer and happier. And the facts show that such has always been the result. The labour of the Western Indian or the Eastern Hindoo is without machinery and without division, and it is of course very unproductive. Hence he is very poor. The whole wealth of the Indian is a blanket and a bow and arrows, and the whole wealth of a Hindoo is a pot of rice and a cotton cloth. How different is the condition of the labourer in this country!

And we also see that it is not beneficial merely for one individual to increase the productiveness of his labour; it is beneficial to the whole community that the sum-total of industry should be as productive as possible. Would it not be a benefit if the crops of corn, and wheat, and cotton, and rice, the products of the fisheries, of the mines, and of the manufactories, during the next year, should, with the same labour, be doubled, so that we might, by a day's labour, procure twice as much bread-stuffs, fuel, clothing, and every necessary and comfort of life, as we are able to procure at present? Now, the whole effect of the increased productiveness of labour, by means of machinery and of division of labour, is to bring about precisely such a result.

And yet more—the benefit of this change is specially realised by the labouring classes. A nobleman in Great Britain is by no means as much better off than his ancestor, as a common labourer in England now is better off than a serf at the period of the feudal oppression and ignorance. The rich and powerful in all countries always have an abundance of comforts and luxuries. They are but slightly benefited by improvement in the productiveness of labour. It is the labourer who is chiefly benefited, because every improvement brings within his power some convenience which was before out of his reach. What difference does it make to a man worth a hundred thousand a-year whether coal costs one or five pounds a-ton, and cotton cloth fourpence or two shillings a-yard. At either price he would be able to procure an abundance. But to the man who is worth but fifty or a hundred pounds a-year, the difference of price is a matter of immense consequence; inasmuch as at one price he would be able to supply himself abundantly, and, at the other price, he would be able to supply himself but very scantily, if he were able, indeed, to supply himself at all. Hence we say that improvements in machinery, by which the productiveness of labour is increased, are specially for the

benefit of those of us who are obliged to work for our living.

The only objection to all this is, that, by increasing the productiveness of labour, we diminish the demand for labour, and that hence labourers are thrown out of employment. This deserves a brief consideration, inasmuch as it has led not only to erroneous views in theory, but to practical wickedness in action.

To settle this question, let us examine the facts. What are the manufactures which now employ the greatest number of workmen, and in which the number of workmen has, within the last twenty years, the most rapidly increased. I think that any one will answer, the cotton and the iron manufactures. But if we were asked in which branches of manufactures has labour-saving machinery been most extensively introduced, we must also answer, the cotton and the iron manufactures. Or we may come to the same result, if we compare the linen with the cotton manufacture. Machinery has been introduced only in a small degree into the manufacture of the one, and very extensively introduced into that of the other. The consequence is, that the labourers in linen are very poorly paid, and are diminishing in number, while the labourers in cotton are well paid, and are every year rapidly increasing. These facts are abundantly sufficient to teach any person what is the natural result of the use of machinery.

The reason of this is easily seen. Suppose that only 10,000 yards of cotton *could be used* in a given district, and it required 100 men to make them. If these 10,000 yards could be made by fifty men, it is evident that fifty men would be thrown out of work. But suppose that, by this change in the mode of labour, the cotton cloth which was sold at two shillings could be sold at one, so that *twice the quantity* could be used, and 20,000 yards were wanted, there would be a demand for just the same number of workmen as before, so that the workman would be just as well off as he was before. But suppose that, when cotton was at two shillings a-yard, only those worth two hundred pounds a-year could afford to purchase it, while, now that it is at one shilling, those worth only one hundred pounds per annum can become purchasers. The number of persons in a community worth one hundred pounds a-year, is more than double that of those worth two hundred. Hence this class alone would create a demand which would place the labourer in as good circumstances as he was before. But to this must be added the demand of those worth a hundred and twenty, a hundred and fifty, and two hundred pounds; and it must be remembered, that each one of these classes will now use more cotton cloth than the class of two hundred did formerly. To this must be added the fact, that by the reduction of price, cotton cloth may be used for many purposes to which it could not formerly have been applied. All these circumstances taken into the account, will show us how it is that the greater the productiveness of industry, the greater will be the wages of labour; and, that the more extensively labour-saving machinery is introduced, the greater will be the demand for labourers.

But this is not all. While the labourer is thus benefited in his wages by the use of machinery, he, and every other person, is equally benefited in another respect. We have seen that, by this means, every product is rendered cheaper. Every one knows how much cheaper woollen and cotton goods, carpets, books, and most of the necessities of life are, than they were a few years since. Not only are they cheaper, they are also better and more elegant. Calicoes, crockery, the various fabrics for wearing-apparel, paper-hangings, and many other things, may be procured at a very reasonable price, and of great beauty of appearance. These benefits the labourer shares with the rest of the community. Hence his share of the advantage is doubled. His wages are raised, and the price of what he purchases with them is reduced. The rich man receives no higher interest for his money than before, that is, his wages remain the same; his only advantage is, that, with the

same money, he can procure what he wants at a cheaper rate.

OF CONDITIONS OF SOCIETY FAVOURABLE TO PRODUCTIVENESS.

It is essential to the promotion of industry that a man should enjoy the reward of his labour. Every man must be allowed to labour as diligently as he can, and to use all that he has gained, provided that he use it innocently.

For these purposes it is necessary that all the property in a community be divided. By this it is meant that every thing belong exclusively to some one. In the first place, the land must belong to particular persons, otherwise it will not be tilled at all. We see this principle strikingly illustrated in the condition of a country inhabited by savages, and also in the state of most *commons*, wherever these exist. No one having any particular interest in the cultivation of any part of a country occupied by savage tribes, no part is cultivated. Were any one to cultivate a patch of such land, he might have his right to the crop disputed, and lose the benefit of his labour. It is impossible for men to exert industry under such circumstances. With a common, again, no one has so great an interest as to induce him to keep the ground in order; hence such pieces of ground generally become nearly waste and useless. The principle may be still more familiarly illustrated. Suppose a cherry tree growing in a hedge-row, and no one's property in particular. No one will be at any pains to protect the young fruit of that tree from the birds by means of network; and every cherry which the birds spare will be taken before it is ripe by idle children. There will be no public benefit of any kind from such a cherry tree. But suppose the tree to become somebody's property. It will then be cared for and protected; and the fruit in due time will be ripe, and become a source of enjoyment as far as it will go.

It is not enough that property be divided; the *right* of property must also be *protected*. By the right of property, we mean the right which any man has over what is his own. Thus, if a man make a table out of his own materials, he has a right to keep that table, or to sell it, or to use it as he will, and no one has a right to take it from him, or molest him in any manner in the use of it. And it is the same thing if he have bought the table, or procured it in any honest manner by exchange.

Now, it is the business of every man in the community to see that no man interferes with any other man's property. This is what we call the protection of the right of property. The whole community have committed this power to the legislators, judges, &c., who are called the government. Hence we see that it is the special business of government to protect individuals from violation of the right of property.

The right of property may be violated by *individuals*, as in the cases of robbing, stealing, house-breaking, &c. Were this allowed, no one would labour at all, because no one would labour for the sake of seeing his property plundered and wasted by thieves and robbers. The case is the same when property is plundered and destroyed by mobs. If a man would not labour for the sake of seeing his property destroyed by one robber, he would not labour any the more for the sake of seeing his property destroyed by five hundred robbers.

Hence it is clear that the industry of a country depends very greatly upon the goodness of its laws and the faithful execution of them. If laws allow of violation of property, all men would soon become thieves instead of labourers, and as thieving produces nothing, there would soon be nothing left to steal, and all would starve. And if the laws be not put into execution, there might as well be no laws, and the result would be the same.

But governments themselves sometimes violate the right of property. This is the case, when, by the mere will of the government, the property of the individual is taken for any purpose whatsoever. Such is the case

in many despotic governments. When this is the case, a people becomes at once dispirited and indolent. Who would labour on the soil through a whole summer, if he knew that he was liable to have his harvest seized in the autumn by a tyrant, as soon as it was fit to be gathered? Thus we see that the most fertile regions of the earth, when under such a government, lie almost uncultivated; the inhabitants are few, and these few are extremely poor. Hence the importance of a good constitution of government.

But suppose that every man be allowed to gain all that he can, he must also be allowed to *use it as he will*. This is evident, because no man will be industrious to gain property, unless he be allowed to use it for the promotion of his own happiness in such way as he likes best.

A man's property are his faculties of body and mind, or his means of industry, and his property or capital. It is necessary, in order to render men industrious, that they be allowed, provided they do it honestly, to use both of these as they choose.

For instance, the labourer should be allowed to work at any trade or as many trades as he pleases, to work in any place that he chooses, and to change his occupation whenever he supposes it can be done for his advantage; he should also not be obliged to change it unless he believe such change will be for his benefit. It is to be supposed that every one understands his own business better than any one else can understand it for him, and, therefore, to oblige him to make any change contrary to his own wishes, will do him an injury, and an injury which is wholly without excuse.

And the same is true of *capital*. Every man that owns any thing has a right to use it as he pleases. No one, whether an individual or a government, has any right to direct him in the manner in which he shall employ it. A farmer has a right to raise just such a crop as he pleases; and a merchant to buy and sell what he chooses, and at such prices as he sees fit. He may ask too much, and may impose upon his neighbours, but if he do so, he will soon punish himself. And though he acts wickedly, yet, as we cannot control him without interfering with the right of property, it is much better to let him alone, than, for the sake of regulating him, to oppress all the other men in the community, and thus, for the sake of punishing one bad man, to injure a hundred good men.

Another condition of society favourable to productiveness, is the intelligence of the people. If they be ignorant, they neither are sensible of the importance of industry, nor know how to exert themselves advantageously. It thus becomes of great consequence that all should be, to a certain extent at least, enlightened by knowledge.

EXCHANGE.

We have thus far considered production, and the means by which, with a given amount of labour, production may be increased. But were this all, the happiness of man would be but in a small degree increased. Were a man to make every thing for himself, or, what is the same thing, have nothing but what he could make himself, though his labour were ever so productive, he would enjoy but very few comforts. Though a farmer, instead of raising a hundred bushels of wheat, could raise three hundred bushels, yet if he did not need for his own consumption more than a hundred, and could not procure any thing else with his additional two hundred, he would be no better off than before, but might as well suffer this additional product to rot upon the ground. His additional labour would bring him no additional advantage, and hence there would be no encouragement to labour. But as soon as he is able to exchange this two hundred bushels more than he can use himself for some other things which he wants, his additional labour brings with it a corresponding reward; and additional productive-

ness of labour brings with it additional comforts and conveniences. Of so great advantage to mankind is exchange. And hence it will be seen that the prosperity of a country, its wealth, and its industry, are very much in proportion to its facilities for exchange. Thus we see that no country can easily grow rich without good harbours on its coast, good roads or canals in its interior; and that its advantages are greatly increased when it is so fortunate as to be penetrated in many directions by navigable rivers. We shall now proceed to consider the nature and principal laws of exchange.

OF THE FACTS IN OUR CONSTITUTION WHICH RENDER EXCHANGE UNIVERSALLY NECESSARY.

1. It is a well-known fact that labour is necessary, in order to render any thing valuable. Every thing valuable around us will, if we reflect, be seen to be the result of the labour of some one. And we have also seen, that he who has laboured has, by means of his labour, acquired a right to the value which he has created. By this we mean that he has a right to do with it just what he pleases.

2. It is also the fact, that every man seems disposed to pursue some one kind of occupation in preference to another. One man chooses to be a sailor, another a farmer, another a mechanic, another a manufacturer, and another a merchant. And we also see, that these different men seem each one to be the best adapted to that kind of business which each one has chosen. And we know that, by the principles of division of labour, there will be a much larger amount of product created when every individual has a separate employment, than when every man is obliged to divide his time between a dozen employments.

3. But while every man is thus intended to labour at one particular employment, and to produce one particular thing, every man needs for his comfort and convenience a *thousand* things. Now, as he labours to produce only one of these *thousand* things, he must procure all the rest by exchange; hence, in order to gratify his desires, he must make nine hundred and ninety-nine exchanges. By so doing, he is able, by labouring, to produce one kind of value, and then by exchange to supply himself with every kind of value that he wishes. In this manner men are rendered happier, inasmuch as every one is enabled to pursue the occupation that he likes best, and, at the same time, to procure whatever he needs for his happiness. And, moreover, as by this mode labour is much more productive, every one procures a much larger quantity of what he desires by the same amount of labour.

We thus see, that in order to secure our physical happiness, there is really as great a necessity for *exchange* as there is for *production*. This rule applies equally well to nations as to individuals. No nation is able to raise within itself one-half of the productions necessary to its convenience. It may have, however, peculiar advantages for producing some one or two articles of general necessity. These are commonly called its staples. Now, it is for the advantage of a nation, as well as of an individual, to devote itself to the production of that which it can produce in the greatest abundance and with the greatest ease, and then to procure by exchange with other countries those articles which it needs, but which they produce with greater ease and in greater abundance. The benefits in this case are of the same nature as in the other. Each nation labours in that department of production that it chooses, and at the same time, by so doing, it is enabled, in greater abundance, to avail itself of the productions of every other country.

Since there is so great an amount of exchange which must of necessity be made, it is evident, from what we have said on the subject of division of labour, that there will be a great saving of labour, that is, the labour of the whole society will be much more productive, if some portion of the community devote itself to the business of conducting exchanges. Thus, if there

were in a given town a hundred families engaged in the various kinds of production, and requiring for their own convenience a great many exchanges with each other, it would be a great saving of time and labour if some individuals should give up all other business, and employ themselves entirely in the business of exchanging. They would then receive the various products of the different producers, keep them on hand, and offer them in barter to such as wanted them, and they would carry the productions of the town to a city, and exchange them for what might be wanted by their friends at home. It may be easily seen that such an arrangement would be a great convenience.

Such arrangements are always made wherever men are industrious and frugal, and hence have any thing to exchange. The men who thus employ themselves in exchanges are called merchants.

Merchants are generally divided into retail and wholesale merchants.

Retail merchants purchase in large quantities of importers or wholesale merchants, and sell again to consumers in such quantities as they may desire. In doing this, they greatly benefit all parties. The wholesale dealer could not afford to break open a barrel of sugar to sell a pound, unless he charged a very high price for his trouble. The consumer could not afford to purchase a bag of coffee, or a barrel of sugar, or a whole piece of broadcloth. And, besides, a man is rarely a judge of the goods he wishes to purchase, and it is much better for him to use the skill of a good judge, than to attempt to judge for himself.

The *wholesale merchant* imports in large quantities from abroad, or purchases in large quantities from the manufacturer at home, and sells to the retail merchant, who, as we have said, sells to the consumer. The importance of this kind of labour in exchange is as evident as the other. The retail merchant could not import from abroad, in so small quantities as he wishes to purchase, unless with much additional expense. One wholesale merchant could import as much as would supply a large number of retail merchants, and with but very little more labour than would be demanded of every individual who only imported the small quantity which he needed for his own sales.

The interest of the merchant requires that he should buy as cheap as possible, that he may sell as cheap as possible; for the cheaper he sells, the more numerous will be his customers. Hence the wholesale merchant will export what he can export cheapest, will exchange his export where he can do it the most to his advantage; that is, where he can procure what is most wanted at home, and where he can do it at the lowest rates. So, the retail merchant knows that the better his goods are, and the cheaper the rate at which he sells them, the greater will be the number of his customers, and the greater the number of exchanges which he will be able to make in a year.

Hence we see that the real interest of the merchant, and that of the whole community, are the same. The retail merchant can become rich in no other way than by purchasing as cheap as he can, that he may be able to sell as cheap as he can; for if he sell dearer than his neighbours, no one will buy of him. And so the wholesale merchant can grow rich in no other way than by sending abroad what is cheapest at home, that is, what is least wanted there, and bringing back what is dearest at home, that is, what is most wanted there. Thus we see that if merchants conduct their business correctly, they cannot grow rich in any other manner than by doing a real service to all the community in which they live.

SOME OF THE PRINCIPAL FACTS IN REGARD TO EXCHANGE.

1. In making exchanges with each other, men proceed upon the principle of exchanging labour for labour. What men can procure without labour, they will give away without demanding labour for it. What they have to labour a day in order to procure, they will not exchange for any thing which they could procure by

labouring half a day. And thus, in general, when one product costs more than another, it is because it requires either more labour, or more skilful labour, than the other to produce it.

Here, however, we should always bear in mind the nature and effect of accumulated labour. If a man labour six months upon a wind-mill, this wind-mill represents the labour and skill of six months accumulated in one machine. If he use this mill for grinding flour, he is entitled not only to the price of his labour per day, but also to remuneration for the use of his accumulated labour. Now, all machinery, all fixed capital of every kind, railroads, canals, &c., are so many forms of accumulated labour; and it is manifest, that for the use of this labour, as well as for the daily labour by which it is put into operation, the owner is entitled to a fair remuneration. And also, it is evident, that, if capital be left free and unencumbered, this kind of labour will, by competition, be brought to yield, like every other capital, no more than its proper and fair recompense.

While this, however, is true in general, it is also true that the exchangeable value of all articles is liable to sudden and limited variations, from the variations of supply and demand. In such cases, sometimes an article will bring more, and at other times less, than the cost of the labour necessary to produce it. These, however, never can continue long, and they in the end equalise and compensate for each other; so that they do not at all invalidate the general assertion, that when men exchange, they exchange on the principle of labour for labour.

2. The exchanger, or merchant, confers no new value on a product, he only saves labour and time to the producer. The article which a merchant buys is not changed in any manner by his labour. He who sells penknives, or calicoes, or sugar, or coffee, sells these articles just as he receives them. And so of the articles which he purchases to export in payment for them. Nevertheless, he is still performing a service of great advantage to the community. Were the farmer, who wanted a scythe, obliged to carry his wheat to the *scythe manufacturer*, and exchange it himself, his scythe would cost ten times what it costs at present. The case is still stronger, if he were obliged to go to Sheffield or Manchester to procure the hardware which he wanted. Hence, although the merchant does not himself add any new value to his wares, yet, by reducing the cost at which they must otherwise necessarily be procured, he does as great service to the community as those who actually produce. He enables other persons to produce twice as much as they would be able to produce otherwise, and this is the same thing to the community as though he were the producer himself.

3. Hence, it will be seen that the more rapidly exchanges are made, the better it will be for the merchant and for the community. It will be the better for the merchant, because he thus, with the same capital, makes a greater number of exchanges in a given time, and thus makes a greater annual profit, while he charges a smaller advance upon each exchange. And hence it is better for the community, because the less the advance which he charges, the less is the price which they are obliged to pay for what they purchase. Thus we see that, in prosperous times, trade is brisk; that is, exchanges are made rapidly, and with the greatest advantage to both parties.

4. There are three circumstances on which the frequency and infrequency of exchanges depend.

1. *The intelligence of a people.*—Every one has a desire for the various means of happiness which God has spread around him, if he know what they are, and how he shall obtain them. Every one, who has read the voyages of the early navigators, must have seen how eager the inhabitants of the newly discovered islands were to exchange, as soon as they beheld the various instruments, and tools, and ornaments of civilised men. And thus we see that newspapers, travelling, and all the means by which information is circulated,

have a great effect in increasing the desire of men to improve their condition by means of exchange; and that they are thus induced to labour more industriously, in order to procure something to offer in exchange for what they want.

2. *Productiveness of industry.*—It is not enough that a man be desirous to exchange; he cannot gratify that desire unless he be able to offer something to the other party which will be accepted in barter. If I desire a barrel of flour ever so much, I can never obtain it, unless I am able to offer to the flour merchant something which he will accept in exchange for his flour. Thus, every one knows that a rich man is able to make a great many more exchanges in a year than a poor man. A labourer who earns high wages can make many more exchanges in a year than a labourer who earns but low wages. A farmer buys many more articles of comfort, that is, makes many more exchanges, in a productive than in an unproductive season. And thus, in general, every one must see that a rich country makes more exchanges, both internal and external, than a poor country; a prosperous, than a declining country; and the same country in a period of successful than in a period of unsuccessful industry.

3. *Moral character.*—Men do not always exchange their products at the same instant, but one or the other frequently waits some time for the return which he is to receive in exchange for his product. This gives rise to a liability to dishonesty. And, besides, where men are dishonest, they will frequently cheat each other in the quantity or the quality of the article which they offer in exchange. Now, where these liabilities exist, they will greatly lessen the number of exchanges. No one, who can help it, will have any dealings with a rogue. Hence, when men are disposed to be rogues, exchanges will diminish. Laws are made to oblige rogues to act like honest men; hence, when laws are just, and are well administered, exchanges will be more frequent than when they are unjust, partial, and unfairly administered. But every one must see that on the moral character of a people, not only their personal honesty, but also the goodness of their laws, depends. Hence we observe that morality, using this word in its most extended sense, is of the greatest importance, not only to success in production but also to success in exchanges.

And the same principles apply to our exchanges with foreigners. If we treat them justly and kindly, and allow them all reasonable means for enforcing their rights, they will come and exchange their products for ours, in preference to going to another country where they would be less favourably treated. Thus we shall be able to procure, on the most favourable terms, whatever we need from other nations, and in this manner reap the richest reward for our industry and moral character. A selfish, exclusive policy, is as self-destructive a policy for nations as it is for individuals.

And, if this be the case, we shall easily determine what are the causes which naturally diminish the frequency of exchanges, or produce a stagnation of business.

If the *desire* for any particular product diminish, the *demand* for it will diminish; hence, those who produce it, and those who keep it for sale, will be unable to sell it. Thus the changes in fashion frequently destroy, in a short time, the entire demand for an article, which, a year ago, was in vogue. Or the diminution of the intelligence of a country will, in due time, produce the same effect on exchanges generally.

The diminution of production during a single year will produce the same effect for that year; and oppression, heavy taxation, or any thing which interferes with production, or diminishes the productiveness of human industry, will accomplish the same result permanently.

And hence it is that, as a nation becomes vicious, unjust, or oppressive, such moral deterioration must produce a diminution of exchanges, in the same manner as it interrupts all other kinds of industry. And thus

success in exchange, as well as success in production, depends much upon the intellectual and moral character of a people.

From what has been said, it will be easy to perceive in what manner a government can best *promote* the business of exchange. It is by promoting the intelligence and virtue of a people—by giving every facility for the increase of the productiveness of industry—by encouraging, in every suitable manner, the establishment of roads, canals, railroads, and means of internal communication—by rendering its harbours and coasts as easy of access as possible—and by giving to foreigners every reasonable facility for the transaction of their business when they come amongst us.

And we see, also, what measures are, in their nature, most likely to *diminish* the number of exchanges. Such are duties on imports, or, in other words, adding to the price of every foreign commodity offered in exchange, obstructing the means of intelligence, refusing the necessary facilities for constructing means of internal communication, imposing unnecessary disabilities upon foreigners, neglecting the condition of harbours and coasts, and, in general, any course of measures by which the article offered in exchange is rendered more expensive, or by which the person who comes among us for the purposes of exchange, is denied any reasonable means for seeking his own interest or happiness.

[Of exchange by means of money, metallic and paper, a full exposition is presented in the sheet entitled, COMMERCE—MONEY—BANKS, to which we refer.]

DISTRIBUTION.

We have thus far considered the mode in which wealth is, in the first instance, produced, and in which, in the second instance, the producers are enabled to exchange it with each other.

It is, however, commonly the case that an article of production is not the result of the labour of one man alone, but of several men united. Thus, several men successively unite in producing a barrel of flour. One owns the land, another sows the seed, another reaps the harvest, another owns the mill in which it is ground, another manages the mill for the owner, another makes the barrel in which it is contained, another transports it to market, and another sells it to the consumer. Now, every one of these must be paid out of the barrel of flour when it is purchased by the consumer; that is, the price of the flour must be so *distributed* among them all, that each one has his just share of the proceeds. The principles on which this is to be done are considered by political economists under the head of DISTRIBUTION.

As all value is the result of capital and industry, it is manifest that we shall comprehend the whole subject, if we treat of *Wages*, or the price of labour, and *Interest*, or the price of capital. Inasmuch, however, as *Capital in Land* is in some respects peculiar, we shall consider it separately, under the head of *Rent*, or the price of land.

OF WAGES, OR THE PRICE OF LABOUR.

Of the General Principles by which Wages, or the Exchangeable Value of Labour, is regulated.

We have already seen that exchangeable value is the cost of any thing, influenced moreover by the effect of supply and demand. We shall therefore consider, 1st, The cost of labour; 2dly, The effect of supply and demand upon it.

I. Of the cost of labour.

Of simple labour.—By simple labour we mean that labour which may be performed by any healthy person without any, or with very trifling, previous education.

1. But it is evident that no person can continue in health without food, clothing, and shelter. We cannot, therefore, procure the labour of any living thing without furnishing those necessities which are required for

the continuance of existence. This is the first thing which enters into the cost of labour.

2. But, besides this, human beings are not qualified to labour until they have attained several years of age. During the period of infancy, they must be supported by the labour of others. Were they not so supported, the whole race of man would in a few years perish. The cost of labour must therefore be sufficient to sustain not merely the parents but also the children. And yet more, men live frequently after they have ceased to be capable of labour. The old must be supported, or they will perish. Hence the wages of labour should be enough to enable the labourer to lay up something to support him in his old age, or else the wages of his children should be sufficient to maintain him after he has become unable to maintain himself.

3. While, however, this is the fact, yet it may be observed, that the cost of labour, or the remuneration necessary to accomplish these purposes, will vary in different climates. In warm climates, where vegetable food is principally used, and where very little expenditure is required either for fuel, clothing, or shelter, wages would naturally be lower than in cold climates, where the expenditures must of necessity be so much greater. This is, however, equalised by the fact, that warm climates enervate the system and relax the physical energies, so that, while you pay a very small sum for a day's work, you receive a very small amount of labour in return.

Such is the natural cost of simple labour, and it will be generally found that by this rule that cost is practically adjusted. Whatever may be the condition of the country, the lowest class of labourers earns but simply sufficient to procure the ordinary necessities of life for the parents and the children.

Of educated labour.—But for most of the occupations of life some sort of education is required. No man can be a carpenter, or a blacksmith, or a jeweller, or a physician, or a lawyer, or a clergyman, without being educated for the particular calling which he intends to pursue. Now, this education is expensive. It costs both time and money. If a man wish to practise a trade or a profession, he must spend several years in preparation or apprenticeship. During the whole of this time he receives no wages, and frequently is obliged to pay for tuition. When he has acquired the necessary skill, he is able to perform more valuable labour than before, and he is entitled to a higher compensation. This compensation would naturally reasonably be adjusted by a consideration of the time and capital which he has expended in his education. The longer the time and the greater the expense of his training, the higher ought to be his wages. It is evident that the wages of such labour must be always greater than those of simple labour, otherwise it will not be produced. No man will spend money in educating his son for a calling which will yield him no higher wages than he could earn without any education.

Such are the principles by which the cost of labour is adjusted. Wages must always be sufficient to support the labourer, and to remunerate him for the expense which must be incurred in acquiring the skill necessary to the practice of his profession.

II. Of the demand for labour.

We shall consider this under two heads—1st, The demand for simple labour; and, 2dly, The demand for educated labour.

1. The demand for simple labour, or that which is indispensable to the production of the ordinary necessities of life, is incessant and universal. Every man requires, either indirectly or directly, the labour which is employed in producing the ordinary articles of consumption for food, clothing, and shelter.

But in order to render this labour available, it must be united with capital. Neither labour nor capital can produce any thing alone. Hence he who possesses capital is always desirous to unite it with labour, and he who is able to labour is always desirous to unite that labour with capital. And it is evident that the larger

the amount of capital which a man possesses, the greater will be the amount of labour which he will wish to procure. He who cultivates five hundred acres of land will require a larger number of workmen than he who cultivates but fifty acres. The iron founder who wishes to manufacture five hundred tons of iron, will require a greater number of workmen than he who wishes to manufacture but fifty tons. And hence, in general, we see that the greater the amount of capital, the greater will be the number of labourers required, that is, the greater will be the demand for labour.

If the capital of a country be too great for the number of labourers, there will be a competition between capitalists for labour. They will overbid each other, and thus the price of labour will rise. Those of the first class will be insufficient to supply the demand for labourers of this class, and a number of labourers must therefore be taken from the second class. And thus, in succession, every class of labourers will be raised one grade. The price of labour will thus be raised throughout the whole community, the condition of the people will be meliorated, a smaller proportion of children will die, and a larger number of labourers will be reared. If this addition do not supply the deficiency, labourers will immigrate from less favoured countries, where the proportion of capital to labour is less.

And, on the contrary, where the proportion of capital to labour is small, there will be a larger number of persons desirous of labour that can find employment. In this case there will be a competition among labourers for work. They will underbid each other, and thus the price of labour will fall. The case mentioned in the last paragraph will then be reversed; the condition of all the labourers will be rendered worse, and many will either emigrate or starve. Many children, and weak and sickly persons, will die of the diseases consequent upon hardship and exposure. In this manner, the number of human beings will be reduced, until the supply of labour is adjusted to the amount of capital, and then the price of labour, or wages, will rise again.

Hence we see that, in order to secure the prosperity of a country, it is necessary that its capital should increase with its population. No matter what may be the present condition of a people, if population increases faster than capital, or if capital be stationary, or specially, if it be diminishing, there must soon arrive a season of great distress among the labouring classes. There will be more labourers than can find employment.

Hence we see the great importance of both individual and national frugality. He who squanders away property in useless expenditure, is annihilating the very means by which the honest labourer might earn his subsistence. Thus, also, of nations. The government that wastes property in wars, or in any other form of unprofitable consumption, is diminishing the capital of the country, and scattering the resources which the toils of the people have accumulated. Every shilling thus spent, is the destruction of so much of the means by which the labourers of the country are to be sustained. Suppose a nation be worth a hundred millions of capital, and that the use of all this capital be necessary in order to furnish employment and the means of subsistence to its population. If it spend ten millions in war, that part of its population which was sustained by the use of that ten millions must be unemployed. Or, if this portion be not immediately thrown out of employment, and the injury be averaged, the price of wages for the whole will be reduced to the amount of this difference; every one will be worse off, and some will be destitute and will starve.

Of the demand for educated labour.—This is substantially dependent upon the same principles. A community needs the services of lawyers, physicians, clergymen, judges, and men of science. Hence there will be a demand for these services. If there be a greater number of educated labourers than is required, the price of the wages of such labourers will fall.

Under contrary circumstances it will rise. When the price of educated labour falls so low as not to remunerate the labourer for his skill and education, the supply will be reduced by the fact that men will turn their attention to some other pursuit.

The demand for these different kinds of labour varies with the condition of society. The rich and luxurious have greater demand for medical aid than the poor and abstemious. The progress of society renders titles to land more intricate, and exposes men to greater danger from fraud. Hence the greater need of the services of those who have devoted themselves to the study of the laws, and who are therefore qualified to instruct us how we may avail ourselves of the benefit of law.

III. We next proceed to consider the *supply* of labour, both simple and educated.

The amount of labour in any country depends upon the number of healthy human beings inhabiting it. Hence the supply of labour will depend chiefly upon those conditions by which the increase or the continuance of human life is affected. Of these conditions, the most important are the following:—

1. The means of living which may be commanded by the labourer. Where wages are low, and the means of living are with difficulty procured by the labouring classes, the increase of population will be small, nay, population may become stationary, or it may even decrease. When a family, with its utmost labour, in health, can barely provide the means of subsistence, they must all suffer greatly in sickness. In such cases, parents or children very frequently die from the want of common conveniences or attentions. And as sickness is a calamity common to all men, under such circumstances large numbers of the poor must perish. For this reason, epidemic diseases, especially those of children, are much more fatal among the poor than among the rich. In countries where the wages of the poor are very low, it is not uncommon to find parents who have had large families almost childless. On the contrary, just in proportion as the labouring classes are enabled to provide themselves with all the conveniences of living, will the number of children who are reared be increased.*

And besides, labourers will readily emigrate from other less favoured countries to that in which the condition of the labouring classes is happy and prosperous. In this manner, population will always flow from old to new countries, and from regions where labour is poorly repaid to those in which it receives a more generous remuneration. Both of these circumstances tend, at present, to increase the population of the United States. There the wages of labour are high, and the means of living abundant. Those who are willing to labour can always command the necessities, and frequently the conveniences of life, both for themselves and for their families. Hence a much smaller proportion of children die there than in older countries, and, of course, the population is much more rapidly augmented. And, from the same cause, namely, the high price of labour, there is annually a prodigious amount of emigration thither from the older countries of Europe.

2. The next condition necessary to the rapid increase of population, is the moral condition of a people. Vice is always awfully expensive, and terribly desolating to human life. It matters not how great be the wages of the labourer; if those wages be spent in intemperance and profligacy, his family will starve. In some countries, such as the United States, almost all the suffering of children is the consequence of the vice of one or of both of their parents.

On these two circumstances, therefore—the wages of

* It has latterly been surmised, with considerable probability, that the sinking of a population below a certain point in comfort, introduces conditions which tend to its increase; but the increase produced in these circumstances does not operate as a healthy increase would do, the people being then ill cared for, ill reared, ill educated, and perhaps also dangerous, and therefore injurious to the development of the powers of capital.—Ed.

the labourer and his own personal moral habits—does the increase of population chiefly depend. And, as we have before stated, the supply of labourers is as the increase of population.

The same principles in the main govern the supply of educated labour. If the wages of such labour are sufficient to pay for the expenditure of time and capital necessary to the acquisition of the education, such labour will be produced; that is, men will turn their time and talents in this direction. On the contrary, when the remuneration of such labour is inadequate, men will not prepare themselves to perform it, and those already educated will devote themselves to some other occupation. The supply will thus be reduced so as to correspond with the demand.

Of Circumstances which affect the Rate of Wages in particular Instances.

We have seen that a given amount of capital is necessary in order to furnish employment for an individual labourer. Hence any given amount of capital directed to any one business, will only furnish employment for a correspondent number of labourers. And hence, if any portion of the capital now employed in any one kind of business be withdrawn and devoted to any other kind of business, there will follow a change in the rate of wages in that employment. The wages in the business from which capital is withdrawn will fall; those in the business to which capital is directed will rise. Such is the result of all legislative enactments which affect the employment of capital.

But, besides this more general cause, the price of labour in the several professions is affected by various special circumstances. For instance—

1. By the ease or difficulty, the pleasure or pain, of the employment, and by the estimation in which it is held by the community.

When any trade is in its nature unpleasant, men do not like to practise it. Hence, when we wish to employ them, we are obliged to overcome their reluctance by higher wages. When the performance of the labour is pleasant, many persons are willing to engage in it, and hence, the supply being greater than the demand, the price of the labour falls accordingly.

2. By the skill required in performing the operation. This results from two causes. First, the greater the skill required, the smaller will be the number able to perform the operation. Thus the supply will be small. And, secondly, the longer will be the time spent in learning to perform it, and hence the greater wages will the labourer be entitled to receive.

3. The confidence reposed. In many employments, much reliance must be placed in the moral character, the courage, the discretion, and forethought of the agent. But, inasmuch as these qualifications are not frequently found united in the same individual, the number of suitable candidates for such employments is small. Hence, as the supply is commonly less than the demand, the wages in such employments are high. And, inasmuch as those who have a large amount of capital at stake, find it for their interest to procure such labourers at any price, the wages of such persons will always be much higher than in cases when no such confidence is of necessity reposed.

4. Constancy or inconstancy of employment.

Some kinds of labour furnish incessant employment; others furnish employment only at intervals. Yet, in the one case as well as in the other, division of labour requires that the labourer devote his whole time to his business. Hence, in the latter case, it is reasonable that, for the performance of a particular operation, he should receive a larger remuneration than in the former. We pay more for riding a mile in a hackney-coach than for riding a mile in a stage-coach, because the employment in the one case is constant, and in the other inconstant. A large portion of the time of the driver of a hackney-coach is consumed in waiting for passengers. For this time we must pay our portion whenever we employ him.

OF THE PRICE OF MONEY, OR INTEREST.

Why we pay Interest for the use of Money.

The first question which arrests our attention in the consideration of this subject, is the following:—Why should the use of money have any price at all? As I return to a man the same value which I borrow of him, why should I pay him any thing for having kept it during the interval? This question we shall first attempt to answer.

Every man who labours at any regular employment, possesses two qualities which render his services of value—these are *strength* and *skill*. The first enables him to execute simple labour, or labour of the cheapest kind; the second, when united with it, enables him to execute educated or higher priced labour. But, in order to perform the latter, he requires tools and materials, that is, capital. Without these, he could perform only simple labour. Of what use would be the skill of the blacksmith, without a forge and iron? or that of the carpenter, without tools and wood? or that of the spinner, without a spinning-jenny and raw cotton? Without these, they would be all reduced to the necessity of that labour which could be performed with their naked hands.

Suppose now that I am a blacksmith, and own a forge, tools, and iron, with which I am daily employed, and thus earn the wages both of labour and skill. Were I to lend them to another man for a week, and carry a hod during the mean time instead of working at my trade, and thus lose the profit of my *skill*, he who thus borrows them of me should surely remunerate me for the use of them. Suppose he borrow them for a year, he should pay me for the same reason. And if I have the money with which he can purchase them for himself, and I lend it to him, he should pay me just as truly for the money as for the tools and capital, because if I had not lent it to him I could have established another forge, which I could have made profitable to myself.

And here we may remark, in general, that when we speak of the loan of money, it is in reality not money but other capital that is wanted, and for which we pay interest. Were a tradesman to keep the money which he borrows locked up in his drawer, it would be worth nothing to him. It can be only of use when it is exchanged for something else, which, being united with labour, will yield a profit. The fact is, that every one, as soon as he procures money, exchanges it for tools, or materials, or merchandise. Every one sees that these ought to pay interest, because they are the means of accumulation. Just as much should the money pay interest which is exchanged for them, and for which the owner of the money would have exchanged them, if he had not lent it to another.

Now, it very frequently happens that the ability to labour is possessed by men who have no capital upon which to employ it. And, on the other hand, capital is frequently possessed by men who have neither the skill nor the ability to labour. In such a case, it is manifestly for the interest of both parties to form a copartnership, the one party furnishing the labour and skill, and the other furnishing the capital. By this means both parties are benefited. The labourer earns the wages of labour and skill, instead of those of simple labour; the capitalist derives an income from his property without diminishing it, instead of being obliged to live upon the principal.

Now this takes place in two ways, both the same in principle, although the mode in which the arrangement is made is dissimilar.

The first is the case of wages. Here there is virtually a partnership formed between the capitalist and the labourer. The one furnishes the tools and the material, and takes all the risks of the operation, and divides with the labourer the profits, which he pays in the form of wages. These are generally agreed upon at the commencement between the parties, and are the same whether the operation be profitable or unprofit-

able. This, however, is not always the case. In the whale-fishery, the crew of a vessel receive a *pro rata* proportion of the profits, in the place of regular wages, and of course their remuneration is greater or less according to the success of the voyage.

The second case is that in which the labourer assumes the risk, receives all the profit himself, and borrows his capital from the other, agreeing to pay him at a stated rate for the use of it. This is commonly the case in the borrowing and lending of money. If I purchase a shop and stock it with goods, and employ another to keep it for me, paying him the customary wages, I act in the first-mentioned manner. If I lend him the money by which he purchases the shop and stock, and he trades on his own risk, paying me interest on the amount borrowed, I act in the second manner.

It is the latter case that is to be considered in this place. Here the borrower uses the capital of the lender for his own advantage, and that advantage is equal to the difference between simple labour and labour united with skill. Did he not thus employ this capital, the lender would employ it himself. It is therefore just that he should pay for the advantage which he gains, and of which he, by thus gaining it, deprives the owner.

Of Various Circumstances which affect the Rate of Interest.

We have thus far endeavoured to show that a price, that is, interest, should justly be paid for the use of capital. But we find that the interest of capital is different in different countries at the same time, and in the same country at different times, and in the same country and at the same time it is different in different kinds of investment. To the circumstances which give rise to these differences let us now attend.

I. The rate of interest will be affected by the productiveness of capital.

When a capitalist, by the use of his own capital, can readily make ten per cent. per annum, he will of course charge a higher interest upon it than when he can scarcely make five per cent. per annum. And it is evident, on the other hand, that the borrower will be willing to pay a higher interest in the former than in the latter case, because he will be able to make a higher profit by the use of it. Hence, when land is both cheap and productive, interest will be high, because the investment of capital and labour in land and cultivation will be exceedingly profitable. The same reason operates in other cases.

Whether the productiveness of capital be great or small, supply will affect the rate of interest. When the supply is small, there will be a competition among the borrowers, and the lender will receive the largest possible share of the profits, that is, interest will be high. When capital is abundant, there will be a competition among the lenders; interest will fall, that is, the lender will receive the smallest share of the profits.

Both of these causes tend to produce the high rate of interest so commonly observed in new countries. Land is cheap. It is in its highest state of fertility. All labour bears a very high price, for the results of labour are imperatively demanded; and, at the same time, capital is scarce, while the demand for it is incessant. As a country grows older, these circumstances change, and the interest of money gradually falls.

II. Secondly, another circumstance affecting the rate of interest is the risk of the investment.

When a man parts with his property and places it in the power of another, there is at least a chance that he shall never see it again. This risk should justly be added to the price which is paid for the use of capital. Thus, suppose that the fair compensation for the use of capital in one case were five per cent., on the supposition that it was perfectly sure; if, in another case, there were a risk equal to two in a hundred of its being totally lost, this two per cent. for the risk should be added to the five per cent. for use, and the interest

of the latter loan would be justly seven per cent. So in any other case.

This risk may depend upon several circumstances, as, for instance—

1. *The nature of the investment.* The risk of loss would be less on money lent for the erection of a stone than of a wooden house, and less on that lent for the erection of a house, than for carrying on the manufacture of gunpowder. When the whole security rests upon the capital purchased, it is manifest that the risk would, therefore, depend greatly on the nature of the material, and the casualties to which it was subjected.

2. *The character of the borrower.* Men differ greatly in intellectual and moral character. Some, with honest intentions, fail from want of skill; others, with sufficient skill, fail from want of honest intentions. Just in proportion to the deficiency in either of these respects is the risk increased. Every one must see that he would be better off to lend to a skilful and honest man at five per cent., than to a weak or tricky man at ten per cent.

3. The risk depends again upon the *character of the government*. When a government has gained the character of stability, and when justice is administered with promptitude and impartiality, so that every man knows that the whole power of society will be exerted for the purpose of enforcing his rights, the risk will be, by all these circumstances, diminished. When it is otherwise, and when a man knows that the justice of a cause gives no assurance of success, the risk is increased, and interest will, of course, rise. This is one of the causes of the high rate of interest during the period of baronial oppression in Europe.

III. Thirdly, interest will vary according to the *convenience or inconvenience of the investment*.

When a man lends his money, he does not know how soon he may want it again, or how long he may wish to continue it in its present mode of investment. He, also, who lends money, always desires the interest to be paid punctually, because it is by means of this punctuality alone that he is able to make his arrangements for the payment of his own debts. Now, all these circumstances are taken into account by him who has money to lend. He will lend at a lower rate when he can let his property remain lent as long as he pleases, or recall it when he will, and when the interest is paid punctually, than when he is unable to recall it except at a stated time, and may have it returned to him when it is not convenient; and when he cannot rely with certainty upon the punctual payment of the interest.

These several circumstances, as every one must see, enter justly into every transaction in which money is lent. The first is the difference which arises, at different times, from the *productiveness* of capital. This varies continually with the fluctuations in the success of business, and many other causes. Secondly, the rate of interest varies with the risk of the investment, this risk being liable to every degree of variation. And, thirdly, it varies with the convenience or inconvenience of the investment; and all these may be united favourably in one instance, and unfavourably in another.

Hence arises the impolicy and injustice of establishing a legal rate of interest, to which all loans shall be subjected. It is rendering by law a mode of contract *uniform*, which combines within itself more elements of *variation* than almost any other that can be named.

It may be useful, in closing this section, to add a few words respecting the nature of stocks, of which we hear so much in conversation, and see so much in the daily papers.

Suppose a bank is to be established, a railroad, or any other public work to be constructed. The sum which is to be invested is divided into portions, or *shares*, of a given amount; say, for instance, of a hundred pounds each. Whoever wishes to engage in the undertaking, subscribes for as many of these shares as he pleases. When he pays the amount at which the share is valued, he receives a certificate of ownership, which entitles him to all the privileges of a stockholder, the

principal one of which is, that he is entitled to his portion of whatever profit may arise from the operation. These shares are called *stocks*, and are transferable at any moment; the holder, whoever he may be, receiving the interest, or, as it is called, the *dividend*, at the regular times of payment.

The prices of these stocks rise and fall with the rate of interest which the undertaking pays. If any stock purchased at one hundred pounds a-share, pays the regular rate of interest, it will sell for a hundred pounds, and then it is said to be *at par*. If it pay twice the regular rate of interest, and is perfectly safe, it will sell for two hundred pounds a-share, and is then said to be one hundred *per cent. above par*. If it pay but half the regular rate, it will sell for but fifty pounds a-share, and is said to be fifty per cent. *below par*. And so of any other instance.

Stocks, like any other investment, vary in price with the degree of risk to which they are subjected. If a stock pay a high dividend, but yet is liable to be entirely consumed by casualties, it will sell for less than another bearing lower interest, but of which the principal is secure. Thus insurance and steam-boat stocks, though they pay large dividends, never bring a correspondent price, because of the losses to which they are unavoidably exposed. On the contrary, though an investment at present pays but little, yet is expected at some future time to be very valuable, it will bring a high price, on account of the anticipations which are formed concerning it. It is by such circumstances that the rise and fall of stocks are determined. They are constantly for sale in large cities, and their prices will rise and fall with the hopes and fears, the anticipations and apprehensions, of the buyers and sellers.

OF THE PRICE OF LAND, OR RENT.

We have remarked, in the preceding section, that stocks, or any other investments, will bring a price in the market in proportion to the annual interest which may be derived from them. A stock, let it have cost what it may, which produces six pounds a-year, if six per cent. be the regular rate of interest, pays the interest of a hundred pounds, and it will sell for a hundred pounds. If it yield twelve pounds, it will sell for two hundred pounds, and so in any other proportion.

Now, the same remark applies to the rent of land. If an acre of land, after paying the ordinary expenditure for tillage and carrying the produce to market, will yield three pounds profit, it will sell for fifty pounds, supposing the rate of interest to be at six per cent. If the profit that may be derived from it be more, it will sell for more; if less, it will sell for less. And the same principle applies to land, whether it be used for tillage or for dwelling-houses.

Such is the general principle on which the rent of land depends. It is, however, to be remembered, that the productiveness of land depends upon two circumstances, *fertility* and *situation*.

1. *Fertility*.—Every one knows that there exists great difference in the fertility of land. With the same cultivation, an acre, in some situations, will yield twice or three times as large a harvest as an acre in other situations. Some lands require annual manuring, others never need to be manured at all. Now, inasmuch as from an acre in the one place, you can derive three times as much income as from an acre in the other, it is reasonable to suppose that the former would sell for three times as much as the latter.

2. *Situation*.—The products of land, however, are bulky, and it costs a very considerable portion of their exchangeable value to transport them to the market. The price of transportation is always to be deducted from the farmer's profit, and tends, by so much, to reduce the value of his land. It is on this account that railroads, canals, and other means of internal improvement, confer so great a benefit upon a country. They remove the disadvantages of situation by reducing the cost of transportation.

Bearing these principles in mind, it will be easy to

perceive in what manner rents will be adjusted in any given country. When a territory is at first settled, the land may be had for nothing. Every one being at liberty to choose for himself, the most productive lands, that is, the most fertile and those most favourably situated, will be at first selected. These will bear no price and will yield no rent, because they may be had for nothing.

When, however, these are all occupied, and others are needed, the land of the next inferior fertility will be put under tillage. As soon as this is done, the first class of lands will yield rent, and will command a price. Suppose lands of the first class to have produced fifty bushels to the acre, and lands of the second class but forty bushels. It will be as cheap for the settler to hire a farm of the first class, at a rent of ten bushels to the acre, as to have a farm of forty bushels to the acre for nothing. When the lands of the second class are all occupied, those of the third class will come into request; and as soon as these are tilled, those of the second class will also command a price and will produce a rent. At the same time, the price and the rent of lands of the first class will be doubled. In this manner, the rise of price and of rent in lands of various grades of fertility will go on increasing, until all the land worthy of cultivation is occupied.

As the common market for agricultural products is on the sea-coast, it might be supposed that the price of land would gradually diminish as you remove into the interior, until its disadvantages of situation reduced its value to nothing. This would be the case were it not for various counteracting circumstances. Among these are the following:—

1. The fertility of land, in many instances, increases as we retire from the coast. This fertility counterbalances the disadvantages of situation.

2. As a country advances in civilisation, its means of internal communication improve, and the inconvenience of situation is more and more removed.

3. As a country becomes settled, towns and cities grow up in the interior, and thus bring a market to the farmer. He is as much benefited by the bringing of the market to him, as he would be by the removal of his land to the market.

4. Sometimes a new invention in the arts transforms at once the conditions on which the progress of a country depend. Such was the result of the introduction of steam navigation on the waters of the Mississippi and its tributary streams. This invention opened this whole valley to the Atlantic, and gave to the towns on the banks of the river almost the advantages of a position on the sea-coast.

Besides these general circumstances, on which the price of land depends, some others may be mentioned which are well worthy of notice. Man is endowed with a love for the beautiful, as well as with an intellectual and moral nature, and he very commonly takes these tastes into account in choosing for himself a place of abode. Hence, land which is handsomely laid out and tastefully arranged, whether in a village or in the country, will sell for a higher price than that which possesses none of these recommendations. A farm or a dwelling-house, in a well-cultivated neighbourhood, where the people are virtuous and benevolent, will find more purchasers, and of course will sell for a higher price, than one of equal fertility where the inhabitants are ignorant and vicious, quarrelsome and malicious. Hence we see that were men to consult nothing but their own interests, they might very reasonably devote more care than they commonly do to embellishing their grounds and supplying themselves and their families with the means of intellectual and moral improvement.

Land, however, is not always used for the purposes of agriculture. It is used in cities and towns, merely to afford space for the erection of storehouses and dwellings. In this case, of course, its fertility is of no consequence, and its only value depends upon its situation. Hence, its price will be determined merely by this circumstance. Those portions which afford the

greatest facilities for business, will command the highest rent; and those which recede from them will command a lower and lower rent, until they have receded so far from the centre of business, that the land is only valuable for dwelling-houses. The value of these again gradually diminishes, until situation is but a small part of the price, and the land may profitably be devoted to gardening. Here the element of fertility again enters into the computation. The land immediately around a large city, is thus commonly occupied by those who supply the market with recent vegetables and milk. At a small distance beyond, it is devoted to the general purposes of agriculture, and becomes what may be properly denominated the country.

Having thus considered the general principles upon which the distribution of the profits of any undertaking is effected, we shall close this section by an example illustrating the manner in which these principles operate in an individual instance.

We will take, for the sake of this illustration, a loaf of bread. A farmer in the West Riding of Yorkshire devotes his land to the raising of wheat. He tills his land, raises his crop, and sells it to the miller. The price which he receives for his crop repays him for the cost of his own labour, the wages and support of his workmen, the cost of manures, the rent of his land, and interest on all the capital which has been invested. If he owe the land, he receives the rent himself; if he hire it, he pays it to the landlord. The miller receives the grain, manufactures it into flour, transports it to Hull, and sells it to the flour-merchant. The sum for which he sells it, repays him whatever he had paid the farmer, and remunerates him for the cost of making the flour. This must be sufficient to enable him to pay his various workmen, to remunerate him for his own labour and skill, the use of his capital, the wear and tear of his mill, and the cost of transportation to Hull. What he has paid the transportation agent must be sufficient to remunerate him for the use of his canal boats, the men and horses that have been employed in navigating them, the expense of tolls, and the interest on all the capital which is employed in the operation. The flour-merchant buys the flour, and keeps it in his storehouse to supply his customers. He is entitled to a sum sufficient to repay him for what he paid the miller, and also to interest on his investment, to remuneration for his labour and skill, and the cost of store-room. The baker purchases the flour of the flour-merchant, and makes it into bread. He charges for his bread sufficient to repay him for what he paid the flour-merchant, and for all his labour and expense in turning the flour into bread. Thus, when we purchase a loaf of bread, we pay our proportion of all these several expenses. And these several amounts, in all these instances, are distributed according to the rules which we have laid down. All the labour which has been employed is paid according to its value and skill; and all the capital according to the use and risk to which it had been subjected. The various items of cost, in the production of any article of use, may be easily analysed in a similar manner.

CONSUMPTION.

OF THE NATURE AND DESIGN OF CONSUMPTION.

We have thus far endeavoured to show in what manner the various objects for the gratification of desire are *produced*, in what manner they are *exchanged* among the producers, and in what manner the share to which each one of the producers is entitled, is *distributed* to each of them.

But we know that all this is done with reference to another object. Every thing that is of any value is designed to be used, and after it is thoroughly used, or, in familiar language, *used up*, it is worthless. All these previous operations only prepare the way for *consumption*, and it is consumption that creates the necessity for their being incessantly repeated.

Consumption is the reverse of production. Production is the act by which we *confer* value. Consumption is the act by which we *destroy* the value which has been thus conferred. When we speak of the destruction of value, we do not mean that the material itself is destroyed, but only that the form in which a particular value resided has been changed, and that hence that particular kind of value is annihilated. Thus, if a load of wood be burned, its power of creating heat is destroyed for ever. If bread be eaten, or thrown into the sea, or burned by accident, or rendered useless by mould, in either case its utility is destroyed, and we say the bread is consumed. And thus we see that it makes no difference, as to the *fact* of consumption, whether any benefit be *derived* from it or not. In the one case as well as in the other, the utility is destroyed.

It seems to be a law of nature, that we cannot create one value without destroying another. He who chops down a tree and saws it into boards, destroys for ever the value of the tree as a tree. It can never more give shade to the traveller nor gratify the taste of the tourist. He who butchers an ox for beef destroys for ever the utility of the animal as a beast of draught. If we eat an apple, we annihilate for ever the quality in the apple of giving pleasure to any other being. And thus, in general, consumption is a sort of exchange, in which we surrender one value for the sake either of creating another value, or else for the sake of gratifying some desire, which we consider of more importance than the existence of the value which we annihilate.

1. Consumption is either of *labour* or of *capital*. If I purchase five dollars' worth of mahogany and pay a mechanic ten dollars for his *labour* in making it into a table, I have consumed five dollars' worth of capital and ten dollars' worth of labour. If I have made it myself, instead of employing another, I have consumed the same amount of value in my own labour. And, inasmuch as it costs just as much to support a human being whether he labour or whether he remain idle, the spending a day in idleness should always be considered as the consumption of a day's labour. In estimating the benefit of holidays, we should always remember that the time which they occupy is the consumption of so much labour. And the profitableness of the consumption is to be estimated by the benefit of the result which is attained.

2. Consumption is either *partial* or *total*. Sometimes, after one value has been consumed, another and an important value remains. A pair of India-rubber shoes may be worn out, and be useless as shoes, and yet they may be valuable for the manufacture of India-rubber cloth. A linen garment may be worn out, and its utility as a garment may have been annihilated, and yet it may possess an important value to the paper-maker. On the other hand, when we eat a piece of bread, as it has but one value, and that value is destroyed, the consumption is total. When we burn gunpowder in fireworks, and, commonly, when we use property to gratify our appetites, the case is the same. Hence we see the importance of consuming every value of every kind which a substance possesses; and also of consuming nothing for the purposes of gratification, unless for a reasonable and adequate cause.

3. Consumption is either *voluntary* or *involuntary*. It is voluntary when we destroy value by design, for the purpose of accomplishing some ulterior result. It is involuntary when it takes place by accident. A pile of wood may be burned in a fire-place for the purpose of warming a parlour, or, on the other hand, it may be set on fire by accident and totally consumed. In the one case, as in the other, the value is destroyed, the only difference is in the result.

Besides, however, the consumption by accident, a continual consumption is going on by the ordinary agents of nature. If a pile of wood is suffered to remain for a long time exposed to the changes of the weather, it will be rendered utterly worthless. Its value is thus as entirely destroyed as it would have been by fire. If

a loaf of bread become mouldy through neglect, its value is as thoroughly consumed as if it had fallen into the fire the moment after it had been baked. Vegetable matter decays—animal matter putrefies—the metals are corroded; and thus consumption is continually going on, by which the values which we create will be destroyed, unless we watch over them with perpetual vigilance. Childish, imbecile carelessness is enough to render any man poor, without the aid of a single positive vice.

4. Consumption is either *rapid* or *gradual*. The consumption of wood for fuel is rapid. The consumption of the axe with which we chop it, or of the fire-place in which we burn it, is gradual. But the one is going on as certainly as the other; and hence, in estimating his expenses, if a man wish to estimate them correctly, the one must be taken into the account as well as the other. If a man build a house and occupy it for ten years, the gradual consumption has materially diminished its value. If, now, at the close of this period, he estimate the value of the house at its original cost, he will greatly overrate his property. The same is true of furniture, and of every thing else which we use.

It need scarcely be remarked, that the annual consumption of an individual is the total amount of values which he consumes, whether in his business or in his family. Unless his annual production be sufficient to replace the whole of his annual consumption, he will run in debt. By as much as his annual production exceeds his annual consumption, he will be growing richer. Hence, the object of every thrifty man is to render this excess as great as possible.

II. Of the Design of Consumption.

The design of consumption is easily seen. Inasmuch as consumption is the destruction of some value, it is of the nature of an infelicity. We never therefore consume, but with the expectation of procuring some greater good than that which we annihilate. This good may be of two kinds. First, we consume one value for the sake of procuring another and better value; or, secondly, we consume a value for the sake of gratifying some appetite or desire, that is, for the sake of increasing our own personal happiness.

1. *Consumption for the sake of the increase of value.*—In this manner the farmer consumes seed, manures, labour, and tools, that he may thus be enabled to produce a harvest. The manufacturer consumes raw cotton, labour, machinery, &c., in order to produce cloth. The mantua-maker consumes calico, thread, needles, and labour, in order to produce a new dress. And thus, in all the various occupations of men, materials of every kind, and labour, are consumed for the sake of creating some article of use, or convenience, or luxury.

2. *Consumption for the sake of the gratification of desire.*—Some of our desires have respect to our life, and health, and comfort. Such are the desire for food, clothing, shelter, and the various conveniences by which the heat of summer and the cold of winter may be modified. Others are merely for the gratification of the senses, without any regard to the benefit which we derive beyond that of simple sensual pleasure. Such are the desires for the luxuries of the table, of dress, equipage, and for those modes of living which are demanded by fashion. Some of our desires are gratified by intellectual pleasures, and others by the pleasure of doing good. It is not necessary that I should enumerate all the various modes of expenditure. In general they consume the value which they appropriate, and all that remains is the gratification which they produce.

OF THE DIFFERENT KINDS OF CONSUMPTION.

Consumption is of two kinds, *individual* and *national*. Individual consumption is of two kinds, first, for the sake of *reproduction*, and secondly, for *gratification*.

Of Individual Consumption for the sake of Reproduction.

The design of the consumer in this case is the reproduction of capital, in some form different from that

in which the capital is consumed. He would gladly produce without consumption, were it possible. But to do so is contrary to the law of his being. Consumption is necessary; but if a man be wise, he will consume as little as possible. Production is his remuneration, and if he be wise, he will render this as great as possible. His whole gain is the amount by which his production exceeds his consumption. The greater this excess, the greater will be his profit. The rule by which he should therefore be governed, is to create as large a product as possible, by the consumption of as small a value as possible.

The consumption of a producer is of two kinds—of capital and of labour.

Of Consumption of Capital.—The principles which should govern us here, are, I suppose, the following:—

1. The consumption of capital should be as small in amount as is consistent with the creation of the desired product. A shoemaker, who habitually cuts up a side of leather so carelessly that leather sufficient for one pair of shoes is wasted, will never grow rich. The farmer who sows two bushels of seed when one would have answered as well, loses the half of his seed. In China, sowing is always done by drilling instead of broadcast. It has been computed that, by this method, as much grain is saved as would feed the whole population of Great Britain. The useless expenditure of fuel in Britain is enormous. It is supposed, and with good reason, that not more than one-tenth of the heat of the fuel employed is rendered available in a common fire-place.

2. Capital of no greater value than is necessary should be employed to create the desired product. Thus, it is for the interest of every producer to ascertain in what manner he may be able to accomplish his purpose, by the consumption of the least valuable materials. The merchant inquires before he imports a product from a foreign country, with what export he can procure it at the cheapest rate. So the manufacturer, if he be wise, will keep himself informed of the progress of science and of the arts, that he may learn in what manner a cheaper article may be substituted for a dearer in the creation of his product. A fortune has frequently been realised by the discovery of a cheaper dye-stuff, or the substitution of a single cheaper material in the place of that ordinarily in use.

3. Every utility possessed by the material consumed should be rendered in the best manner available. Thus in an oil-mill the flax-seed from which linseed oil has been expressed is a valuable food for cattle. After the brewer has extracted the saccharine matter from barley, the grains, as they are called, are valuable for the same purpose. The tan bark, after the tanning matter has been extracted, is valuable for fuel. This economy of materials is very well illustrated in the manufacture of combs. In a well-conducted establishment of this kind, every part of the horn, the core, the body, the tip, the shavings, the fat, and the mucilage, are all turned to some available purpose.

Nor is this all. The values which are consumed should be consumed to the very last. Thus, in the working of a steam-engine it is necessary to evolve a great amount of caloric, and this is the most expensive part of the process. Now, economy demands that this caloric should be produced at the least possible expense, and that having been produced it should be used for every purpose that it can be made to serve. But every one must have perceived, by the flame which escapes from the chimney of a furnace, that a very large portion of the caloric evolved is absolutely wasted. A very great economical improvement has of late been made in some of the iron-works in Great Britain. This caloric, which was formerly wasted, is used to heat the air which is blown into the furnace. By this expedient a very great saving of fuel is accomplished.

Consumption of Labour.—As labour is expensive in the same manner as capital, economy teaches us to consume precisely as much of it as is necessary to accomplish our purpose in the best possible manner.

1. We should employ no more labour than is necessary. Too many labourers will always encourage each other in idleness. When there is one man at leisure to tell stories, the time of several others must be consumed in listening to them.

2. We should employ no less labour than is necessary. When, from want of a sufficient number of labourers, one labourer is obliged to perform several kinds of work, we lose the advantage of division of labour, and also expose ourselves to all the inconveniences of confusion and disorder.

3. We should employ labour of no higher price than is necessary.

In any extensive operation it will be seen upon reflection that some parts of the process require more skill and attention than others. Some will require labour worth five or ten shillings a-day, and others labour worth not more than eightpence or one shilling a-day. It is of great importance in any large establishment so to arrange the labourers that no workman shall be employed at a higher price than the labour which he performs is actually worth. It is, however, to be remarked, that an error may exist of the opposite kind. It is as bad economy to employ too cheap as too dear labour. In the one case, we lose by paying too high a price for labour, in the other, by that destruction of materials, which always results from the want of skill in a labourer.

4. The labour which we have paid for should all be performed. Time is money, to him at least who pays money for it. If it be wasted, his money is thrown away; and by throwing away money no one ever became rich.

In order to secure this result, several things must, however, be attended to. The most important of these is, that he who employs labourers should in person superintend his own affairs. No one will take as much interest in our own concerns as ourselves. When this cannot be done, the establishment should be so arranged as to ensure full and vigilant superintendence over every part, and under such responsibilities as will bring a knowledge of any delinquency to the notice of the competent authority.

Besides this, much time is saved by system and regularity. When one is obliged to wait for another, much labour is of necessity wasted. Tools should always be in the best possible condition. This saves time, and takes away one of the most common excuses for negligence.

Consumption for Gratification.

Consumption may be conducted upon economical principles, or the reverse. It is clearly the interest of every individual that he should not consume his capital by expenditure upon objects which are to yield him no pleasure or profit of any kind; that every thing he purchases should be consumed as thoroughly as possible, and not in any respect wasted. In this way no labour is lost. It is the same with national consumption or expenditure. When the public money is spent upon war, upon idle functionaries or sinecurists, or upon any kind of public work which is not to be either directly or indirectly useful, the labour which produced that money is lost, or has gone in vain. It is nothing in such cases to say that money has been circulated, that employment has been given, and so forth. Men do not absolutely need to be kept working in any particular way, and every idle consumer of others' goods than his own is a source of loss to the community. The labour could have been applied otherwise, and to a useful instead of a useless end.*

* We have to acknowledge ourselves indebted for the above sketch of the science of Political Economy to an American writer. It is abridged, with a few slight alterations, from a small work entitled "The Elements of Political Economy, by Francis Wayland, D.D., President of Brown University." Boston, U. S. 1837.

POPULATION—POOR-LAWS—LIFE-ASSURANCE.

POPULATION.

THE rate at which human beings naturally increase, the proportion which this increase bears to the means which exist for their subsistence, and the laws which operate to bring the increase and the means of subsistence into conformity, were subjects scarcely reflected on by our ancestors, but have been matter of keen controversy during the first thirty years of the present century.

As far as population was at all thought of in former times, the prevalent doctrine was, that the greater the numbers of a nation, the stronger was the state, and the more likely was that country to be a scene of both agricultural and commercial industry. So useful were numbers considered for increasing the means of subsistence and also of national defence, that in many countries it was thought proper to make laws for encouraging matrimony, and to put bounties on all families exceeding a certain number. So lately as the time of Louis XIV., pensions were given in France to individuals who had ten or more children.

Dr Adam Smith, in his *Wealth of Nations*, was perhaps the first to suggest any thing like a law as regulating the increase of population. He remarked, that "the demand for *men*, like that for any other commodity, necessarily regulates the production of men; quickens it when it goes on too slowly, and stops it when it advances too fast. It is this demand," says he, "which regulates and determines the state of population in all the different countries of the world—in North America, in Europe, and in China; which renders it rapidly progressive in the first, slow and gradual in the second, and altogether stationary in the last."

VIEWS OF MR MALTHUS.

This hint, for it is little else, is said to have been what suggested the celebrated essay of Mr Malthus, which first appeared in 1798, but was almost reconstructed in a second edition of 1803. There was something so startling in the views of this writer, and at the same time so much plausibility in his arguments, distressing as they were to natural feelings, that his work attracted great attention, and many of the ablest thinkers and writers of the day became converts to its main doctrines.

An abridgment of Mr Malthus's views, given in the *Edinburgh Review* for August 1810, sets out by showing that "the rate of population is by no means the same in all parts of the world." The variations in the rate are universally preceded and accompanied by variations in the means of maintaining labourers. "Where these funds are rapidly increasing, as in North America, the demand for an increasing number of labourers makes it easy to provide an ample subsistence for each; and the population of the country is observed to make rapid advances. When these funds increase only at a moderate rate, as in most of the countries of Europe, then the

demand for labourers is moderate; the command of the labourer over the means of subsistence is consequently much diminished; and the population is observed to proceed with a moderate pace, varying in each country, as nearly as may be, according to the variations in the funds for its support. Where these funds are stationary, as we are taught to believe is the case in China, and as has certainly been the case in Spain, Italy, and probably most of the countries of Europe during certain periods of their history, there the demand for labour being stationary, the command of the labourer over the means of subsistence is comparatively very scanty, and population is observed to make no perceptible progress, and sometimes to be even diminished.

In the second place, it is a fact equally notorious, that the actual increase of the funds for the maintenance of labour does not depend simply upon the physical capacity of any particular country to produce food and other necessities, but upon the degree of industry, intelligence, and activity, with which these powers are at any particular time called forth. We observe countries, possessing every requisite for producing the necessities and conveniences of life in abundance, sunk in a state of ignorance and indolence, from the vices of their governments, or the unfortunate constitution of their society, and slumbering on for ages with scarcely any increase in the means of subsistence, till some fortunate event introduces a better order of things; and then the industry of the nation being roused and allowed to exert itself with more freedom, more ample funds for the maintenance of labour are immediately provided, and population is observed to make a sudden start forwards, at a rate quite different from that at which it had before proceeded.

This seems to have been the case with many of the countries of Europe during some periods of their history; but is more particularly remarkable in Russia, the population of which, though very early inhabited, was so extremely low before the beginning of the last century, and has proceeded with such rapid steps since, particularly since the reign of Catherine II.

It is also a fact that has often attracted observation in a review of the history of different nations, that the waste of people occasioned by the great plagues, famines, and other devastations to which the human race has been occasionally subject, has been repaired in a much shorter time than it would have been, if the population, after these devastations, had only proceeded at the same rate as before. From which it is apparent, that after the void thus occasioned, it must have increased much faster than usual; and the greater abundance of the funds for the maintenance of labour, which would be left to the survivors under such circumstances, indicates again the usual conjunction of a rapid increase of population with a rapid increase of the funds for its maintenance. Just after the great pestilence in the time of Edward III., a day's labour would purchase a

bushel of wheat ; while, immediately before, it would hardly have purchased a peck.

With regard to the minor variations in the different countries of Europe, it is an old and familiar observation, that, wherever any new channels of industry and new sources of wealth are opened, so as to provide the means of supporting an additional number of labourers, there, almost immediately, a stimulus is given to the population ; and it proceeds for a time with a vigour and celerity proportionate to the greatness and duration of the funds on which alone it can subsist."

From these and other premises, Mr Malthus laid it down as a proved fact, that population tends to increase at the rate of a doubling every twenty-five years. He, at the same time, endeavoured to show that, as man begins to use the best lands first, and then has to go to worse and worse, it becomes always more and more difficult to obtain the means of subsistence for increasing numbers. He concluded that, at the utmost, the means of subsistence would be found, at the end of each successive quarter of a century, to have increased only at the rate of double for the first, triple for the second, quadruple for the third, and so on. Thus (said he) while population would go on increasing in a geometrical ratio, that is, as 1, 2, 4, 8, 16, 32, 64, 128, &c., food would increase only in an arithmetical ratio, that is, as 1, 2, 3, 4, 5, 6, 7, 8, &c. ; and the consequence of an unchecked increase of the one, with the utmost possible increase of the other, would be that, when the population of the globe had advanced to 500,000 millions, there would only be food for 10,000 millions, or a fiftieth part of the number !

Considering, then, that there is a power and a tendency in human beings to increase so rapidly, and that, in point of fact, it is only in a few favoured spots that they do increase at such a rate, Mr Malthus concluded that there must be some counteracting agencies, or *checks*, in constant operation, in almost all communities, to restrain population at a lower rate of increase, or keep it stationary. In looking about to discover these checks, he satisfied himself that they were of two orders : first, there was the mortality produced by the effects of deficient food and of wicked passions ; these he called *positive checks* : then there was the check produced by a prudent forethought in human beings, leading them to avoid marriage, on account of the little prospect of being able to rear a family in comfort ; this he called the *preventive check*.

Arriving at this point, Mr Malthus and his followers proceeded to show how their doctrines were applicable for the benefit of communities. It was held that there could be no choice between the two kinds of checks : it was clearly preferable that population should be restrained by the preventive check.

"It is observed," says the *Edinburgh Review*, "in most countries, that in years of scarcity and dearth, the marriages are fewer than usual ; and if, under all the great variations to which the increase of the means of subsistence is necessarily exposed from a variety of causes—from a plenty or scarcity of land, from a good or a bad government, from the general prevalence of intelligence and industry or of ignorance and indolence, from the opening of new channels of commerce or the closing of old ones, &c. &c.—the population were proportioned to the actual means of subsistence, more by the prudence of the labouring classes in delaying marriage than by the misery which produces premature mortality among their children, it can hardly be doubted that the happiness of the mass of mankind would be decidedly improved.

It is further certain, that, under a given increase of the funds for the maintenance of labour, it is physically impossible to give to each labourer a larger share of these funds, or materially to improve his condition, without some increase of the preventive check ; and, consequently, that all efforts to improve the condition of the poor, that have no tendency to produce a more favourable proportion between the means of subsistence and the population which is to consume them, can only be

partial or temporary, and must ultimately defeat their own object.

It follows, therefore, as a natural and necessary conclusion, that in order to improve the condition of the lower classes of society, to make them suffer less under any diminution of the funds for the maintenance of labour, and enjoy more under any actual state of these funds, it should be the great business to discourage helpless and improvident habits, and to raise them as much as possible to the condition of beings who 'look before and after.' The causes which principally tend to foster helpless, indolent, and improvident habits among the lower classes of society, seem to be despotism and ignorance, and every plan of conduct towards them which increases their dependence and weakens the motives to personal exertion. The causes, again, which principally tend to promote habits of industry and prudence, seem to be good government and good education, and every circumstance which tends to increase their independence and respectability. Wherever the registers of a country, under no particular disadvantages of situation, indicate a great mortality, and the general prevalence of the check arising from disease and death over the check arising from prudential habits, there we almost invariably find the people debased by oppression and sunk in ignorance and indolence. Wherever, on the contrary, in a country without peculiar advantages of situation, or peculiar capability of increase, the registers indicate a small mortality, and the prevalence of the check from prudential habits above that from premature mortality, there we as constantly find security of property established, and some degree of intelligence and knowledge, with a taste for cleanliness and comforts, pretty generally diffused.

Nor does experience seem to justify the fears of those who think, that one vice at least will increase in proportion to the increase of the preventive check to population. Norway, Switzerland, England, and Scotland, which are most distinguished for the smallness of their mortality, and the operation of the prudential restraint on marriage, may be compared to advantage with other countries, not only with regard to the general moral worth and respectability of their inhabitants, but with regard to the virtues which relate to the intercourse of the sexes. We cannot, as Mr Malthus observes, estimate with tolerable accuracy the degree in which chastity in the single state prevails. Our general conclusions must be founded on general results ; and these are clearly in our favour.

We appear, therefore, to be all along borne out by experience and observation, both in our premises and conclusions. From what we see and know, indeed, we cannot rationally expect that the passions of man will ever be so completely subjected to his reason, as to enable him to avoid all the moral and physical evils which depend upon his own conduct. But this is merely saying, that perfect virtue is not to be expected on earth ; an assertion by no means new, or peculiarly applicable to the present discussion. The differences observable in different nations, in the pressure of the evils resulting from the tendency of the human race to increase faster than the means of subsistence, entitle us fairly to conclude, that those which are in the best state are still susceptible of considerable improvement, and that the worst may at least be made equal to the best. This is surely sufficient both to animate and to direct our exertions in the cause of human happiness ; and the direction which our efforts will receive, from thus turning our attention to the laws that relate to the increase and decrease of mankind, and seeing their effects exemplified in the state of the different nations around us, will not be into any new and suspicious path, but into the plain beaten track of morality. It will be our duty to exert ourselves to procure the establishment of just and equal laws, which protect and give respectability to the lowest subject, and secure to each member of the community the fruits of his industry ; to extend the benefits of education as widely as possible, that, to

the long list of errors from passion, may not be added the still longer list of errors from ignorance; and, in general, to discourage indolence, improvidence, and a blind indulgence of appetite without regard to consequences; and to encourage industry, prudence, and the subjection of the passions to the dictates of reason. The only change, if change it can be called, which the study of the laws of population can make in our duties, is, that it will lead us to apply, more steadily than we have hitherto done, the great rules of morality to the case of marriage, and the direction of our charity; but the rules themselves, and the foundations on which they rest, of course remain exactly where they were before."

This must be considered as the mildest possible exposition of the application of Mr Malthus's doctrines: his theory almost necessarily led to some other practical inferences, of a kind to which it is not so easy for a humane mind to assent. It came to be held, for instance, that, where the preventive check had not operated, it was quite legitimate to allow the positive to come into operation. A human being, who had come into existence undemanded by the state of the funds for subsistence, was to be told that the places at Nature's table were all occupied, and there was no cover for him. To the man who married when there was a redundancy of population, "all parish assistance," said Mr Malthus, "should be most rigidly denied; and if the hand of private charity be stretched forth in his relief, the interests of humanity imperiously require that it should be administered very sparingly." These notions were adopted very generally by a class of political economists, and for twenty years they were in vogue in England, where the notorious abuses of the old poor-law had prepared the minds of many for taking extreme views with regard to public charity. But it was impossible for the great bulk of the community to give a cordial reception to doctrines so violently in opposition to the dictates of the natural feelings.

OBJECTIONS TO MR MALTHUS'S VIEWS.

A reaction at length took place against the Malthusian theory, and opposite views were presented by various writers, the most distinguished of whom was Mr M. T. Sadler, whose work, entitled *The Law of Population*, appeared in 1830.

By these writers it was represented, that, in America and the Australian colonies, there was an evident tendency in subsistence to increase in a more rapid ratio than population, inasmuch that flocks and herds became a drug, and it was not uncommon in Brazil to use fat carcasses of mutton as fuel in lime-kilns. The only difficulty experienced in those regions was in obtaining a market for the vast amount of produce not needed by the native population. Here, it was said, is a clear case in disproof of the proposition that population always tends to increase more rapidly than food.

As for the geometric ratio of the human increase, by which so great an alarm had been excited, what was it, after all, but a different form of the obvious truth, that the more people there were, there would be the more parents, and consequently the more children? Suppose ten families, existing in 1800, having become twenty in 1825, it might certainly be expected that the addition between the last date and 1850 would be other twenty, not ten merely, seeing that the start was not from ten, as it had been before, but from twenty. Such is but an unavoidable consequence of population swelling by multiplication and not by addition. But if the human family follows this ratio of increase, so do all the orders of organic beings, animal and vegetable; sheep, oxen, and hogs, increase at the geometric ratio as well as mankind, and what is more, they begin to multiply at a much earlier period of life. Poultry, for instance, could probably multiply themselves a million of times, before a couple of the human race could do so once. The vegetable food of man is capable of a still more rapid increase. Wheat generally returns from ten to twenty fold in one year. The produce of a single acre of this grain, increased year after year in the ordinary

way, would require only fourteen years to reach an amount which would occupy the whole cultivable surface of the globe. And as it is with wheat, so is it with most of the other plants on which we depend for food, either for ourselves or for the animals which become food to us. So that, instead of there being any such disagreement between the natural possibilities of increase in human beings and subsistence, as Mr Malthus insisted on, there would appear to be a discrepancy in exactly the contrary way; that is to say, subsistence appears to be capable of a much more rapid increase than human beings.

But—the Malthusians object—when the best soils are all under cultivation, it is necessary to resort to the inferior. These require more labour and afford less return. There is therefore a *decreasing fertility* in the country, while its population is always increasing. To this it is replied by the opposite party, that, while worse and worse soils are in the course of being resorted to, better and better modes of culture are coming into operation, so as to make, perhaps, a third-rate soil capable of producing as much, by a certain amount of labour, as a second-rate soil was a few years before, and so on with the other qualities, each being raised a degree in the scale by every fresh effort of human ingenuity. In point of fact, the best British soils do now bear four times the quantity of grain which they did a few centuries ago, and millions of acres then deemed unfit for tillage now produce as much by the same degree of labour as the best soils did at that time. Perhaps the answer is less satisfactory on this point than on any of the rest.

The Malthusians, however, were said by their opponents to derive the strength of their case from limiting their views to a certain region. Their propositions, it was admitted, might be true with regard to a population shut up in a certain small space, without any connexion with what was beyond. But such a population never existed, and therefore the apprehended evils never could take place. From the earliest notices we have of the human family, it appears to have been their custom to spread abroad over the soil, when they found that food could be more easily obtained at a distance from the natal spot than at the natal spot itself. The original command given to man, *to increase, and multiply, and replenish the earth*, is only in accordance with what has always appeared as a tendency of the race. It is probable that, at the present time, not above one-hundredth part of the earth's surface is cultivated, and not one-hundredth part of that cultivated in a scientific or advantageous manner; while, from what has taken place, we may reasonably calculate upon the productiveness of the best cultivated parts being yet greatly increased. With such an almost indefinite field still before us, it seems absurd to be under any anxiety as to the supposed tendency of the human family to a too rapid increase. The superabundance of one district has only to go to some yet unpeopled spot, or to exert ingenuity and industry to raise more food from that which they do occupy, in order to maintain themselves in comfort. There is another means whereby it may chance that a superabundant population can support itself in the native locality, though the productiveness of that locality falls short of the demand for food. If it possess advantages for manufactures, it can exert its industry in that way, and exchange the products for food raised in other countries, where subsistence exceeds population, and advantages for manufactures do not exist.

The opponents of Mr Malthus combated his notion of checks on moral and religious grounds; and here, certainly, the natural feelings of mankind greatly favoured their views. It was held as an impeachment of that system of wisdom and benevolence seen throughout all nature, that one of the most powerful tendencies of human beings should be supposed to require being put under an absolute arrestment, upon the penalty of its otherwise leading to misery in the individual and embarrassment in the community. It was held that the preventive

check, supposing it to be capable of operating without an increase of immorality, was necessarily attended by an abridgment of human happiness, in as far as it involved a denial and repression of the domestic affections. Its cruelty was also partial, for it bore solely on the poorer classes, to whom celibacy is a greater hardship than to the rich. And even supposing that it could be morally carried into effect, so as to keep down population at a certain level, it was, after all, an uncalculated for interference with divine arrangements, which, from all analogy, as well as from their practical effect, might be supposed as having been designed for good ends. For do we not see that the charge of a family acts in all well-constituted minds as an incentive to industry? and can we doubt that equally with a growing population tend, in ordinary circumstances, to increase the industry of a nation? Contemplated thus, the tendency to increase would appear as a means, in Providence, to stimulate men and nations to the utmost possible exertions for the improvement of the materials placed at their command, so that no faculty of their being might lie waste, and no power of physical nature remain useless. Supposing this to be one of the final causes of the population principle, the preventive check of the Malthusians must, of course, appear as an impious attempt to control one of the Creator's most important designs.

OBSERVATIONS.

Such is an outline of the arguments which have been used on this famous question. It must, we think, be generally evident to new and dispassionate inquirers, that there is some truth in the views of both parties, but that the full and exact truth has not been stated by either. For arriving at this the means do not perhaps exist in the present imperfect state of statistical science; but in the mean time we may present a few considerations which have occurred to ourselves on this subject.

It appears to us to be only an assumption that there is every where a tendency to double the population every twenty-five years. We certainly see that such is the case in North America; but possibly this is considerably owing to temptations which are presented by the state of the country, labour being so expensive in all such regions, that a bounty may be said to be put upon the possession of a family. Perhaps the natural tendency is there drawn into something approaching to an unnatural state of activity.

Allowing that the increase is no more than what the natural inclinations of that people dictate, it is by no means clear that all nations possess natural inclinations in the same degree. We know that many features of human character are manifested in very different degrees in different nations; and it is therefore not unreasonable to suppose that there are also national differences in those feelings which lead to the increase of the human family. Individuals, it is well known, are characterised very differently in this respect. There are also obvious differences in families, the peculiarity being apparently hereditary. Why, then, may there not be differences also in nations? Perhaps the light to be derived from the history of families and of individuals, has not yet been taken sufficient advantage of for the illustration of this question. A careful inquiry would probably show a far greater amount of natural causes for the obstruction of population, and these altogether independent of Mr Malthus's checks, than philosophers are at all prepared for.

The history of many families of historical note uncontestedly shows, that often, with all external advantages, there is surprisingly little tendency to increase. The extinct peerage and baronetage of England forms, it will be recollected, a pretty large book. In that high rank, there is greater longevity, and consequently, it may be presumed, better health, than in lower grades; yet the line often fails for lack of heirs. To take a few cases which happen to be familiar to us—When George fifth Duke of Gordon died a few years ago, it was

necessary, in order to get an heir for one of his titles destined to heirs-male, to go back to the ancestor who had flourished in the time of the civil war, all the intermediate persons having failed to send down male heirs, though many had had several sons born to them. When the main line of the Keith Mareschal family became extinct in 1778, it was necessary to go back for a male representative to a collateral line which sprang off from the main one at the end of the fifteenth century, although many goodly representatives and male cadets had flourished in the interval. It is well known that no representative of the royal family of Stuart since Robert III., who died in 1406, has at this time legitimate male descendants. In short, it would appear that families may exist in flourishing circumstances for hundreds of years, and after all, the male progeny may become extinct, and the name of the race be in time looked for in vain. The contrary is, no doubt, often true: for example, the male progeny of the above-mentioned Scottish king exist in great numbers, in all conditions of life. But, while it is the lot of some to be thus multiplied exceedingly, it is not less true that many leave not one copy of themselves, and that even whole clans, numerous at one time, will ultimately shrink, like an exhaled river, and disappear from the land, and all this notwithstanding an apparent sufficiency of what is necessary to comfortable existence. An illustration occurs to us, to which, we believe, many of our readers will readily find parallels within their own knowledge. A citizen of Edinburgh, who died about thirty years ago, had seventeen sons and daughters, most of whom reached maturity. All the members of this second generation have ever since been in comfortable circumstances: some are now dead; the rest have passed on to such periods of life that it is not to be expected that children will hereafter be born to any of them. And what is the number of the third generation of this family? Only *eight*, the offspring of two marriages. Thus showing that the progeny of a single pair may look large at the first remove, but shrink at the second. We may add, that this family appears decidedly marked by much less than the average of a tendency to matrimonial life. As facts are what is here wanted, the writer may be excused for mentioning a circumstance in his own family history. He can trace its course with tolerable clearness for two hundred years, and is pretty well assured that, during the whole of that time, till the generation immediately preceding himself, no representative of the family had more than one son to transmit its name and property. Local antiquaries are familiar with instances of families once numerous in a certain province, but now extinct. The present writer has reason to believe, that his own family existed for more than twice the space of time above mentioned, in one particular place; yet the county in which that place is situated, does not now contain one person of the name.

Were it even admitted that communities are naturally equal in respect of the inclination and power, it still remains to be shown, that these tend to be equally manifested in all social circumstances. The readiness with which the Malthusians have assumed that this is the case, seems to us highly unphilosophical.

In dense communities, where all social circumstances are in the best condition, there are many enjoyments not known in ruder states of society. It may not merely be that these enjoyments compensate for the want of others, but they may absolutely take away or supplant the inclination for those other enjoyments, so as to make the "checks," as far as they are concerned, a mere empty name. Following out this line of argument, supposing it to be sound, we arrive at the conclusion, that, when a country becomes filled up with people, it is also in general attended with circumstances which moderate the tendency to increase, without that being felt as any hardship.

The noted case of Ireland tends to support this hypothesis. Singularly deficient in the compensatory or rather preclusive conditions, this country has long been remarkable for the rapid increase of its population.

The common people, reduced to a degree of poverty which admits of no hope, and exposed to a constant privation of all the ordinary solaces of life, are driven to matrimony as the only comfort in their power, just as others in their condition are driven to the use of intoxicating liquors. The consequences lead to greater poverty, and greater poverty tends to increase the evil; and thus will such a system of things go on until countervailing agencies are brought into operation. Such agencies are now at work in Ireland; wealth and its enjoyments are increasing; and we may therefore hope speedily to see the advance of population in that country less of a wonder than it has been.

Granting the above arguments to be sound, it follows that the stationary condition of the population of old countries is not necessarily to be supposed to be attended with either the hardship of restraint or an extraordinary mortality. If the wealth and ordinary solacements of a people in such circumstances are not in the way of being lessened, they may fairly be presumed to be as well off in all respects as the rapidly increasing multitudes of America.

Where we see the inhabitants of an old country rapidly increasing, we must come to one of two conclusions, either that that country is in a flourishing state, so that there is a kind of bounty put upon children, or that it is in a state of such wretchedness that the intercourse of the sexes is the only attainable enjoyment. With regard to Ireland, we presume there can be no doubt of its liability to pass into the latter category. But the rapid increase of the English people in the last forty years will probably be the subject of a doubt. To determine this question, it might be inquired if the increase of the agricultural products and of the manufacturing industry of the country has been in an equal ratio, and if labouring men, skilled and unskilled, can now obtain for their wages as large a share of the comforts of life as formerly. Notwithstanding popular declamations to the contrary, we suspect this to be the case, and consequently believe the increase of population in England to be, upon the whole, of a healthy description.

POOR-LAWS.

In all stages of society there has existed a class, emphatically termed the *Poor*, composed of persons who, but for the charity of their neighbours, would be nearly or totally destitute, being themselves unable, or all but unable, to supply their own wants. It is easy to see how this has been and must be; for, from accidents in the operation of the natural laws presiding over the birth of individuals, some come into the world without the usual gifts of body and mind required for obtaining a sufficient subsistence; the accidents of life deprive others of the use of their full powers; many reach an infirm old age, without having laid up a store to help them over it; the consequences of vice and error—of all those countless temptations which beset human nature, and from which no one is altogether safe—leave many in a helpless state; finally, in the imperfection of all political institutions, there are circumstances which press severely upon classes and persons, tending to make their own efforts for their subsistence insufficient. The operation of accidents upon one class of parents, and the vices and neglect of others, likewise leave many young and helpless children in a state in which they would be destitute but for the aid of neighbours. All of these causes being inherent in human nature and in society, we may be assured that “the poor we shall have with us always,” however it may be possible, by judicious and humane efforts, to keep their numbers within comparatively moderate bounds.

In an early state of society, the relief of the poor is left to the operation of benevolence amongst individuals; and the destitute are either succoured by those locally near them, or go forth to beg relief in a wider circle. Generally, the efficacy of benevolence for this

end is made the greater, in consequence of the succour of the poor being set forth as a duty in almost all religions. In addition to occasional and particular acts of charity, donations are made and legacies left, for the purpose of affording a more or less regular and systematic relief within certain bounds. As society, however, advances, it is found that the charity of individuals is either an insufficient means of succouring the poor, or is attended with certain inconveniences. The classes of society becoming more detached from each other, cases of destitution make appeal, almost exclusively, to the parties nearest in poverty; while the rich, and the comparatively rich, are saved from all concern in the matter, merely because local and social circumstances spare them a personal connexion with it. A relief by benevolence is found to be oppressive to those who have kind feelings, while the niggardly and ungenerous escape. A dense and highly artificial state of society rendering it impossible to keep watch over particular cases of destitution, the relief afforded is unavoidably partial and unequal—no one knowing the real needs of a petitioner, or how far he is relieved by others; so that a door is opened for the practice of gross imposture, while the more modest poor are probably the least liberally treated. It is also generally found, that this state of society is attended with an increase of the numbers of the poor, rendering individual efforts insufficient, and tending to such disorders, that a public provision becomes necessary as a matter of police. A new principle is then evolved from the natural fact of the existence of a poor class, namely, that the community cannot be safe from imposture, spoliation, the propagation of disease, and other evils, unless it combine to assure itself that no person in the country shall want the necessities of life.

It is then that states begin to make arrangements for the regular relief of the poor; and, generally, these arrangements are of a more or less advanced and efficient nature, in proportion to the advanced social condition of the respective countries. In the most of the Catholic states of Europe, the system adopted consists simply in the ministers of religion taking charge of the voluntary contributions of the people, and administering them to the best of their ability. In Portugal, Sardinia, Venice, France, Belgium, Holland, and some other countries, the same system exists, excepting only that the ministers of religion are superseded in their charge by officers appointed by the state. We need scarcely remark, that the single fact of the funds being voluntary renders it impossible, as to any of these countries, to be certain that the provision for the poor is sufficient in amount. In England, Ireland, Prussia, Bavaria, Wurtemberg, Mecklenberg, Berne, Russia, Denmark, Sweden, and Norway, the principle is recognised that a compulsory provision ought to be made to ensure that all the members of the community shall have the means of subsistence. In England, this has been in operation for nearly three centuries; but, in the most of the other countries enumerated, it is of comparatively recent adoption. In America, all the states of the Union which are of English origin have, from their commencement as colonies, adopted this principle. In Scotland, laws for a compulsory provision have existed nearly as long as in England, but have never been carried out into full operation. In that country, a voluntary system is followed in more than one-half of the parishes, and a compulsory system in the rest, the clergy being, in almost all instances, the administrators; but nowhere is the principle of a legal right in the poor to relief, or, what is identical therewith, of its being the interest of the community that relief be granted, practically recognised.

ARRANGEMENTS FOR THE POOR IN ENGLAND.

Acts respecting the poor in England only made arrangements as to the places in which they should beg, until, in 1536, immediately after the dissolution of the religious houses, by which the poor had previously been in a great measure supported, it was found neces-

sary to make an effort to repress the enormous prevalence of vagrancy, by enacting that head officers in parishes, towns, and counties, should take charge of the impotent poor and collect alms for their support, and at the same time use force to compel able-bodied mendicants to work for their own livelihood. This and subsequent acts of a similar character appear in a great measure to have failed in their object, chiefly perhaps from the severity of the penalties imposed for disobedience. In 1572, we find the first trace of compulsory assessment for the poor—a measure then resorted to, apparently, because all other means of collecting money had proved insufficient.

It was, however, by the famous act 43 Elizabeth, c. 2 (1601), that the basis of the present system of poor-relief in England was laid. The professed objects of this law were, "to set the poor to work, to relieve the lame, impotent, old, and blind, and to put out their children as apprentices." To attain these objects, the inhabitants of every parish in the country were required to raise a fund sufficient to maintain their own poor; and the administration of this fund was placed in the hands of parish overseers, under the control of justices of the peace. The leading merit of this act was, its requiring that the claims of the able-bodied for relief should be subjected to a *test*, to prove that the alleged want was not the result of an indolent disposition: *such persons were to receive relief only on condition that they should work for it*. To make this rule certain of operation, an act passed eight years after (7 Jac. I. c. 4) ordered the building of *houses of correction*, to be provided with cards, mills, and other implements, and where the vagrant able-bodied poor should be set to work. This may be considered as the origin of the workhouse system in England.

It is clear from the statutes of this period, that the chief evil which the legislature found itself called upon to consider and provide for, was the indolent and vagrant disposition of a large section of the people. It was not, as now, that many men occasionally find a difficulty in getting work, but that many were unwilling to work, preferring to wander about the country in idleness. It appears that these vagrants were accustomed to stay only for a short period in one place, and to flit about to wherever they thought they would be best supported; nor can it be doubted that, in lonely places, they would not be backward to use means for terrifying the lieges into contributions for their benefit. That, in such circumstances, these people would want all moral culture, and be a source of danger to the community, is of course evident. It required many years' operation of the law to reduce this evil; but at length, about the end of the seventeenth century, it seems to have been considerably lessened. The same class of persons then began to prefer the benefits to be obtained through the claim which the law gave them upon their native parishes, and the evil of vagrancy was gradually exchanged for one of another but less grievous kind—an inclination to a timid and slothful dependence on the relief to be obtained at one fixed place.

The houses of correction were mainly penal establishments; and it was not till 1723, that workhouses, as now understood, were established. An act passed in that year enabled parishes, either singly or in union, to provide themselves with houses wherein to employ the poor; and enacted that, in case any person refused to be relieved in those houses, he should not be entitled to any other relief. This might be severe upon the real pauper, but it effectually unmasked the voluntary one and the impostor, and proved a protection to parishes against the orders of justices, over-liberal of money not their own. The operation of this law was so favourable to the public, that some began to imagine that paupers might even become profitable; and this was partly the cause of an act (22 Geo. III. c. 83) in 1782, usually called *Gilbert's Act*, which threw upon guardians the duty of finding work for the poor near their own residences, and making up what was required for their subsistence out of the poor-rates. The use of the work-

house as a test of real indigence and inability was thus in a great measure undone, and all its benefits in repressing a pauper population lost. Gilbert's act may be said to have been the foundation of all the evils for which the English poor-laws were latterly so remarkable.

In 1795, the price of wheat, which, at an average of the three preceding years, was 54s., rose to 74s., and the condition of the labouring classes consequently became one of considerable privation and hardship. Instead of temporary measures for getting over a temporary difficulty, one of a permanent nature was adopted. The magistrates of Berkshire in that year issued tables, stating what the wages of a labourer per week ought to be, according to the magnitude of his family and the price of the gallon loaf; directing at the same time the overseers, and others concerned in the management of the poor, to regulate their allowances accordingly. The minimum weekly wages of an unmarried labourer, supposing the gallon loaf to sell at one shilling, were set down at 5s.; when married, and having one child, wages were to be at least 6s.; if he had five children, they were to be at least 12s.; if he had seven children, they were to be 15s. In the event of the price of the gallon loaf rising to 1s. 6d., the wages of an unmarried man were not to be less than 4s. 3d. a-week; while the wages of a married man, with a single child, were not to be less than 8s. 3d.; and those of a married man with seven children, not less than 20s. 3d. These regulations, which remind one of the ignorant legislation of the fourteenth century, were made binding, universal, and permanent, by an act passed in the ensuing year (36 Geo. III. c. 23). It cannot fail to be remarked what a mean opinion of the character of the labouring classes of England must have been entertained amongst the more enlightened men of that day, when it was thus thought necessary to undertake for them some of the simplest duties which they owed to themselves, and to make them every where pensionaries upon the public for a considerable part of their subsistence. As an attempt to secure to a portion of the community the same supply of food in scarce as in plentiful years, and consequently to relieve them from the necessity of those retrenchments by which a deficient supply is distributed over the whole year, and absolute famine averted, the act was further liable to be considered as a gross absurdity. The evils of the regulations themselves were increased by peculiarities in the administration, by which the labouring classes became a means of enabling one class of rate-payers to carry on a constant warfare against the pockets of another. The general evils of the poor-laws were much aggravated by the arrangements with respect to *settlement*; virtually, the labouring classes were *imprisoned* in the parishes of their nativity, or where some subsequent circumstance, as apprenticeship, marriage, and inheritance, had given them a claim. Thus, the population was distributed, not as required by the demand for labour, but as certain accidental circumstances might direct; and, accordingly, there were often hordes of useless labourers at one place, and a great amount of labour without hands to undertake it in another. "Practically, in a pauperised district, where the labourers' wages were composed partly of wages and partly of allowance, the married man had no more free-will as to the parish in which he should reside, the master whom he should serve, or the subsistence which he and his family should receive, than the horse which he drove. In parochial language, he *belonged* to the parish in which he had his legal settlement."*. There can be no doubt that the condition of the working-classes in England, during the prevalence of this system, was a species of slavery. The system lasted with little alteration for nearly forty years; but long before that time, its moral evils, and the enormous increase of expenditure which it demanded, had excited great alarm, and made England, with regard to this par-

* *Edinburgh Review*.

ticular part of its domestic polity, a wonder to neighbouring nations. The sum raised for poor-rates in 1776, while the workhouse system of 1723 was still in operation, was only £1,720,316; in the three years after the passing of Gilbert's Act (1783-4-5) it averaged £2,167,749. But the average of 1801-2-3 was £5,348,205; in 1818, a year of scarcity, it reached the enormous sum of £9,320,440; and even in the fair seasons of 1830, 31, 32, and 33, it was above eight millions. This was an increase far exceeding that of the population, and the more alarming as it took place during a period of progressive national prosperity. Almost every where it pressed very severely upon the property of the country, and in some places had even caused property to be abandoned, the rates exceeding all that could be derived from the land.

The evil being generally felt and acknowledged, a royal commission was issued in 1832 for inquiring into it, in order that parliament might apply a remedy. The following is a condensed summary of the report which this body drew up, after a careful investigation conducted throughout every part of England and Wales:—"That wherever the expenditure had most increased, there, also, the industry of the labourer had proportionally degenerated, because in such places subsistence from the poor-rates was more easily obtained than by labour. That under such influences his prudence and thrift were discarded, because they could, with the utmost success, only secure for him, by present sacrifice of enjoyment, the same future advantages of which the parish held out a prospect without the necessity of any sacrifice save that of independence. That his sobriety and temperance were thus left without encouragement, and, on the other hand, exposed to the temptations of comparative idleness, and the facilities for the indulgence in idleness and intemperance which always accompany the growth of pauperism: his respectability of demeanour was now useless, as respectability of character ceased to be relied on as a means of securing employment, itself no longer an object of desire. That in the same proportion as he became independent of regular industry, did he also become independent or regardless of the comforts of his home, which are indispensable to the labourer after a day of toil, but are rarely sought or valued as a change after a day spent in idleness or dissipation. It was also observed that, as the habit of pauperism increased, the standard of subsistence of the labourers in the district was lowered, the relief never being sufficient of itself to maintain the pauper independent of all work; and yet, by rendering him partially so, constantly tempting him to forego that further portion of comfort which was attainable only on the comparatively hard terms of earning it by the sweat of his brow. The standard of the paupers' subsistence being once lowered, that of the industrious labourers amongst whom they lived, and who occasionally felt the effects of their competition, fell also. Where the system prevailed of allowing relief in aid of wages, there the operation was immediate, as all the labourers were at once pauperised, being equally exposed to the effects of a system which left all industry, beyond a certain point, without its reward, and therefore without a visible object. While these influences were destroying the industry and morality of the able-bodied labourers, the bastardy-law was holding out encouragement to female unchastity, in the way of a money allowance for each bastard, which, by its amount, of itself elevated her condition in proportion to the number of her spurious offspring, rendering a mother of several bastards better off than she would have been as a mother of as many lawful children, and securing her a dower which usually tempted some man to marry her; while the same law, by subjecting the supposed father to punishment, often subjected him, at the woman's discretion, to the alternative of marriage or a jail—the former of which was generally chosen as the least present evil. Under these influences female chastity had, in many districts, so far ceased to be valued as a virtue, that not only the woman herself,

but her parents and her husband, seemed, where the law had had its full effect, to have become indifferent to it.

The evils of the system were not confined to the paupers, but extended to all who had to administer the law. So large a fund as between seven and eight millions, administered without any practical responsibility, naturally tempted the cupidity of the officers through whose hands it passed. The office of overseer was, therefore, generally sought by a class of small farmers and tradesmen, to whom the office must have been most burdensome had it been discharged gratuitously as the law provided. It was found that the overseers were usually appointed, in places where the evil had reached a great height, not from the class of the *substantial householders* of the parish, as the statute of Elizabeth requires, but were usually needy persons, to whom the indirect advantages of the office were important, and who were helped into the office by the efforts of persons similarly interested, either as tradesmen of the parish, or as owners of the dwellings which the paupers inhabited, or in other ways, more as receivers, directly or indirectly, of the rates, than as rate-payers. The spirit of the enactment in the 45 Geo. III. c. 54, § 1, which provides that no contract for the lodging, keeping, or maintaining the poor, or for taking the benefit of their work for their better maintenance, shall be valid, unless the person with whom it is made shall be resident within the parish, was fully carried out in practice in nearly the whole of the 15,000 parishes and places separately maintaining their own poor—every tradesman of the parish, and every employer of labourers, being bribed to maintain whatever system the vestry adopted, by a share in the profitable supply of the parish poor, or by the payment of a part of the wages of his labourers in the shape of relief to them out of the rates. The refractory parishioners were constrained to acquiesce, on pain of losing these and similar advantages, which, being withdrawn or denied, left to them only the obligation of paying those rates. To secure the full operation of this system, the parish was not permitted to deal elsewhere for any commodity with which any parishioner could supply it, and was thus usually confined to the worst market for the goods it purchased, in the same manner as, by the settlement laws, it had been cut off from the supply of other labourers while any belonging to the parish remained unemployed.

The evidence seems also to prove that the functions of the magistracy had almost invariably ceased to be applied to the objects for which they had been created. The magistrates of counties were usually too dispersed, and too little immersed in the actual business of the several parishes, to avail themselves of the advantages which the overseers and the other more immediate administrators of the system derived from it. The magistrates of corporate boroughs, towns, and cities, were, however, in many instances, found to be not less rapacious or ready to apply the administration of the law to their pecuniary profit or direct advantage than the parochial officers. But although the magistracy must generally be acquitted of having sought to derive an immediate pecuniary advantage from the administration of the poor-laws, they were none the less ready to pervert the law to purposes utterly at variance with its original purposes and with the prosperity of the community. Very many of the magistrates, influenced by benevolent intentions, were ready on all occasions to admit the claim of the pauper, and to compel overseers to administer relief when they inclined to refuse it: such magistrates were constantly resorted to by paupers in preference to others who more vigilantly examined the grounds of their claims; and a reputation for being the *poor man's friend* was easily earned by the lavish and immoderate expenditure of the fund of the general rate-payers. This reputation was found to be useful in many ways, and was thus sought for political purposes, or for the attainment of local power, or for the mere gratification of vanity, by many magistrates,

whose sympathy for the pauper would never have been excited if it had been incapable of being gratified at the expense of the rate-payers. When it is considered that the county magistrates lived in the midst of a population of willing paupers, and the means of annoyance which the latter possessed, if they found occasion to use it, against an obnoxious person, is also borne in mind, it is not to be wondered at that the magistracy generally purchased the good-will of their neighbours by sacrificing the interests of the rate-payers, whom they never had personally before them, and who were very inadequately represented by the overseer, whose interests were too frequently found to coincide more with the demand of the pauper and the inclination of the magistrate than with the strict line of his duty.*

In consequence of the report of the commissioners, an act was passed (4 and 5 Will. IV.), usually called the *Poor-Law Amendment Act*, by which these monstrous evils were for the most part extinguished, and a return made to the just principles and practices dictated by the acts of 1601 and 1723. Both parties in the state supported this measure in almost all of its provisions,† and it was only opposed by a few individuals. With regard to the impotent poor, this act rather increased than diminished the liberality of the arrangements, while it made several other considerable improvements. The great class of adult persons who, from old age or infirmity of body, are wholly unable to work, were to remain, as before, entitled to a support by means of out-door allowances. Of destitute children, those unlikely from natural defects to be able to win their own bread, were provided for by out-door relief; those, on the other hand, who were likely to prove useful members of society, were taken in charge and reared in separate establishments, where their education and training for industrious callings were particularly cared for. Judicious provisions were also made for their being ultimately set at work in the world, as apprentices. With regard to illegitimate children, several former provisions of evil tendency were annulled, and it was provided that no regard should be paid to them till they became actually chargeable upon the parish, when relief should be extended through the mother, she being in this respect treated as a widow. Persons unable to support themselves through accident or from sudden and dangerous illness, were to receive temporary relief, and to have all necessary medical attendance. Insane paupers were to be placed in proper asylums at the expense of the public.

The provisions for *able-bodied claimants* formed the most important part of this act, as indeed it was in this department that the abuses of the old system were the most glaring. The main feature of the new arrangements was the erection of workhouses by unions of parishes, where relief should be affixed to able-bodied

claimants, on the condition of their giving their labour in return, and submitting to the rules of the establishment. This was only a revival of the *test* applied by the act of 1723, the object being to check applications for relief from the slothful, and to throw upon the able-bodied in general the duty, which is every where else the lot of free labourers, of finding work for themselves. The new law contemplated that the food and accommodations of the workhouse should be good and sufficient, but yet not quite so good as those which the free labourers of the district could obtain by their own exertions; so that it might, upon the whole, be more agreeable to the able-bodied man to work for himself than become chargeable. At the same time, it being acknowledged that a change from one system to another could not be expected to be suddenly effected, provision was made for enabling the administrators of the law to exercise a humane discretion in applying the new regulations.

Some material changes were made in the machinery for the administration of the poor-laws. The rate-payers elect for each union of parishes a board of guardians, each rate-payer having votes in proportion to his property, and the proceedings of these boards are under the control of a central board, composed of three commissioners appointed by the crown. Under the chief commissioners, there are twelve assistant ones, each of whom inspects a particular district, and reports upon whatever he sees amiss, with a view to its being amended.

Gradually, under the operation of the Poor-Law Amendment Act, the greater part of England has been formed into unions, each under a board of guardians, and each provided with a workhouse. Down to 1841, there were 588 unions formed, including all the parishes excepting about eight hundred, and a population, by the census of 1831, of 12,162,031 persons. In the first year of the new system, the commissioners issued a general order, prohibiting relief in money to the able-bodied in the employment of individuals, thus throwing their entire support upon their masters. In the second year, they began, in a cautious manner, in obedience to the spirit of the act, to put a stop to out-door relief to the able-bodied—meaning labourers who, with their families, are in health, but excepting widows with young children. This order was issued at first to sixty-four unions, and afterwards it was applied to others, until the total number to which it was extended was, in May 1841, 457, comprising a population, according to the census of 1831, of 7,372,021 persons. By these means the expenditure upon the poor was reduced from £7,511,219 in 1834 to £4,044,741 in 1837, or almost to one half. Since 1837, the expenditure has again been on the rise, and in 1840 it was £4,104,686.

The first effects of the step put to the allowance system were most surprising. The so-called surplus population—the hordes of unemployed men who had required to be partially or entirely sustained by the parish funds, who had been condemned to stand in the parish pound for days, and spend half their lives in a kind of idleness in the parish gravel-pits—disappeared as if by magic. It was found that, left free to seek employment where it could be had, and furnished with the usual motives to exert their industry, they all obtained employment. On this subject the earlier reports of the commissioners gave some valuable information, showing how delusive must have been those views which held forth the population as redundant, and as needing artificial support. The whole seemed to become of derangement. Once disengaged from the trammels which confined men to certain spots of ground and put a bounty upon their remaining idle, the people quickly fell once more into natural arrangements, and there was an independent maintenance for all. To quote an able writer on this subject:—"When the bonds which confined them to their parishes were broken, they distributed themselves where their services were most wanted. When they were allowed the free disposal of their services, they endeavoured to make those services valuable.

* McCulloch's Statistical Account of the British Empire, vol. II. pp. 615-16.

† To prove what is here stated, all who know any thing of parties, and their connexions in this country, will be ready to own that no better means could be devised upon than to make such extracts as the following from the two leading Reviews—

The *Edinburgh Review* of March 1834, after remarking that the "intended beneficence of the allowance system, and proved a 'bitter curse' that it robbed the rate-payer to pay farm labour, and enslaved the labourer; adds that 'its abolition is the imperative duty of the legislature. We say abolition, for nothing short of this can be of any material service.'"

The *Quarterly Review* of January 1834, after making an extract from the part of the Commissioners' Report drawn up by Mr. Chubbuck, says, "It is gratifying to us to find the unanimous opinion of the allowance system here inserted upon so strongly. We might have wished this suggestion to have taken precedence of every other, as being by far the most important and most practical of every other. * * * An improvement in the management of workhouses is highly necessary. They should be made places of moral instruction, and should be so conducted as to render them a school for the education of all who are confined to them, and a place of refuge for all who are unable to support themselves within their walls of reform, and should be, as far as possible, and the last resource of these unhappy beings, by their honest exertions, obtain a maintenance elsewhere."

When the application of more efficient labour increased the employer's returns, and at the same time reduction of rates diminished his out-goings, he had a larger fund for the purchase of those services. The redundancy vanished with its causes. The able-bodied pauper is the result of art. He is not the natural offspring of the Saxon race. Unless his pauperism is carefully fostered by those who think it their interest to preserve it, he rapidly reverts to the *normal type*—the independent labourer.*

The union workhouses are in general remarkably well-arranged establishments. The food, both in quality and quantity—the accommodations of all kinds—the moral discipline and order, are in general all that the humane and the enlightened could wish. The arrangements for the education of the young are particularly worthy of commendation. Workhouses are for the most part occupied only by some portion of the aged poor, and by young children. Though held open for the reception of the able-bodied under any exigency to which they may be presumed liable, they are rarely resorted to by such persons, partly because, the labour-market being freed, there is in general no lack of means for an independent subsistence, and partly from the natural dislike to a life of restraint. One regulation of these houses may be supposed to have operated powerfully in keeping idle married men at a distance from them. In most instances, they are not allowed to live in the same part of the house with their wives. Partly this was needful for the sake of order, and to avoid sundry gross evils which flourished under the old system. Partly it is owing to a principle laid down by the commissioners, that a pauper is not entitled to be in this respect on a level with the man who works for himself and his family. The regulation has attracted much censure, and perhaps it would have been better, at least in point of expediency, not to have had it introduced.

The new law was enacted for only five years. It has been oftener than once renewed for a brief period; and there is at this time (Autumn 1841) a general expectation that, before being renewed permanently, it will be considerably altered. Excellent as the measure has been in its main features, and though it has redeemed the English labouring classes from a kind of slavery, it has been the subject of an outcry of the most violent character. This is partly traceable to those who profited by the abuses of the old system, partly to an ignorant sentimentalism, and partly to the arts of politicians. There is too much probability that this outcry will prevail to a considerable extent, and that England is about to see some of the worst abuses of her old poor-laws restored.

ARRANGEMENTS RESPECTING THE POOR IN SCOTLAND.

The poor are provided for in a much more sparing manner in Scotland than in England; and the able-bodied, so far from having even the offer of maintenance in a workhouse, are totally overlooked.

The early acts of the Scottish parliament respecting the poor, contain, like those of the English parliament, only provisions for the repression of begging. At length, in 1579, an act, apparently suggested by one of the English parliament seven years earlier, introduced the principle of a compulsory assessment for the impotent poor, providing at the same time that able-bodied beggars should be punished as vagrants. The administration of this law was committed to justices of peace, which class of functionaries did not then exist, but were contemplated, though no such appointments in reality took place at that period. Acts of 1592 and 1663 ultimately committed the management of the poor, in country parishes, to the heritors (proprietors) jointly with the kirk-sessions—the latter being parochial ecclesiastical courts, composed of the minister and a small body of lay elders—and to the magistrates in royal burghs. From these administrators there is no appeal except to the supreme civil court of the country (Court of Ses-

sion), an arrangement of course equivalent to there being no appeal at all. Three years' residence confer a *settlement*.

In 236 parishes, containing 1,137,646 persons (nearly the half of the population of the country), a legal assessment has been resorted to. In 126 parishes, with a population of 305,654, there is what is called a "voluntary assessment," which may be considered as only a regulated and equitable mode of voluntary contribution. In the remaining 517 parishes, containing a population of 872,626, there is no assessment whatever, and the funds for the poor arise from voluntary contribution, chiefly in the form of offerings at the church doors. The average annual sums collected under this system during the years 1835, 6, and 7, were—by collections at the church doors, £38,300, 10s. 2d.; by other voluntary contributions, £18,976, 10s. 2d.; from sessional fees, &c., £20,604, 12s. 10d.; from assessment, £77,239, 19s. The aggregate is £155,121, 12s. 2d. It is remarkable that the whole sum here described as raised by assessment, being for 236 parishes, including Edinburgh, Glasgow, and all the other considerable towns in Scotland, was just about a seventh more than the sum raised for the poor in one London parish in 1833 (St George's, Hanover Square).* In Scotland, the expenditure for the poor is equal, on the average of the above three years, to 1s. 3½d. a-head on the population; in England, during the same period, the expenditure was equal to 6s. 10½d. a-head on the population.

As might be expected, the provision for individual paupers, is, in Scotland, extremely slender, and almost every where a vast number of claimants are altogether rejected. In the two workhouses of Edinburgh, for example, the average annual expense for each inmate is from £6 to £8. Excepting in these instances, the provision for the poor in Scotland may be said to consist in a small weekly dole of money, considered as a loan or aid, for which the relations of the parties, or the parties themselves, might afterwards be held chargeable, supposing that their circumstances allowed of its being refunded. In the case of persons who, from infirmity, fatuity, or infancy, can do nothing for themselves, and who at the same time have no relations able to aid them, the dole is considered as a full provision for maintenance: from 2s. to 4s. are given in such cases. Where any remains of health and strength exist, the allowance is usually less in proportion, and may be said to range from 6d. to 2s. a-week. It is in these cases considered strictly as an aid, in addition to what the individual can gain by personal exertions. In the unassessed parishes, the average allowance was, a few years ago, £1, 0s. 4½d. per annum. The administrators of the funds (usually the kirk-session) subject every application for relief to a rigid scrutiny, and never continue any relief when they think it ceases to be strictly necessary. Generally, it may be said, the provision is more liberal in towns than in the country, and in the Lowlands than in the Highlands. In the last districts the funds for the poor are extremely small. "There is something," says a late writer, "approaching to the ludicrous in finding the minister of Alesness, in Ross-shire, saying, in his statistical account, that people come to his parish for the benefit of its poor allowance: the fund is £58, 18s. 4d., divided among 110 paupers, the highest annual allowance being £1, and the lowest 6s. If we make allowance for a resident and humane landlord, and take a glance at the provisions in the neighbouring parishes, we shall find, however, that this choice is not made without reason. In the very useful report of the General Assembly in 1839, we find that Dingwall, the immediate neighbouring parish, gives an annual uniform allowance of 5s.; Foderty gives a maximum of 12s. and a minimum of 2s. 6d.; Cairnach a maximum of 12s. and a minimum of 4s.; Eddertoun a maximum of 8s. 6d. and a minimum of 5s. 6d.; Knockbain a maximum of 10s. and a minimum of 5s.; and Kirkmichael a maximum of 10s. and a minimum of 3s. 6d. These

* The sum raised for the poor in that parish in 1833 was £67,336. The new law reduced it in 1835 to £27,391.

are all annual allowances; nay, there is one parish called Crieich, which gravely reports itself as giving its poor a maximum of 3s. a-year, and a minimum of 1s. Intense, indeed, must be the misery that makes human beings barter independence for sums like these. It is only by knowing such facts that an Englishman can comprehend how the 7s. a-month of Edinburgh and Glasgow, given only to those who suffer under permanent bodily disability, should exercise a power of attraction at 200 miles' distance, and stand forth as the crowning and rich reward of a toilsome journey, and three years of patient suffering. And yet, it seems, that it is not alone among those who obtain the wretched pittance of the Highland parishes that we are to look for the misery of the land; we must take into view those who are denied the boon. The report of the Assembly, speaking of the numbers who in the Highlands and Isles are denied a place on the poor's roll, gives the following characteristic illustration:—

‘The parish of Kilmuir, in the Island of Skye (cutting off the district attached to the parliamentary church of Steinscholl), contains a population of 2275; the average amount of funds, distributable among the poor, is about £3 annually, and a distribution is made only once in two years. The last distribution, prior to the date of the return (21st August 1838), took place on the 3d March 1836, when the sum of £6, 3s. 6d. was divided among 68 paupers.’ The minister states, ‘As the amount of church collections has varied little for several years back, it has been found necessary to restrict the number of paupers to about 60 or 70 at each distribution; but, were the funds of greater amount, it would be necessary to admit no fewer than 200 paupers on the roll.’—*Westminster Review*, xxxvi. 394.

The smallness of the provision for the poor in Scotland, is not to be rashly attributed to want of feeling on the part of the nation. There is in Scotland a strong prejudice against all but self-dependent modes of existence. It is a general opinion that all systematic succour held out to the poor, is productive of evil instead of good, even to the poor themselves. This succour is thought to be particularly detrimental, when it is the result of a fixed assessment or rate, for then it is supposed that the poor are led more particularly to depend on the public charity instead of their own exertions or the kindness of relatives. The smallness of the sums given to the helpless, can only be attributed to this general prejudice against pauper relief; for it may be presumed, that, if there were another feeling in the case, the ordinary slender funds would be augmented by a sufficient assessment. What proves very strikingly that opinion, and not want of benevolent feeling, is the main cause of the small provision, is, that the humbler classes in Scotland have, in general, as great a disinclination to ask public charity, as the wealthier classes to give it. They are generally anxious to avoid resorting to the kirk-session as long as possible, and only do so when all other resources fail. This, we say, is generally the case, for of late years there have been strong symptoms of a change of feeling on this subject amongst the Scottish people.

Practically, the Scottish poor are only in part supported by public provision. Every where, private benevolence steps in to give a share of the maintenance required. There is thus a constant contention between two principles; the session being anxious to throw as much of the burden as possible upon private parties, while private parties, on the other hand, only give what the session pertinaciously withholds. There is also a constant contention between one court of relief and another. A penurious parish, striving, as the phrase is, *to keep down the roll* as much as possible, drives off the poor to other places, where, possibly, an assessment allows of a somewhat handsomer provision, and where a new settlement can be acquired in three years. From the Highlands to the Lowlands, from country parishes to towns, there is a constant flowing of paupers, under the attraction of better allowances. There have even been instances of niggardly parishes extending aid for the purpose of

enabling their paupers to acquire a settlement in towns. It has been found that, amongst the dependants of public charity in Edinburgh, only 871 are natives, while 1931 are from other places—234 of them being from the five northern Highland counties, two hundred miles distant. On the Dundee poor's roll, there are 344 natives, and 655 from a distance. On that of Aberdeen the disproportion is still greater, 420 to 1097.

Till a recent period, scanty provisions for the poor, and the repression of pauperism, were subjects of pride in Scotland. In the evidence taken by the English commissioners a few years ago, the practice of this northern kingdom was held up in favourable contrast with the ultra-liberality of the English system. It used to be a boast with a kirk-session, that it had few or no poor, or that they were kept down at little more than nominal allowances; and the opposite case of an assessed parish would be pointed to, as a proof of the fatal nature of such a mode of poor-relief, the parties altogether overlooking the fact, that they themselves, by denying or stinting relief in their own district, were the great causes of the undue burden that befell their neighbours. It was at that time that Dr Chalmers propounded his scheme for an improved management of the poor, the main features of which were, that voluntary contributions at the church-doors should be the sole fund looked to for public relief (a compulsory tax being considered as tending to throw benevolence out of action)—that elders should take all charge of the poor—that they should, in the first place, when a claim was made, endeavour to make the parties help themselves by their labour; if totally unfit for work, then throw the burden upon relatives; if there were none such with any means, then upon neighbours, no matter how poor; and only when all such means failed, was any public relief to be given;—a plan so obviously inequitable, as tending to save the rich at the expense of the poor, that it has never, to our knowledge, met with a single advocate besides its author.

A considerable change in public opinion upon this subject has been wrought by the publication of a pamphlet by Dr Alison of Edinburgh.* The object of this essay is to prove that the system of excessive restriction pursued in Scotland is attended by evils which ought to make it a subject of shame rather than pride to the community. He contends that, in large towns more especially, it is productive of wide scenes of misery, shocking to all benevolent feeling, and positively dangerous in some respects to the rest of the inhabitants. He shows, that in Edinburgh, Glasgow, Dublin, and other large cities, where there is no adequate system of relief for the poor, fever has been of late years prevalent to a degree quite unknown in any English town—a fact which must in the main be ascribed to the wretched condition of great hordes of people gathered in the meaner parts of those cities. Will it be believed that, in two late years, one-sixteenth of the population of Edinburgh, and one-sixth of the population of Glasgow, were affected by dangerous fevers? The average number of cases treated in the hospitals of Glasgow during the last seven years, has been 1842, while in Leeds, where the inhabitants are a little more than a half, the average for the same period has been 274; and in Newcastle and Gateshead, where the inhabitants are about a fourth, only 39; there being in Bath, during the same period, “only a few cases.” It is true, that want of cleanliness, bad ventilation, and so forth, are proximate causes of fever; but Dr Alison contends, and apparently with success, that destitution is the main and primary cause. He also shows that, as fever is more apt to carry off the adult than the young, it burdens the public with immense numbers of orphans, many of them the children of persons who, if spared,

* Observations on the Management of the Poor in Scotland, and of its Effects on the Health of the Great Towns. By William Pulteney Alison, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh. Blackwood and Sons: 1839.

would have kept them above public charity. Thus, so far, the restrictive system seems to spread, instead of limiting, the evil of pauperism. When a fatal epidemic breaks out in one of the towns in question, subscriptions are generally raised by the wealthy classes to succour the suffering poor; and the evil is thereby perhaps alleviated in some, but only in a slight degree. The victims of the pestilence have been prepared for it by years of unrelieved suffering, and that generosity which once might have prevented disease, is now unable to arrest its calamitous progress.

The popular doctrine in Scotland is that advanced by some political economists, that systematic relief for the poor leads to habits of improvidence, and encourages marriages amongst persons unable to support their offspring, thus tending to increase, instead of diminishing, pauperism. Dr Alison, on the contrary, maintains that "poor-laws, such as exist in England, do not interfere with moral restraint, but support and strengthen it; and that moral restraint is nowhere so feeble, and population (in a long-inhabited country) nowhere makes such rapid progress, as where there is no legal provision for the destitute, and where therefore the prospect of destitution is always clear, obvious, and immediate." A pauper population is increased by the continuance of a state of abject poverty and a want of the necessities of life. He says—"Below a certain grade of poverty, the preventive check of moral restraint has no power. Twenty-five years of observation of the habits of the poor have shown me, that there are none among whom population makes so rapid progress as those who see continually around them examples of utter destitution and misery. In such circumstances, men hardly look forward to the future more than animals. It is easy for us to say, that by cutting off from a poor family any prospect of relief, in case of destitution, we can make them careful and prudent. The practical result is widely different. Another alternative is uniformly embraced. *They lower their habits*; and those who have not been accustomed to observe them, are not aware how much reduction of comfort the family of a labouring man, disabled or deprived of employment, may undergo, and not only life be preserved, but the capacity for occasional irregular and precarious employment continue. On the other hand, when men are preserved from this state of hopeless and abject destitution, they all (or with few and trifling exceptions) gradually fall, more or less, under the dominion of *artificial wants*, and form to themselves a *standard of comfort*, from which they will never willingly descend, and to maintain which they will keep themselves under a degree of restraint unknown to those of the poor who are continually struggling to obtain the first necessities of life."

The object of Dr Alison's pamphlet has been opposed by various writers; but the views upon which he proceeds have not been satisfactorily replied to, and they have unquestionably made a considerable impression on the public mind in Scotland. The conviction is spreading that the present system is inequitable with respect to districts, and nowhere so liberal as a true policy, not to speak of humanity, requires.

ARRANGEMENTS RESPECTING THE POOR IN IRELAND.

In Ireland, there was till a recent period no systematic provision for the poor, but the country was by no means destitute of institutions designed for their benefit.

Legislative enactments had progressively, during the last century, established county infirmaries, dispensaries, lunatic asylums, houses of industry, and receptacles for destitute infants and old people; and similar institutions, together with schools, lying-in hospitals, houses of refuge, and mendicity houses, had been set on foot in various places by private benevolence. But, while much was thus done for the alleviation of temporary and casual distress, there was a mass of mendicancy, and an amount of general suffering from occasional famine and consequent epidemics, which made Ireland singular

among the countries of Europe. It was calculated that, out of a population of between seven and eight millions, upwards of two millions were in a state not much short of permanent mendicancy. The great bulk of the people being an agricultural peasantry, living on small patches of land, and depending mainly on the potato crop, a failure of that product was attended with wide-spread misery, invariably followed up by destructive fevers. The epidemic of 1817, which was the effect of the failure of the crop of 1816, affected a million and a half of persons, and carried off 65,000. The people, moreover, having no resource when they lost possession of their little pieces of ground, landlords found that they were rapidly losing all power over their property. Desperation made the tenants cling to their ground with a pertinacity which nothing could overcome. A common danger having united them in one common cause, the forcible extrusion of a tenant was resisted by one and all, or, if effected, it was sure to be savagely avenged. Practically, the tenant was able to remain on the ground as long as he chose, without much regard to the payment of rent, unless his *good-will* was purchased either by the new tenant or by the landlord. The inconveniences experienced in consequence of the bulk of the people being thus always on the verge of destitution, and without any resource when they reached that point, had become, in addition to those of actual mendicancy, so grievous, that a poor-law began to be contemplated as necessary for Ireland; and in 1833 a royal commission was issued for an inquiry into the subject.

In consequence of the report of this body, an act was passed (1 and 2 Victoria, c. 56), for the introduction of a modified poor-law into Ireland. In the principal arrangements, those adopted in England under the Poor-Law Amendment Act were followed; and the general superintendence was confided to the same commissioners. The system is still in its infancy; but it has so far worked well. In March 1841, 127 unions had been formed and declared, and 60 workhouses were in progress, or in operation. It is anticipated that three more unions will be all that are necessary.

GENERAL OBSERVATIONS.

Poor-laws are, after all, only an expedient for meeting an evil partly inherent in human nature, and partly the consequence of its erroneous moral and political condition. Were all born equally sound, and were all so instructed and so placed socially that each man realised a reasonable sum for his labour, and was disposed to make a proper use of his gains, there would be no need for poor-laws. Such conditions not existing, this expedient is unavoidably called into use, and we must not be surprised that, as one designed to meet great evils, its own operation is attended by less ones. By far the worst effect of poor-laws is the moral degradation which they produce in those for whose benefit they are established. The man who has to ask for public relief to his necessities, loses from that moment the self-respect on which much of his virtue depends. A fatal lesson is taught him—that his wants may be supplied without his own exertions—and the motive to an independent and industrious course of life is greatly shaken, perhaps destroyed. This is itself an evil of such serious magnitude, that it forms with many an insuperable objection to all regular provision for paupers. Such may be said to have been, till a recent period, the public feeling of Scotland on this question, and it still is the predominating sentiment of a large portion of society in that country. It is an objection which we, for our own part, would have difficulty in overcoming, if we did not see around us the awful effects which an inadequate provision for the poor works, in the present condition of society. Unquestionably, nothing but a consideration of the horrible inhumanity, and the extreme dangers to the common weal, which are inseparable from the neglect or repulse of pauper claims, could excuse the deterioration which we unavoidably effect in a man's nature, by giving him that for which he has not laboured.

Another great evil of poor-laws is, that they take

away part of the fruits of industry from those who have legitimately acquired them, and bestow them upon the idle. Industry is by this means discouraged, and sloth and improvidence are in a proportionate degree fostered. In England, this had reached to an enormous height, and even now the abstraction of five millions from the gains of the industrious, must operate very seriously in retarding the progress of the country. It is, however, as already said, a tax unavoidable in present circumstances, if we would escape more serious evils.

While a reasonable doubt can scarcely be entertained as to the propriety of both succouring the helpless and offering a modified provision to the able-bodied in a needy state, it must be equally clear that the more that habits of foresight and self-dependence are propagated in the country—the more that all-sustaining moral influences are diffused through it—we may expect to see the less need for poor-laws. Although there are upwards of twenty millions in savings' banks, and benefit societies are widely spread, still the great bulk of the labouring classes of this country live from hand to mouth, without any store whatever on which to fall back in the event of sickness or an occasional lack of employment. This is a preposterous state of things. What is to be expected of a people, the great bulk of whom are contented to live with only a little accident between them and a state of dependence on private or public bounty? Sickness is what all are liable to at all times; failures of employment take place at frequent intervals every where. There surely might be some better provision against such contingencies than a public provision, which makes the recipient a degraded man for ever. Individuals might be induced, by an improvement of the moral agencies of the country, to do much for the securing of their own independence; and the remainder of the required provision might perhaps be obtained by systematic contributions from the labouring classes towards a common fund, from which succour could never be a degradation, seeing that they had themselves created it. Proposals of this kind are apt to strike the mind unfavourably, from their being new; but the position at which this country has arrived is in some degree new, and accordingly calls for measures of a different kind from what we are accustomed to contemplate. Certainly, while only the expedient of poor-laws is adopted, the community can never be inspired, in all its departments, with that manly and independent feeling which is the inseparable associate of all the other virtues, and the great distinction between the freeman and the slave.

LIFE-ASSURANCE.

LIFE-ASSURANCE, in its ordinary character, is a means of securing, by a present payment in full, or of an annual payment, a sum to be realised after the decease of the party.

It is obvious that, to many persons, the having this in their power is of great importance. To none is it so important as to individuals in the middle walks of life, who, for the present, are perhaps able to maintain their families in comfort, but being unable to accumulate a large surplus capital, cannot be sure that, in the event of their death, those dependent on them will not be thrown into poverty. To such persons, life-assurance presents itself as a ready and convenient means of providing for those in whom they are interested.

With a certain annual sum laid aside from a professional income, or from the profits of trade, such a person can make sure that, though death cut him off abruptly, his widow and children will have something to look to, either for an entire maintenance, or to aid in enabling them to gain one for themselves. By the same means, an individual, possessing an entailed estate, can make provision out of its current rents for those younger and female children, who, at his death, would cease to be

benefited by it. An individual, also, incurring a risk in behalf of another, or having a large claim upon him in the form of debt, can insure upon the life of that person such a sum as would be sure to cover all loss, in the event of that person's sudden death. There are many other circumstances in which life-assurance may become highly beneficial; but its chief utility lies in securing a certain sum to helpless persons, in the event of the decease of those on whom they depend.

The principle on which life-assurance mainly rests, is one which it has been reserved for modern times to discover, namely, that, while the duration of the life of a single person is of all things the most uncertain, it is possible to ascertain, with tolerable clearness, how many of a multitude of persons of a particular age will die within next year, how many in the second year, how many in the third, and so on. The medium or average gives what is called the *expectation of life* for each person of the set. A certainty, in short, is attained on this proverbially uncertain subject, when we take a great number of persons, and consider them with regard to the circumstances in which they live. It is found, for instance, that, of 100,000 persons, aged 52, residing in this country, the number who will die before another year has elapsed, will be about 1521, or rather more than one and a half per cent. Supposing that these 100,000 persons were to associate for the purpose of making sure that the widows or other heirs of all those who died within a year should have £1000. It would only be necessary, in that case, for each person to contribute as much to a common fund as would make up £1,521,000, or a thousand times 1521; that is to say, each would have to pay in £15, 4s. 2d. It is clear that those who died, or their heirs, would profit to the extent of £984, 15s. 10d.; but without injury to those who survived, for these also had their chance of gaining, for which it was but fair that they should pay. This would be a simple transaction in life-assurance, and may serve to convey an elementary idea of what life-assurance is, though, in practice, the transactions are usually of a somewhat more complicated kind.

An assurance is rarely transacted for a single year. The object of most is to pay a certain sum each year, as long as they live, in order that a sum may be realised at their death. Assurers are also of various ages; the young have the expectation of longer life than the old. It therefore becomes proper that they should pay less than those more advanced in life. Indeed, there ought to be a payment appropriate to each particular age; and this, accordingly, is the case. Another point calls for particular consideration. The payments being made, not to clear off one year's claims, but to make good a sum many years hence, large funds become accumulated, and upon the improvement of these much depends. If a high rate of interest is obtained, the funds experience a rapid increase, and the less payments are required to effect insurances. If, on the contrary, the interest realised be small, the insurers require to make their original payments so much the higher.

Life-assurance is effected in this country either in offices established by joint-stock companies, who look to making a profit by their business, or by mutually assuring societies. The former are shortly called *proprietary*, and the latter *mutual* offices. Offices of the first kind are usually held by a joint-stock copartnership, with a large subscribed capital; and the chief advantage which they hold forth, is the ample security for all claims presented by the capital, and the respectability of the shareholders. In the case of a mutual office, there is only, it may be said, an association of customers, each of whom is concerned in insuring his neighbour. In this case, however, all surpluses, instead of going into the hands of a trading company, remain the property of the insurers, and are liable to be divided amongst them. For a long time, the business was conducted almost exclusively by companies; but it was at length seen that all desirable security was to be obtained on the association principle; and for some years this system has been advancing much more

rapidly than the other. In various instances, companies have scales of charges allowing of a participation in surpluses; and these are usually called *mixed* proprietary and mutual offices.

The existing British offices are about eighty in number, most of them of recent origin. The oldest is the Amicable, of London, established on the mutual principle in 1706. At the time when it was set up, no calculations as to life existed; and the conductors were accordingly obliged for many years to proceed in a great measure at random, charging the same premiums or annual payments for all ages under forty-five! The other offices, dating from the last century, are the following:—The Sun, 1710, proprietary; the Union, 1714, mixed; the London, 1721, mixed; the Royal Exchange, 1722, proprietary; the Equitable, 1762, mutual; the Westminster, 1792, proprietary; the Pelican, 1797, proprietary; and the Palladium, 1797, mixed. Ten were established during the first ten years of the present century:—The Globe, 1803, proprietary; the Albion, 1805, proprietary; the London Life-Association, 1806, mutual; the Provident, 1806, mixed; the Rock, 1806, mixed; the West of England, 1807, mixed; the Hope, 1807, mixed; the Eagle, 1807, mixed; the Atlas, 1808, mixed; and the Norwich Union, 1808, mutual. The rates charged by these offices are very various, but in all cases they have been found sufficient for the risks. In most instances, the companies divide large profits, while the mutual offices have realised equally large surpluses, which they have divided amongst the insurers, in proportions according to the sum assured and the duration of the insurance, or upon some other principle which may be thought preferable.

Life-assurance grew up in the last and present centuries amidst such an imperfect knowledge of the data on which it depends, that there is little to be wondered at in the great variety of rates charged by the different offices. These data are now much better understood, and it has become possible to arrive at a comparatively close estimate of what charges are really required from an individual, in order to make good a sum at his death for the benefit of his survivors. There might be greater closeness still, if the laws of mortality, now so well ascertained, were alone concerned; but the rate of interest upon money also enters into the calculation, and this, as is well known, is liable to fluctuation. Loose as the matter thus remains in some measure, enough is ascertained to admit of an approximation being made to something like a standard for the conducting of this important branch of business.

The rate of mortality and the rate of interest upon money, are the two principal data on which life-assurance practically depends. We shall first consider

THE RATE OF MORTALITY.

Tables of mortality are founded on the assumption that human life is of a certain average endurance; and by means of them we estimate the number of deaths that may be expected among a given number of individuals, from the proportion that has been observed to occur among another class similarly circumstanced.

The tables of mortality adopted in this country as the basis of calculation for insurance companies, are three in number. That known by the name of the *Northampton table*, is the oldest now in use. It is founded upon observations made by the celebrated Dr Price, of the deaths registered for the population of one of the parishes of the town of Northampton, during the years between 1735 and 1780. This table, it is now acknowledged, shows far too high (or rapid) a rate of mortality, owing partly to no effect having been given to the fluctuations in the population of that parish, from immigration and other such causes, and partly to the great improvement which has taken place in the value of life since the middle of last century, consequent upon the introduction of vaccination and other improvements in medical science, as well as in the habits and modes of living of the people. In 1827, a select committee of

the House of Commons, appointed to investigate this subject, reported—"The evidence appears to your committee to be strong and decisive in favour of the use of tables which give an expectation of life higher than the Northampton. In truth, there is not even a *prima facie* case in their favour."

The *Carlisle table* was formed, not from the register of burials among a floating population, but from observations of the deaths which occurred, at each year of life, among a certain stated number of persons in the town of Carlisle. The observations were conducted by Dr Heysham, and the calculations made, in the most scientific manner, by Mr Joshua Milne, author of a valuable work on annuities.

Finally, the *Government tables* were compiled from observations on the progressive mortality occurring among the government annuitants and other selected classes, distinguishing the sexes. They were prepared, under the directions of government, by Mr Finlaison, actuary to the National Debt; and in 1829 were adopted by parliament as the basis upon which their future calculations should proceed. Mr Finlaison's researches established the fact of the longer duration of female life. He also observed "a very extraordinary prolongation of human life" in the course of the time over which his inquiries extended—so great "that the duration of existence now, as compared with what it was a century ago, is as 4 to 3 in round numbers."

Besides these three, a table was framed by Mr Griffith Davies from the deaths reported from time to time among the members insured in the great Equitable Society of London, from its commencement in 1762 down to 1829, which has since been recalculated and continued down to a later period by Mr Morgan, the actuary to that society. This table is very valuable, as confirming the substantial accuracy of other observations, with which it very nearly corresponds. The relation which these tables bear to each other may be seen at a glance from the following table, showing the *mean expectation of life* at various ages according to each.

At Age.	By Northampton.	By Carlisle.	By Government.			By the experience of the London Equitable.
			Males.	Females.	Mean.	
20	33.43	41.46	33.39	43.99	41.19	41.67
25	30.85	37.86	35.90	40.61	38.36	38.12
30	28.27	34.34	33.17	37.57	35.37	34.33
35	25.68	31.00	30.17	34.31	32.24	30.93
40	23.08	27.61	27.02	31.12	29.07	27.40
45	20.52	24.46	23.75	27.81	25.78	23.87
50	17.99	21.11	20.30	24.35	22.33	20.36
55	15.58	17.58	17.15	20.79	18.97	16.99
60	13.21	14.34	14.39	17.32	15.86	13.91

Independently of the acknowledged deficiency of the data on which the first-mentioned table is founded, the mere fact of its differing so much from any other authentic observation, is of itself conclusive against it; and, by parity of reasoning, the close agreement of the others affords strong presumptive evidence in their favour, and imparts a high degree of certainty to calculations based upon them. The *Carlisle table* occupies a mean place between the male and female observations of government, showing a somewhat shorter duration than the mean of these. It also coincides very nearly with the experience of the *Equitable Society*. Considering that it is thus supported by two other sets of observations, and that the whole three extend over a period during which life was not so good as it has since become, the general opinion in favour of the safety of the *Carlisle tables* for life-assurance may be held as well founded. This opinion receives corroboration from the experience of the *Scottish Widows' Fund*, which extends over the last twenty-five years. In 1834, the auditor of that society reported, as the result of a careful investigation, "that the expected number of deaths by the *Northampton table*, which is the table of the society, is to the actual number during the whole progress of the society, as 100 to

57; and the proportion of the expected number by the Equitable experience is to the actual number as 100 to 87." We have understood that the experience of the Scottish Widows' Fund since 1834 is even more favourable to life. If, then, we were to take the whole twenty-five years' experience of this society as a criterion, we should come to the conclusion that the Equitable experience, the Carlisle tables, and the Government mean, are considerably within the verge of safety, while the Northampton tables are so far from the standard of modern life as to be, particularly with regard to the younger class of lives, quite unfit for use.

We have now to advert to

THE RATE OF INTEREST,

meaning the rate at which the yearly premiums may be expected to be improved.

This subject is one which does not admit of the same certainty as the other, and on which, accordingly, there may be great differences of opinion. In 1829, Mr Finlaison writes—"I take it for granted that it will be considered safe enough to assume that money, in a long course of years, will so accumulate, through all fluctuations, as to equal a constant rate of 4 per cent.; because, in point of fact, money has hitherto accumulated at $4\frac{1}{2}$ per cent., whether we reckon from 1803 or from 1783." Other writers, again, and among them Mr De Morgan, looking chiefly to the high price of the 3 per cents. of late years, say that not more than $3\frac{1}{2}$ per cent. should be counted on. Practically, the investments of assurance offices are made on terms much more favourable. It appears, from the published report of the Edinburgh Life-Assurance Company, dated December 1838, that for the three preceding years (1836, 1837, and 1838, when interest was unusually low), the average rate realised on their funds was £4, 16s. 6d. per cent.—about $1\frac{1}{2}$ per cent. higher than the return from the 3 per cents. during the same time. And this, it is stated, was obtained without any part being laid out in the purchase of reversions—on which, it is known, a much higher rate can be got. The example of this office is quoted merely from the circumstance of their report happening to state the precise return at that period. Other Scottish offices are said to have obtained a higher rate. Most of them state that their funds are invested "about," "at," or "above," 5 per cent. Indeed, it is not conceivable that the offices could make such large returns to proprietors and members, in the shape of dividends and bonuses, if they did not generally improve money at about the rate last mentioned. From all of these circumstances, it does not appear likely that calculations for life-assurance, in which the interest of money is assumed at *four per cent.*, will, while Britain remains in nearly its present condition, prove unsound.

EXAMPLE OF LIFE-ASSURANCE CALCULATION.

According to the Northampton tables, out of every 11,650 persons born alive, there will be 46 living at the age of 90. From these tables being ascertained to be unfavourable to life, this must be understood as not strictly the case, but it may be adopted for the sake of illustration. The same tables make it appear that, of the 46, 12 will die in the course of the first year, 10 during the second, 8 during the third, 7 during the fourth, 5 during the fifth, 3 during the sixth, and the last remaining life will fail in the course of the seventh year. It is a favourite mode of exemplifying life-assurance calculation, to suppose these 46 persons, aged 90, associating for the purpose of assuring £100 to each at death. They are supposed to proceed upon the principle of paying all that is required in one sum at first, thus forming a fund which is to answer all the demands which are to be made upon it. In this calculation the improvement of money has been assumed at 3 per cent. The object is to ascertain what sum, by way of present payment, each is to contribute to the fund, so that it may discharge £1200 the first year, £1000 the second, £800 the third, and so on. In order to discharge

L.	L.	L. s. d.
1200, at the end of the first year, the society must be provided with	1200, discounted at 3 per cent., for one year,	1165 1 0
1000, at the end of 2d year,	1000, ditto, for 2 years,	942 12 0
800, at the end of 3d year,	800, ditto, for 3 years,	732 2 0
700, at the end of 4th year,	700, ditto, for 4 years,	621 18 7
500, at the end of 5th year,	500, ditto, for 5 years,	431 6 0
300, at the end of 6th year,	300, ditto, for 6 years,	261 5 0
And in order to discharge the remaining L.100 at the end of the seventh year, with L.100, discounted at 3 per cent., for seven years,		81 6 2

In all, - - - - - L.4225 10 9

This, divided by 46, gives £91, 17s. 2d. as the sum (technically called *premium*) which each person would need to pay in at the foundation of the society. And this sum of £91, 17s. 2d. is the present value of a *reversion* of £100, at the age of 90, according to the Northampton tables, and taking interest at 3 per cent.

Supposing such a society to be constituted, and £4225, 10s. 9d. to be paid in by the 46 members, we shall see how its business would proceed until, at the close of seven years, death put a period to the account:—

The original contribution of L.4225, 10s. 9d. being put out to interest, at the end of the first year amounts to	L.4352 5 2
From which deduct for the twelve lives which fail in the course of the year,	1200 0 0
Fund remaining at the commencement of the second year,	3152 5 2
Which, bearing one year's interest, will amount to	L.3246 16 8
From which deduct for the ten lives which fail in the course of the year,	1000 0 0
Fund remaining at the commencement of the third year,	2246 16 8
Which, bearing one year's interest, will amount to	L.2314 8 2
From which deduct for claims,	800 0 0
Fund remaining at the commencement of the fourth year,	1514 8 2
Which, bearing one year's interest, will amount to	L.1559 16 8
From which deduct for claims,	700 0 0
Fund remaining at the commencement of the fifth year,	859 16 8
Which, bearing one year's interest, will amount to	L.885 10 5
From which deduct for claims,	500 0 0
Fund remaining at the commencement of the sixth year,	385 10 5
Which, bearing one year's interest, will amount to	L.397 1 8
From which deduct for claims,	300 0 0
Fund remaining at the commencement of the seventh year,	97 1 8
Which, bearing interest, will amount to	L.100 0 0
Which will exactly discharge the last remaining claim,	100 0 0

Practically, life-assurance is not effected upon lives so advanced as ninety years. It is common to confine business to ages under 60; and the great bulk of insurers are between 27 and 40, the time about which men in this country begin to feel the responsibilities of a family. But the calculations followed for the various ages are formed exactly in the above mode. All the persons of a particular age in a life assurance society are considered as a distinct group insuring each other. Of those, for instance, at 30 years of age, it is calculated what proportion will die the first year, what the second, and so on; and from each the society looks for such a contribution, present or prospective, as may make up an aggregate sufficient, with the accumulation from compound interest, to pay the sum assured upon each life in that group. It is quite the same thing to the society, or, we shall say, to the general interest, whether the individual insurers pay the whole required contribution at once, or in a series of annual payments, which, as the plan convenient for most, is that generally adopted.

FORMATION OF RATES.

According to the principles of which we have given a slight outline, offices form scales of rates at which

LIFE-ASSURANCE.

they profess to do business. In these rates a great discrepancy exists, for many continue to calculate mortality according to the Northampton tables, which, as shown, give the decrement of life too high; while others proceed upon those more recently formed, which are certainly much nearer the truth; and some, again, assume interest at only three or three and a half per cent., while others deem four not too high. There is also an allowance for the expenses of business to be added to the naked sums required by a regard to mortality and interest, and here also the minds of parties may differ, some allowing more and some less on this account.

In most cases, the charges for life-assurance are considerably within the verge of safety. Hence companies generally divide good profits, and societies realise large surplusages, which fall to be divided among the insurers, in the form of additions to the sums stated in their policies. The scales of the various offices may be

classed in three grades or sets, of each of which we shall give a few examples, endeavouring, at the same time, to show how each particular grade of charges operates in the realisation of profits and surplusages.

Scales of the first or lowest grade are followed as yet by comparatively few offices; but the number is increasing. We presume that they proceed upon modern tables of mortality, and the expectation of four per cent. at an average, as, with regard to one of the following (the Scottish Provident), we have been informed that it follows the government table of males, and calculates upon money being improvable at the above-mentioned rate, adding from 10 to 15 per cent., according to age, for expenses of management, and as a guarantee against any unfavourable fluctuations of mortality and interest. We here, as elsewhere, limit ourselves to offices of undoubted probity.

	20	25	30	35	40	45	50	55	Total Premi- ums between 20 and 60.
Aberdeen Assurance Company, - - - }	L.1 14 7	L.1 18 1	L.2 2 0	L.2 7 3	L.2 14 5	L.3 4 6	L.3 19 8	L.4 19 0	L.129 7 9
Standard L. Assurance Company, Edin., - }	1 12 10	1 17 6	2 2 11	2 9 1	2 17 2	3 6 5	3 19 8	5 0 0

The high premiums borne by the stocks of the two above companies, form a tolerably fair evidence (notwithstanding their having also higher scales) that business can be profitably transacted at these rates. It may likewise be mentioned, that the Edinburgh Life Assurance Company, which presents a scale nearly the same in aggregate amount as the above (£133, 4s.),

divides 6 per cent. upon its stock, the £10 shares of which stand at £14, 10s. in the market. The Scottish Provident is of five years' standing only; but it has done a large amount of business, and its experience as yet tends to show that the rates are considerably within the verge of safety. The following is a selection of respectable offices in which somewhat higher rates are charged :—

	20	25	30	35	40	45	50	55	Total Premi- ums between 20 and 60.
Economic Company, } London, - - - }	L.1 14 7	L.1 19 0	L.2 4 3	L.2 10 11	L.2 19 9	L.3 11 9	L.4 8 0	L.5 10 3	L.141 12 6
Norwich Union Society, Guardian (mixed), - }	1 19 6	2 3 8	2 8 10	2 14 10	3 2 0	3 11 0	4 6 0	5 5 3	142 10 4
Scot. Widows' Fund; } Scot. Equit. Societies, }	2 1 0	2 5 4	2 10 7	2 17 0	3 5 0	3 14 11	4 8 0	5 4 8	146 3 3
	2 1 6	2 5 10	2 11 1	2 17 6	3 5 6	3 15 6	4 8 4	5 4 2	146 12 5

The Economic is a proprietary office, giving three-fourths of the surplusages or profits to the assured. It was established in 1823. In 1834, a bonus, amounting to 16 per cent. on the premiums paid, was declared; and in 1839 there was a second bonus, amounting to 31 per cent. on the premiums paid during the preceding five years. The Norwich Union, in 1816, gave a bonus of 20 per cent. on the amount of premiums deposited by the members insured previous to June 1815; a second bonus of 24 per cent. in 1823; and a third of 25 per cent. in 1830. The Guardian is a proprietary office, in which a proportion of profits not stated is given to the assured. Established in 1821, its first division of profits was made in 1828, and a second in 1835. At each period, the bonuses averaged rather more than 28 per cent. on the amount of the premiums paid thereon during the preceding seven years. The Scottish Widows' Fund and Scottish Equitable have both declared large surplusages. At the division of the first of these highly prosperous societies, in 1825, the policies opened between 1815

(the commencement of the society) and 1820, were declared entitled to 2 per cent. for each year of their currency. In 1832, the same policies received a further addition of 3½ per cent.; and at the same time those opened between 1820 and that time, were declared entitled to additions amounting to 1½ per cent. per annum. In 1839, a retrospective bonus of 2 per cent. per annum was declared on all policies. The effect of these additions is, that policies for £1000, opened before 1820, at whatever age, will amount in 1845 to £1809, 8s. 7d. In 1841, the Scottish Equitable made its first division of surplusages, amounting to 2 per cent. per annum on all policies of above five years' standing; so that the heirs of a person who insured £500 in 1831 (the first year of the society), would now, in the event of his decease, realise £600, and so on in proportion.

A third class of offices, adopting, like the preceding, the Northampton tables, and generally of old standing, and acting upon old calculations, present higher scales of rates, of which we shall give a few examples :—

	20	25	30	35	40	45	50	55	Total Premi- ums between 20 and 60.
Globe Company, -	L.2 3 7	L.2 8 1	L.2 13 5	L.2 19 10	L.3 7 11	L.3 17 11	L.4 10 8	L.5 6 4	L.151 5 2
Sun Company, - - (mixed), - - - }	1 16 11	2 2 6	2 9 2	2 16 8	3 6 6	3 17 8	4 14 2	5 19 11	154 16 6
Amicable Society } (London), - - - }	2 0 6	2 5 6	2 10 6	2 17 0	3 5 0	3 18 6	4 16 6	5 18 0	135 3 6

There are a few offices which charge still higher rates. The aggregate premiums of the London Assurance and National (mixed offices), are respectively £157, 0s. 8d., and £158, 3s. The London Life (mutual) is the highest, the aggregate of the scale being £171, 18s.

It is clear that, if business can be transacted by a company at a profit, on a scale of rates amounting in the aggregate to £129, 7s. 9d. (as in the case of the Aberdeen Company), the last set of rates ought to give companies very large profits, and societies equally considerable additions to policies. The scale of the Globe is also that of the Rock and Atlas, proprietary offices granting a share of profits to the assured. In the Rock, where three-fourths of the profits are divided, policies opened in 1806 for £1000, at whatever age, are now £2001, 11s. In the Atlas, which has not announced to the public the share of profits extended to the assured, policies for £1000, opened in 1816, ranged in 1837 from £1338 to £1789, according to age.

The high rates are defended on various grounds. A company making high charges, and consequently good profits, may be supposed to have more stability than one making moderate charges; while, of a society pursuing business on the same plan, it may be said that the overplus becomes a kind of bank deposit, to be ultimately realised by the depositor. With regard to companies, the defence may or may not be sound, according as business is managed discreetly or otherwise—and there certainly are offices of that nature, entitled to the most implicit confidence, although they present moderate scales. The defence is of greater force with regard to societies; but even there it is not free from

objections. The high-rate societies, proceeding upon the Northampton tables, commit a constant injustice to young and middle-aged members, in favour of the old. The needless amplitude of their funds tends to occasion a less careful use of them in conducting the concern: there is, for instance, a greater temptation to give large commission to persons, who, as it is said, bring business; a practice in no respect different in morality from that of butchers and grocers who bribe cooks and butlers to favour them with their masters' custom. But the greatest objection to a needlessly high scale, is that it must act as an obstruction to the first step in what is generally one of the most important moral acts of a lifetime—the effecting of a life-assurance. We would here be understood to draw a broad distinction between an unsound low rate and one which is sufficient to satisfy a reasonable anxiety for security. Rates much below the first of the above three scales would be decidedly unsafe, taking all likely contingencies into account. On the other hand, it ought certainly to be possible to transact perfectly safe business upon a medium of that scale. Those who, for further caution, prefer the next scale, must be said to pay highly for it, if they resort to a company which gives no share of profits to the assured: if they become members of a society, large periodic additions to policies will be no more than their due.

In order to convey still more distinct notions respecting rates of life-assurance, we subjoin a scale of those which are required, exclusive of expense for management, upon the Carlisle tables, taking money variously at 4 and $3\frac{1}{2}$ per cent. :—

	25	30	35	40	45	50	55
4 per cent.,	L.1 10 4	L.1 15 1	L.2 0 5	L.2 7 6	L.2 15 6	L.3 7 3	L.4 5 8
$3\frac{1}{2}$ per cent.,	1 12 1	1 16 11	2 2 5	2 9 7	2 17 10	3 9 9	4 8 2

The rates actually charged by the offices which we have cited, may easily be compared with these. It will be found that the additions made for management and the security of the concern, even to the $3\frac{1}{2}$ per cent. rate, are very considerable. The aggregate of the above ages at $3\frac{1}{2}$ per cent., is £18, 16s. 9d.; that of the same ages by the actual rate of the Aberdeen Company, is £21, 4s. 11d., or nearly 123 per cent. higher; that of the same ages by the Scottish Widows' Fund, is £24, 7s. 11d., or 293 per cent. higher; while that of the London Amicable, is £25, 11s., or above 353 per cent. higher.

MORAL DUTY OF LIFE-ASSURANCE.

On this subject we add some remarks from a paper in *Chambers's Edinburgh Journal*, No. 378. They are conveyed in language which is apt to appear unmeasured to one who has not given the subject much consideration—but, we believe, *only to him*.

“Such being the equitable and beneficial principles on which mutual-assurance societies are established, it is clear that they present, to men in the enjoyment of income, but possessing little property, a most suitable and favourable means of providing, in a greater or less measure, for the endeared and helpless relatives who may survive them. That only about 80,000 persons in the United Kingdom should have taken advantage of life-assurance, being but one in sixty-two of the supposed number of heads of families, surely affords a striking view of—shall we call it the improvidence of mankind, or shall we not rather designate it as their culpable selfishness? For what is the predicament of that man who, for the gratification of his affections, surrounds himself with a wife and children, and peaceably lives in the enjoyment of these valued blessings, with the knowledge that, ere three moments at any time shall have passed, the cessation of his existence may throw wife and children together into a state of destitution? When the case is fully reflected upon, it must certainly appear as one of gross selfishness, notwithstanding that the world has not been accustomed to regard it in that light. It is unquestionably the duty of every man to pro-

vide, while he yet lives, for his own: we would say that it is not more his duty to provide for their daily bread during his life, than it is to provide, as far as he can, against their being left penniless in the event of his death. Indeed, between these two duties there is no essential distinction, for life-assurance makes the one as much a matter of current expenditure as the other. One part of his income can be devoted by a head of a family to the necessities of the present; another may be stored up, by means of life-assurance, to provide against the future. And thus he may be said to do the whole of his duty towards his family, instead of, as is generally the case, only doing the half of it.

It may be felt by many, that, admitting this duty in full, income is nevertheless insufficient to enable them to spare even the small sum necessary as an annual premium for life-assurance. The necessities of the present are in their case so great, that they do not see how they can afford it. We believe there can be no obstacle which is apt to appear more real than this, where an income is at all limited; and yet it is easy to show that no obstacle could be more ideal. It will readily be acknowledged by every body who has an income at all, that there must be some who have smaller incomes. Say, for instance, that any man has £400 per annum: he cannot doubt that there are some who have only £350. Now, if these persons live on £350, why may not he do so too, sparing the odd £50 as a deposit for life-assurance? In like manner, he who has £200 may live as men do who have only £175, and devote the remaining £25 to have a sum assured upon his life. And so on: It may require an effort to accomplish this; but is not the object worthy of an effort? And can any man be held as honest, or any way good, who will not make such an effort, rather than be always liable to the risk of leaving in beggary the beings whom he most cherishes on earth, and for whose support he alone is responsible?”

NEW AND IMPROVED SERIES.

PRICE 1½d.

PAGAN AND MAHOMETAN RELIGIONS.

PAGANISM is a disbelief or ignorance of the only true God, the Creator and Preserver of all; and in this debased and unhappy state all mankind appear to have been, until illuminated by the light of revelation and cultivated reason. In the state of mental darkness in which many savage and but partially improved races are found, Paganism may be said to prevail. Of this Paganism, however, there are evidently various degrees—some forms of religious belief ascending much higher than others, from the blinded reverence of *gods* made from blocks and stones, up to the worship of a plurality of creators, preservers, and destroyers.

It is generally allowed that the lowest forms of religious belief are those which prevail among the Negro tribes in the central and western parts of Africa, and which consist in the reverencing and worshipping of objects usually classed under the name of fetiches. The word *fetish* or *fetich*, which is believed to be from the Portuguese language, signifies any object in nature or art to which, by a process of consecration, a supernatural or divine power is supposed to have been communicated, and which is therefore deemed worthy of religious veneration and worship. A fetish is thus a kind of idol, or visible representation of deity, and may be ranked with the household gods and presiding genii of the Egyptians, Greeks, and other nations of antiquity. The rude natives of Africa seem to possess no rule to determine the kind or number of their fetiches; it is a matter of free choice, so that whim and accident, much more than any definite feeling, settle which shall be the revered objects of their hopes and fears. There are national, local, and private fetiches; and besides one which is the tutelary genius of every single individual, the Negroes provide themselves with many others for particular purposes. Like the ancient inhabitants of Ethiopia, Nigritia, and Egypt, they often take along with them upon their journeys a living animal as a fetish, which is preserved with extraordinary care. Inasmuch, also, as the ancient Egyptians and their neighbours went to war on account of injury or insult to their gods—on one occasion there was a furious religious war between the cat and rat worshippers—so vindictive wars and dissensions spring up between Negro tribes, if either maliciously or accidentally kill or injure a fetish of the other.

The Moors of Northern Africa, who, as Mahometans, are opposed to the worship of idols, are attached to fetishism. They honour the fetiches as divine beings of an inferior rank, and carry them about their persons as amulets or charms. In Whiddah, and other parts of Africa, towards the south, a small insect, called the creeping-leaf, is highly honoured; he who gets a sight of one considers it a happy omen, and he who kills one despairs of success; the serpent, also, is worshipped as a fetish in temples by priests set apart for the purpose. In Benin, fetiches are more numerous, and, in part, of an entirely different description. The whole material

universe is believed to be animated and furnished with spiritual powers; water, land, animals, stones, trees, and vegetables of every description, are all full of divine spirits and secret influences. He who makes any eatable article his fetish, touches nothing of that sort whatever, whilst he consumes, without the slightest hesitation, what others consider holy. There is a depth and mystery in this superstition which cannot be very clearly understood. As far as can be reasonably conjectured, this species of fetishism implies a connexion between the visible and invisible, and that every thing may by certain means be made to have a relation to man and his destiny. The quality of the thing arbitrarily set apart and invested with an attribute of divinity, is of no consequence; it may be a piece of bone, rag, egg-shell, or clay, indeed no matter what; there must merely be a belief of a relation subsisting between it and man, which relation often commences only for the first time when the thing is consecrated; in a word, every thing properly consecrated and revered as the residence or tangible investiture of deity, is supposed to have a divine power, which, when evoked, is able to incline the Deity to comply with the wishes of men. Under different names, this superstitious reverence for visible objects has prevailed in all ages and countries. At Cape Coast there is a rock projecting into the sea, invested with the character of a fetish, and worshipped by the priests, who annually offer sacrifices to it, with ridiculous gestures and strange invocations. In the great temple of Mahometanism at Mecca, there is a stone which is the object of unbounded respect and adoration. The Lacedæmonians had a sacred stone, which, at the sound of a trumpet, is said to have raised itself to the surface of the water, from the bottom of the Eurotas. The ancient Germans and Gauls had also their holy rocks, caves, seas, springs, and trees, which afforded miraculous aid, and delivered oracles. In Iceland there was a stone in which a divine spirit was supposed to reside, and was therefore an object of religious worship. The Laplanders had a sacred mountain and a consulting drum. All these superstitions are not a whit more respectable than the belief of the Negroes in fetishism; they are, indeed, almost the same thing.

According to the visionary ideas of some ancient sages, a divinity was supposed to reside in matter, and to be liable to be roused from its latent state into activity, by means of consecration and the performance of solemn mysteries. In some of the islands of the Pacific, if any person wishes to protect his property, such as a house, field, or place of sepulture, from robbery or intrusion, he declares that it is *tabooed*, or placed under the guardianship of his gods; and the belief that such is the case being universal, the property is safe from aggression. Mr Ellis, in his "Missionary Tour through Hawai," mentions some interesting particulars regarding the superstitious delusions of

the natives, which incline us to think that these remotely situated people must have had some early connexion with the ancient natives of Asia and Africa, from whom the Greeks and Romans imported their learning and mythological observances. These Hawaiins, as we are told, previous to their embracing Christianity, believed in a number of ideal gods, who were ministered to by priests, and were propitiated by sacrifices of animals: in making these sacrifices, the diviners observed "the manner in which the victims expired, the appearance of the entrails, and other signs. Sometimes, when the animal was slain, they embowelled it, took out the spleen, and, holding it in their hands, offered their prayers. If they did not receive any answer, war was deferred. They also slept in the temple where the gods were kept, and after the war-god had revealed his will by a vision or dream, or some other supernatural means, they communicated it to the king and warriors, and war was either determined or relinquished accordingly." The images of the gods who constituted the guardians of the tabooed places of sepulture, are described as figures oddly carved in pieces of wood; these were stuck on the fences and trees of the enclosure, and with their horrid aspect and ragged garments, seemed no improper emblems of the system they were designed to support. Adjoining the sacred enclosure, the author was shown a *Pahu Tabu*, or city of refuge, which was open for the reception and security of all classes of delinquents, and resembling in its regulations the sanctuaries of antiquity. These, and some other circumstances mentioned by Mr Ellis, open an interesting field for speculation on the probable connexion of ancient and modern superstitions, or at least on the similarity of the delusions by which the untutored human being has in all ages been affected.

Fetichism has long been practised among the Negroes of the West Indies, under the name of *Obeah* or *Obi*—a term most likely originating in Egypt and the adjacent parts of Africa, where anciently there was a deity of a demoniacal character, with the name Ob, or Oub, and from which Moses commanded the Israelites to abstain from making inquiries. Obi is therefore one of the exploded oracles of the ancient world, which has been carried by captured Negroes to the West Indies, and there set up as an oracle and the patron of incantations, charms, and all other superstitious delusions. The adepts who practise this kind of fetichism are called Obeah-men, or Obeah-women, for both sexes engage in the mysteries of this species of jugglery and imposture. We believe, that since the abolition of slavery in the West Indies, and the spread of education and Christianity, the practice of Obi has gone out of repute and notice.

At one period the religion of the Parsees or Fire-worshippers existed throughout Persia and other parts of Asia, but is now confined chiefly to the deserts of Caramania, towards the Persian Gulf, where it is followed by the Guebres or Giaours (infidels), as they are called by the Mahometans. The great prophet or improver of the Parsee religion was Zoroaster, who flourished about two thousand years ago, and taught the doctrines of there being an eternal spirit of Good or Light (Ormuzd), and an eternal spirit of Evil or Darkness (Ahriman), with a vast number of inferior good and bad genii. In this there was a glimmering of a pure theism; but besides a variety of absurd imaginations respecting the organisation of nature, the belief in one God was obscured by a typical worship of the sun, and of fire, both being supposed emanations, or at least emblems, of the spirit of Good and Light. Fire-worship, as practised by the Persian magi, disappeared before the spread of Christianity and Mahometanism, and, as we have said, exists chiefly among the Guebres, a detached remnant of the old Persian nation.

HIINDOOISM.

Hindooism or Brahminism is the religion professed by a majority of the inhabitants of Hindostan; and while possessing the force of great antiquity, it is supported by a skilful priesthood and the division into castes, ren-

dering it the most ineradicable of any system of false belief and worship which exists.

The Hindoos recognise the existence of a supreme and invisible Ruler of the universe, entitled Brahma, but at the same time believe in the existence of other two deities, one of whom is Vishnu the Preserver, and the other Siva the Destroyer. Previous to the creation, Brahma is said to have reposed in silence and self-absorption—a mode of existence considered by the Hindoos as the most perfect and god-like. Having a desire to draw out of his own divine essence a glorious creation, to supplant the deep primeval gloom, he by a thought created the water, and deposited therein a golden egg, blazing like ten thousand suns, which remained inactive for millions of years, till Brahma, who lay enclosed in this shining receptacle, by the energy of his own thought, split it asunder, and sprang forth the Divine Self-Existing, famed in all worlds as the creator of rational beings and the forefather of all spirits. Brahma is represented as a golden-coloured figure, with four heads and four arms; but although he gives name to the great caste of the Brahmins or priests, no sects derive their appellation from him; he attracts little attention or worship, and he has neither temples erected, nor sacrifices offered to him, nor festivals celebrated in his honour.

Vishnu makes a very conspicuous figure in the sacred annals of India, and the fundamental idea of the Hindoo religion, that of metamorphoses or transformations, is exemplified in the *avatars* or appearances upon earth of this deity. In his character of preserver, or rather deliverer, he has, say the Vedas, interposed whenever any great calamity threatened the world: and thus the great ends of his providence are brought about by the various incarnations of the Hindoo deity. Of these transformations there are ten, and they fill up the Indian *yugs*, which compose a certain series of periods intended to effect a junction with God, and comprising 4,320,000 years. The *yugs* have been considered as an allegorical description of the year, divided by the solstices and equinoxes, and of the precession of the equinoxes. Nine *avatars* have already taken place, and the tenth is yet to come.

It is unnecessary to dwell at any length on the wonderful and ridiculous *avatars* of Vishnu. He first appeared in the character of a fish, for the purpose of recovering the sacred writings given by Brahma, which had been swallowed by a giant (typical of the rebellious human soul), and buried along with himself in the depths of the ocean. He successively appeared as a tortoise, a boar, a man-lion, what is called the Brahmen or lingam dwarf, and so on. The transformations are of the most ridiculous nature; and were we to recite them, they should only excite pity for the ignorance of the wretched believers in such absurdities.

In his subsequent *avatars* under different forms, Vishnu delivered the world from successive monsters and giants which threatened its tranquillity. In the ninth *avatar*, which is supposed to have taken place in the year 1014 before the Christian era, Vishnu assumed the form of Boodh, the author of a rival creed distinct from that of Brahma. It appears pretty evident that Boodhism at one time very extensively prevailed throughout India; and several great dynasties, particularly that of Magadha, were Boodhist. But a war having taken place between the devotees of Brahma and those of Boodh, the latter were worsted, and dispersed throughout the countries to the east and north of Hindostan, and Boodhism is no longer professed in India. The rival systems will be noticed after we have described the other deities, male and female. In the tenth *avatar*, Vishnu will descend to the earth mounted on a white horse, and armed with a scimitar blazing like a comet, to root out evil from the earth, and eternally to punish the wicked. Vishnu is represented of a black or blue colour, with four arms, and a club to exercise chastisement on the wicked. The emblems under which he is represented refer to his vindictive character. He has three eyes, to denote the three great

divisions of time—past, present, and future. A crescent in his forehead refers to the measuring of time by the lunar revolutions, as a serpent denotes it by years; and the necklace of skulls which he wears, the extinction of mankind in successive generations.

The third member of the Hindoo triad is Siva the Destroyer. It may be here remarked, that the distinguishing appellations applied to these deities are not altogether characteristic of their functions—Vishnu the Preserver frequently employing himself in acts of destruction, and Siva on the other hand in acts of beneficence. But much vagueness, inaccuracy, and confusion, prevail throughout the whole of the Hindoo creed; and this no doubt arises from the love of the marvellous and indescribable, by which they are led to grasp at phantoms of thought as undefinable as they are impalpable. Siva, it appears, has had an equal share of personal adventure with Vishnu, although the characters which he assumed were not so various, nor his exploits so important or striking. His female partner is called Doorga, and to her the appellation of destroyer is more applicable than to him. She is the chief amongst the female deities; in short, the most formidable and warlike personage of the Hindoo pantheon. She has rivalled Vishnu in the number of forms which she has assumed, and the conflicts in which she has borne the most conspicuous part; and the giants and others who have fallen victims to the prowess of her arm, occupy a prominent place in the wild records of Hindoo mythology. As an object of adoration, the appearance which she is made to assume shows a remarkable obliquity of moral vision in those who framed at first, and those who worship still, this horrible personage. Under the name of Kalee, she is black, with four arms, wearing two dead bodies as ear-rings, a necklace of skulls, and the hands of several slaughtered giants circling her waist like a zone. Her eyebrows stream with blood; and not content, as the male divinities generally are, with the simple productions of nature, her altars are made to flow with the blood of animal oblations. Old records even give directions how human sacrifices are to be offered to this cruel goddess. India has no deity more popular, not only amongst banditti, who hold her in especial veneration, but with the more reputable classes of the community, who offer lavish gifts on her shrine. The disgrace of her religion consists in the worship of impure imagery, which it is impossible to mention.

It is unnecessary to enumerate even the more important of the minor deities; as for the whole, they are altogether innumerable. Some have taken the trouble to reckon up three hundred and thirty millions of them. There are gods of the elements, of war, of the sun, of the winds, of fire, of water, and so on. Every river, fountain, and stream, is either a deity itself, or has one presiding over it. The worship or deification of the Ganges forms a distinguishing element in the belief of the Hindoos. Into this large river, all who dwell within a certain distance of its banks crowd morning and evening to bathe; and the water of this sacred stream is carried to all parts of India, and is sworn by in courts of justice. At Allahabad, where the streams of the Ganges and Jumna unite, the country for many miles round is considered sacred ground; and so great is the number of pilgrims who resort thither for bathing, that the vazier has received in one year half a lac of rupees for permission to enjoy the benefit of immersion in the sacred flood. Oftentimes may be witnessed children hurrying their parents to the river side, fearful lest they should die before being able to reach its banks. Nothing can be more distressing to the feelings than to behold these poor expiring creatures, some calling upon Rham, some upon one of their false gods, others upon another, with their bodies half in the water and half out, the rising tide soon to overwhelm them. Many are laid where the tide cannot reach them, and their case is more pitiable still. Beneath a burning sun, they are left without

food, and many of them, who would no doubt recover from their diseases if proper attention were paid to them, are literally starved to death, or devoured by jackals at night.

Amongst the degrading doctrines of the Hindoo faith, a veneration for and even a worship of members of the brute creation, is not the least remarkable. The cow, in particular, commands the most exalted reverence; and this venerable quadruped may be seen in cities sauntering up and down in the most public places, perfectly at her ease, and calling forth expressions of profound respect. The monkey likewise ranks amongst the higher grade of animals, and is allowed to roam at large wherever he lists—a chartered thief, now laying the confectioner's sweetmeats under tribute, and anon taxing the fruiterer for a portion of his juicy store. But this superstition reaches its climax in the hospitals which are erected for affording shelter and succour to sick and infirm brutes, including lice, fleas, and other insects. It must be an exceedingly nice investigation for those who preside as medical attendants over such institutions, to determine the state of health of such patients. Other animals besides these are held sacred, but some quadrupeds are treated with great cruelty. The draught horses, in particular, Bishop Heber informs us, are barbarously abused; nor is there much sympathy shown to human beings, who are allowed to perish from disease or hunger under the canopy of heaven, without awakening a sigh in the bosoms of the onlookers. Lepers are regarded as objects of divine wrath, and are treated accordingly, sometimes being burned or buried alive.

The peculiar character of the Hindoo creed is derived from their tenet respecting the transmigration of souls. The spirits of the dead are said to enter a receptacle corresponding to the previous character of the individual. The immortal part of the just and good, however insignificant the person may have been, migrates into a hermit, a Brahmin, a demigod, and so forth, rising in dignity according to the degree of merit. The wicked, on the other hand, not only are degraded as human beings, but are compelled to lodge in the bodies of animals. The Hindoo oracles endeavour to establish a degree of conformity between the punishment awarded and offences committed. The pilferer of grain is metamorphosed into a rat, and he who stole fruits or roots becomes an ape. Others are degraded into worms, insects, and so on. The person thus lowered in the scale of creation, must pass through a long succession of degraded births before he can re-assume the human form. This system of rewards and punishments, although confined to the earth, does not exclude the belief of a heaven and a hell hereafter. The celestial mansions, like those of the Mahometan, are replete with objects of voluptuous enjoyment; but only Brahmins and persons of high attainments or great sanctity are permitted to enter these blissful abodes. Some ardent devotees aspire to a higher destiny, and hope to be absorbed into the essence of the supreme being, where they shall repose for ever on an unruffled sea of bliss. The place of final punishment, in like manner, consists of different compartments, the penalties inflicted in which correspond to the iniquities of those who are doomed to enter their dismal precincts.

The devotion of the Hindoos consists in a system of ceremonious observances, not only troublesome in themselves, but encroaching on the moral duties, nay, the whole business of life. Such a stock of atoning merit is by this means conferred, that the weightier matters of the law seem to be superseded; at all events, this external devotion is not inconsistent with the most scandalous crimes. The observances commence in the morning with ablutions and prayers, the worship of the rising sun, in the inaudible recitation of their holy writings, in meditation, and the like. The five sacraments are then performed, which are, teaching and studying the sacred books, offering cakes and water, an oblation of fire, in giving rice and other food to living creatures, and in receiving guests with honour. The

whole of these ceremonies are necessarily abridged, for the entire day would scarce suffice for their perfect performance. The early Hindoos seem to have borrowed, and to have greatly extended, the typical impurities of the Mosaic law; and the rules on this subject, pointing out the causes of defilement and the modes of purification, are numerous and absurd. The death or birth of a child, touching a dead body, a newborn child, an outcast, and so on, render people unclean; and the modes of purification are either bathing, stroking a cow, looking at the sun, or having the mouth sprinkled with water.

Penance and self-torture are regarded as essential to the attainment of a character for holiness; but in their attempts to suit the amount of penance to the magnitude of the offence, there is almost a total subversion of all moral distinctions. Acts naturally indifferent are classed with heinous immoralities; for instance, eating things forbidden is put on the same footing with killing a friend, and drinking forbidden liquor with killing a Brahmin. A particular class of devotees, called *yogues* or *fakirs*, signalise their piety by enduring the severest tortures with a firmness and perseverance worthy of the holiest cause. These consist in burying themselves in the depths of forests, either in a state of perfect nakedness, or having their bodies coated with ashes and cow-dung; in allowing the nails of their hands and feet to grow till they assume the dimensions and appearance of bird's claws; roasting themselves before huge fires; immuring themselves in the ground, and leaving only a small breathing-hole; going about with small spears or rings pierced through the most tender parts of the body, and hot irons applied to the side; holding their hands above their head till they have lost the power of bringing them down again, and become withered like that of the individual mentioned in the Evangelists; clenching the fists till the nails penetrate the palms; turning their faces to the sun till they cannot regain their natural position, or gazing on his intense blaze till their eyesight is extinguished; lying on iron spikes; tearing the flesh with whips; chaining themselves for life to the foot of a tree; and performing other such-like acts of slow suicide. Some of their attitudes are exceedingly fantastical; for instance, Bishop Heber saw a devotee hopping about on one foot, having made a vow never to put the other to the ground, which was now shrivelled up, contracted, and useless. Begging holds a conspicuous place among the religious duties of the Hindoos. Mr Ward affirms that an eighth part of the inhabitants of Bengal and Bahar subsist in this manner; thus constituting a mendicant population of upwards of two millions. Religious pilgrimages are held in high esteem, and the holy places have generally been established near the sea, the sources and junctions of rivers, the tops of remarkable hills, hot springs, caves, waterfalls, and places of difficult or dangerous access. All the principal roads are crowded with people hastening to these holy places. Some are held in higher veneration than others, and it is no uncommon occurrence, in the crush and tumult of the multitude to reach these Bethsadas, for numbers to be trodden to death under foot, or precipitated into the water and drowned.

The sacred writings of the Hindoos are of two kinds—the Vedas and Shastres. The former may be termed their scriptures, the latter expositions of them. The Vedas are divided into four books, all written in the Sanscrit language. The first book is called *Rig Veda*, which signifies the Science of Divination, concerning which it principally treats. The second is distinguished by the title of *Sheeham*, which signifies Piety or Devotion, and this book treats of religious and moral duties. The third is the *Judga Veda*, which, as the word implies, includes the whole science of religious rites and ceremonies. The fourth is denominated *Obater Bah*, or the knowledge of the Good Being, and accordingly this book comprehends the whole essence of theology and metaphysical philosophy. These various books are acknowledged to be of great antiquity, but abound in

such absurdities as to be of little or no value as historical documents.

The temples for the celebration of Hindoo worship appear to have been in ancient times of the most magnificent description, as is proved by the remains of those of Elephanta and Salsette. The temples of the present day do not exhibit such elaborate grandeur, many containing only one apartment, and few having more than three or four. The crowds which besiege them on solemn occasions celebrate their observances in an open area fronting the gates, so that nothing is required within but accommodation for the images and one or two attendants. The idols are composed of every possible kind of material, from gold down to wood or clay, smeared over with a little red paint. Any figure, either of brute or man, or centaur-like combinations of both, serves for a god, and is revered as such by the ignorant Hindoos, after a Brahmin has consecrated them by a process of solemn buffoonery. When placed in the temple, every image has a daily round of homage performed before it, and is furnished with a regular allowance of food, which, after remaining for a limited time, is served out amongst the attendants. These offerings are profusely lavished on great annual festivals, whilst the multitudes without sing indecent songs, and throw themselves into the most fantastical attitudes and motions. The various articles of maintenance bestowed upon the goddess Kalee, in her temple at Kaleeghata, are considered by Mr Ward as worth L.9000 annually.

There is no doubt that, at no very distant period, the bloody deities of the Hindoos were propitiated with human sacrifices, and, in confirmation of this, some of the rites still remain. Children were sacrificed by being thrown into the River Ganges, until the practice was put a stop to by the British government. Old women are still occasionally burned, in order that their spirits may haunt the spot where they are offered up, and entail a curse upon it. The *suttee*, or custom of a widow burning herself on the funeral pile of her husband, is a well-known rite of the Hindoo religion; and the festival of Juggernaut is celebrated by the sacrifice of numerous victims. This idol-car is a lofty ornamented structure, in which are representations of the god, and of Bala Rama and Soobhadra, said to be his brother and sister. This infernal machine, for it deserves no better name, is dragged along amid shouts of triumph by the infatuated multitude, its path being marked by the bodies of mangled victims, who voluntarily throw themselves before the wheels, and are crushed to death. The most indecent figures are portrayed on the chariots used at the temples. With such an impure religion, it is not a matter of surprise that the state of morals is very low in India.

From time to time during the lapse of ages, various sectaries have arisen amongst the Hindoos, each with peculiar objects of adoration and modes of worship. Brahma, as already observed, is at the head of no sect; and Vishnu and Siva, the two powers next to him, divide in a great measure the worship of Indian devotees. Among forty-three leading denominations, Mr Ward reckons twenty to attach themselves to Vishnu, nine to Siva, four to his wife Doorga, under the name of Saktas, while ten select inferior objects of adoration. The zealous adherents of the rival sects of Vishnu and Siva are avowed enemies, and hold each other up to odium and ridicule. But the most important schism is that between the disciples of Brahma and the adherents of Boohi, to which allusion has already been made. The latter have objects of worship, a creed, ceremonies, and institutions entirely peculiar. Their temples are much more splendid than those of the followers of Brahma, and their priests live in spacious convents. Boohism is no longer professed in India-proper, but there is a sect called the Joinas, very numerous in Western Hindostan. They combine in some measure the practice and doctrine of the two rival systems above named. The Seiks are a sect who have attempted to form an alliance between the Mahometan and Hindoo creed, and with some degree of success.

Decidedly the most vicious part of the Hindoo religion is the division of the people into castes, or distinct classes, for such an arrangement strikes at the very root of social progress, and prevents all rational improvement. The whole Hindoo population is divided into four branches or tribes, denominated Brahmins, Kyetra, Bhysya, and Soodra. The rank, occupation, and duties of these several castes, are fully explained in their Vedas, or holy books. The Brahmins are the priests; they are required to be virtuous, learned, just, peaceable, and self-denying. If these were ever the distinguishing traits of their order, the very reverse are the features of their character now. The Kyetra is the military caste: the Vedas require of them a thirst for glory; to die rather than retreat; generosity and princely conduct to captives. Bhysya form the agricultural part of the community; their duties are briefly defined as cultivators and traffickers. The fourth or Soodra caste, consists of labourers, who are enjoined to serve with patience and fidelity; the former, perhaps, they generally do, but as for the latter, it is only when constrained by fear of punishment or loss of pay. The two middle castes have almost become extinct, or rather amalgamated with the former and latter. Thus, it may almost be said that the whole Hindoo nation is now composed of Brahmins or Soodras, both of which are divided into a great many degrees or sub-castes, so that there are many orders of Brahmins as well as Soodras. Of the latter, the Koit is the highest, and the Hurry the lowest, which caste embraces shoemakers, mat-makers, bird-catchers, tanners, skimmers, snake-catchers, and many others. By this division of caste, no possible means exist for any person to rise in the scale of society; all motives to exertion or mental improvement are cut off; no actions, however noble, no discoveries, however important to society, would ensure honour to a person of low caste; and those of high caste lose no honour or reputation by their ignorance and vice. Whatever be the mental abilities of a Hindoo, if born a Soodra, a Soodra he must remain; if the father be a snake-catcher, all his sons must be snake-catchers too; and the influence of caste follows him through all the ramifications of life. Persons of different castes or occupations cannot eat, drink, or smoke together; neither can they intermarry, nor meddle with each other's employment. If a Hindoo loses caste, which is the case if he breaks through any of the foregoing rules, the most distressing consequences ensue; no one will eat with him, or suffer him to come near his dwelling, or marry his children; his own wife and family disown him; looked upon as an outcast of society, he is deprived of all privileges, or means of comfort as long as he lives; and however respectable he may have been before, the meanest caste consider him a vagabond, and will not associate with him. It is caste that renders so many servants necessary to do the work which one or two might easily accomplish. They are born to one particular department of service, and no other can they perform without losing caste. Thus, the man who fetches water cannot wait at table, nor the man who cooks the dinner serve it up; neither will the person who attends the table sweep the room afterwards—and so on through all the different pursuits of life. A native embracing Christianity loses caste by partaking of the Lord's Supper; it requires, therefore, great fortitude of mind to make a profession of faith in the gospel. There are many who have no caste, having been excommunicated because of some breach of the ceremonial laws of their religion, either by themselves or their forefathers; these are all termed Pariahs, and dare not touch the person, garments, food, utensils, or dwelling of a Hindoo of caste, as contamination follows. The Brahmins are a very lordly domineering race, and exact the most severe homage of the Soodras. They themselves are under great restrictions, as well as the Soodras, particularly in the article of food, being prohibited from eating any thing that has had life, except fish. This probably arises from their belief in the doctrine of transmigration; and as they believe

that although the spirits of their ancestors may have entered the bodies of all beasts, birds, reptiles, and insects, yet they do not enter into another element, so that they may eat fish with impunity. Rice, with spices, milk, and ghee, is their principal diet, although they may partake of the flesh of such animals as are offered in sacrifice to the gods, the laws of the religion permitting this.

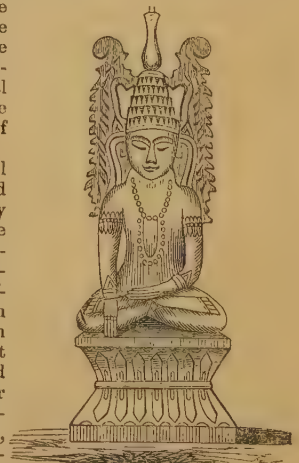

The Brahmins, though all eligible to the priesthood, yet do not all follow it. Some enter the military service of the East India Company, and others become clerks and copyists; but none are permitted to engage in menial employments, and in whatever state they are found, the same honour is paid by their associates, though perhaps not to that degree as if in priestly office. So great is the pride of the Brahmins, that they claim precedence of kings, and the noblest rajah will partake of food cooked or presented by a Brahmin, whilst the meanest Brahmin will not taste that which has been prepared by a Soodra, although that Soodra should occupy a much higher station, civilly, than himself. The religion which inculcates these arrangements, is found to be almost unconquerable by Christian missionaries, for the adoption of Christianity involves a total change of opinion on the constitution of society; and it is a melancholy fact that few except the worst of the Hindoo populace will become proselytes. It is now generally acknowledged, that in order to make any impression on the religion of the Hindoos, it will be absolutely necessary to commence with the instruction of the young in various branches of useful knowledge, to which happily the Brahmins offer no objection, while such instruction is universally desired by the people.

BOODHISM.

Boodhism, or the religion of Boodh or Bhud, is considerably elevated above either pure paganism or Hindooism, and is deeply interesting from being the most prevalent form of religion upon earth. The number of the whole human race being estimated at 965,000,000, nearly the one half, or 400,000,000, are Boodhists. According to the account of Mr Howard Malcom, in his "Travels in the Burman Empire," to whom we are indebted for the following particulars, Boodhism is professed by half of the population of China, Lao, Cochin-China, and Ceylon; all of Camboja, Siam, Burmah, Thibet, Tartary, and Loo-Choo; and a great part of Japan, and most of the other islands of the southern seas, are of this faith. In some parts of India it is the great rival of Hindooism; but its principal stronghold is in the adjoining empire of Burmah.

"Boodh is a general term for divinity, and not the name of any particular god. There have been innumerable Boodhs, in different ages, among different worlds, but in no world more than five, and in some not any. In this world there have been four Boodhs, namely, Kan-ka-than, Gau-na-gong, Ka-tha-pa, and Gaudama. One is yet to come, namely, Aree-ma-day-eh.

It has often been supposed that Boodhism resembles Brahminism or Hindooism, which is a great mistake. No two systems can be more opposite or bear less evidence of being derived from each other. Brahminism has incarnations, but Boodhism admits of none, for it

Gaudama.

has no permanent god. That has a host of idols; this only one. That enjoins bloody sacrifices; this forbids all killing. That requires atrocious self-tortures; this inculcates fewer austerities than Catholicism. That makes lying, theft, and other vices, sometimes commendable, and describes the gods as excelling in these enormities; this never confounds right and wrong, and never excuses any sin. That makes absorption into deity the supreme good; this annihilation. In fine, I know of no important resemblance.

Boodhism inculcates no principle of caste, which is a striking difference from what prevails among the Hindoos; and from this and other causes it is believed to be much more ancient as a religion than Brahminism. The probability seems to be, that Brahminism grew out of Boodhism, and gained power and numbers in Hindostan till the close of the first century of the Christian era, when the Brahmins were able to commence that persecution of which their own records speak, and which drove out the teachers of Boodhism into Farther India, whence it extended into China.

The most extraordinary peculiarity of Boodhism is the want of any existing God. Adoration or respect is merely paid to the image of Gaudama, who was a god at a former period, but is now annihilated, or entered into annihilation. Gaudama was the son of a king, and born about 626 years before the commencement of our era. He had previously lived in four hundred millions of worlds, and passed through innumerable conditions in each. In *this* world he had been almost every sort of worm, fly, fowl, fish, or animal, and in almost every grade and condition of human life. Having in the course of these transitions attained immense merit, he at length was born son of the above-named king. The moment he was born, he jumped upon his feet, and, spreading out his arms exclaimed, 'Now am I the noblest of men! This is the last time I shall ever be born!' His height, when grown up, was nine cubits. His ears were so beautifully long, as to hang upon his shoulders; his hands reached to his knees; his fingers were of equal length; and with his tongue he could touch the end of his nose! All which are considered irrefragable proofs of his divinity.

When in this state his mind was enlarged, so that he remembered his former conditions and existences. Of these he rehearsed many to his followers. Five hundred and fifty of these narratives have been preserved—one relating his life and adventures as a deer, another as a monkey, elephant, fowl, &c. &c. The collection is called *Dzai*, and forms a very considerable part of the sacred books. These legends are a fruitful source of designs for Burman paintings. Of these I purchased several, which do but bring out into visible absurdity the system they would illustrate.

He became Boodh in the thirty-fifth year of his age, and remained so forty-five years, at the end of which time, having performed all sorts of meritorious deeds, and promulgated excellent laws, far and wide, he obtained 'nie-ban,' that is, entered into annihilation, together with five hundred priests, by whom he had been long attended. This occurred in Hindostan, about 2380 years ago, or B.C. 546. At his death he advised that, besides obeying his laws, his relics and image should be worshipped, and pagodas built to his memory, till the development of the next Boodh. He is invariably represented in the same manner, except that sometimes he is made to wear a crown, necklace, ornaments on his arms, &c. I have seen them of all sizes, from half an inch long to seventy-five feet—of wood, stone, brass, brick, clay, and ivory.

The next Boodh is to appear in about seven or eight thousand years from the present time. His height will be eighty cubits; his mouth will be five cubits wide, and the length of the hairs of his eyebrows five cubits. The precise time of his arrival is not predicted. No laws or sayings of the first three Boodhs are extant. Those of Gaudama were transmitted by tradition, till four hundred and fifty years after his decease, when they were reduced to writing in Ceylon, that is, A. D. 94.

These are the only sacred books of the Burmans, and are all in the Pali language. They are comprised in three divisions, each of which is divided into distinct books, or sections. The whole is called the *Bedagat*.

According to the *Bedagat*, the universe consists of an infinite number of systems: each system consists of a great central mountain surrounded by seas, and four great islands, each surrounded by five hundred smaller ones. This earth is in the southern cluster of islands, and we are living on the larger one. It is a convex plane, not a sphere; and is divided by mountains and navigable seas. Below its upper crust, on which we live, is water twice as deep as the earth is thick. The whole is supported on a stratum of air twice as deep as the water. Beneath is a vacuum. The celestial regions consist of twenty-six principal heavens, one above another; and the infernal regions of eight principal places of punishment, each surrounded by sixteen smaller ones. In one of the heavens, there are pleasant habitations for mortals after death; and at the king's principal residence, there is an elephant of stupendous size. This animal is of immense height, and has seven heads; each head has seven tusks, and each tusk seven tanks. In each of these tanks grow seven lilies; each lily has seven blossoms; each blossom has seven petals; each petal bears up seven palaces, and in each palace are seven nymphs, or wives of the king, each surrounded by 500 attendants. Another elephant has one great head, thirty uzenas long, on which the king occasionally rides; and thirty-two smaller heads, for the thirty-two royal princes. Of the principal hells, four inflict punishment by heat, and the other four by cold.

Not only has the universe and all its systems existed from eternity, but also the souls of all the inhabitants, whether animals, men, or celestials. These souls have from eternity been transmigrating from one body to another, rising or falling in the scale of existence and enjoyment, according to the degree of merit, at each birth. This rise or fall is not ordered by any intelligent judge, but is decided by immutable fate. In passing through these various forms of existence, the amount of sorrow endured by each soul is incalculable. The *Bedagat* declares that the tears shed by any one soul, in its various changes from eternity, are so numerous, that the ocean is but a drop in comparison! Existence and sorrow are declared to be necessary concomitants; and therefore 'the chief end of man' is to finish this eternal round of changes, and be annihilated.

The great doctrines of this faith are five—namely, 1. The eternal existence of the universe, and all beings. 2. Metempsychosis. 3. Nie-ban, or annihilation. 4. The appearance, at distant periods, of beings who obtain deification and subsequent annihilation. 5. The obtaining of merit. Of the first four of these enough has been already said. The last is more deserving of notice, embracing as it does the whole system of morals.

Merit consists in avoiding sins and performing virtues, and the degree of it is the sole hope of the Boodhist. The sins which are to be avoided are described in a moral code, consisting of five principal and positive laws:—1. Thou shalt not kill. 2. Thou shalt not steal. 3. Thou shalt not commit adultery. 4. Thou shalt not lie. 5. Thou shalt not drink any intoxicating liquor. These are explained and branched out, so as to include all sins of the same kind, under each head. The first of these laws is extended to all killing, even that of animals for food. The very religious will not kill vermin. War and capital punishments are considered forbidden by the first law.

Sins are divided into three classes:—1. Those of the body—such as killing, theft, &c. 2. Those of the tongue—as falsehood, discord, harsh language, idle talk, &c. 3. Those of the mind—as pride, covetousness, envy, heretical thoughts, adoring false gods, &c. The sacred books pourtray strongly the evils of pride, anger, covetousness, and inordinate appetites. Men are urged to avoid excessive perfumes, ornaments, laughter, vain joy, strong drink, smoking opium, wandering about the streets in the night, excessive fondness for amusements,

frequenting bad company, and idleness. Those who aspire to nic-ban are cautioned to abhor sorcery, not to credit dreams, nor be angry when abused nor elated when approved, not to flatter benefactors, nor to indulge in scorn or biting jests, and most carefully to avoid enkindling strife.

The states of the mind are resolved into three classes:—1. When we are pleased in the possession of agreeable things. 2. When we are grieved and distressed by evil things. 3. When neither do good things gratify us, nor evil things distress. The last is the best state, and in it a man is rapidly preparing for nic-ban. In this there is no small resemblance to the doctrine of the Stoics, and some approach to the Christian doctrine of weanedness from the world. Some of their books abound in good comparisons, such as, that he who runs into sinful enjoyments is like a butterfly who flutters round a candle till it falls in; or one who, by licking honey from a knife, cuts his tongue with the edge. There is scarcely a prohibition of the Bedagat which is not sanctioned by our Holy Scriptures, and the arguments appended to them are often just and forcible.

Merit is of three kinds:—1. *Theela*, or the observance of all the prohibitions and precepts, and all duties fairly deducible from them; such as beneficence, gentleness, integrity, lenity, forbearance, condescension, veneration for parents, love to mankind, &c. &c. 2. *Dana*, or giving alms and offerings. This includes feeding priests; building kyongs, pagodas, and zayats; placing bells at pagodas; making public roads, tanks, and wells; planting trees for shade or fruit; keeping pots of cool water by the way-side for the use of travellers; feeding criminals, birds, animals, &c. 3. *Bawana*, or repeating prayers, and reading religious books.

Alms-deeds are meritorious according to the objects on which they are bestowed, and proportioned to the following scale:—1. Animals. 2. Common labourers, fishermen, &c. 3. Merchants and the upper classes, when in necessity. 4. Priests. For alms of the first class, the rewards are long life, beauty, strength, knowledge, and prosperity, during a hundred transmigrations; for those of the second class, the same during a thousand transmigrations; for the third, the same during ten thousand; for the fourth, a vastly greater number, but indefinite, being graduated according to the degree of sanctity the particular priests may possess.

Many discourses said to have been delivered by Gaudama are given in the Bedagat. In these, the duties of parents, children, husbands, wives, teachers, scholars, masters, slaves, &c., are drawn out and urged in a manner which would do honour to any casuist.

The following is part of one of these, addressed to a distinguished personage, who sought his instruction how to avoid evil:—

‘Know thou, that to keep from the company of the ignorant, and choose that of learned men; to give honour to whom it is due; to choose a residence proper to our station, and adapted for procuring the common wants of life; and to maintain a prudent carriage, are means to preserve a man from evil doings. The comprehension of all things that are not evil, the exact knowledge of the duties of our station, and the observance of modesty and piety in our speech, are four excellent modes of renouncing wickedness.

By ministering a proper support to parents, wife, and family, by purity and honesty in every action, by alms-deeds, by observing the divine precepts, and by succouring relations, we may be preserved from evil. By such a freedom from faults, that not even the inferior part of our nature manifests any affection for them, by abstinence from all intoxicating drink, by the continual practice of works of piety, by showing respectfulness, humility, and sobriety before all, and gratitude to our benefactors; and, finally, by listening often to the preaching of the word of God, we overcome evil inclinations, and keep ourselves far from sin. Docility in receiving the admonitions of good men, frequent visits to priests, spiritual conferences on the divine laws,

patience, frugality, modesty, the literal observance of the law, keeping before our eyes the four states into which living creatures pass after death, and meditation on the happy repose of nic-ban—these are distinguished rules for preserving man from wickedness.’

Pagodas are innumerable. In the inhabited parts there is scarcely a mountain peak, bluff bank, or swelling hill, without one of these structures upon it. Those of Pegu and Siam are all formed upon one model, though the cornices and decorations are according to the builder's taste. In general they are entirely solid, having neither door nor window, and contain a deposit of money, or some supposed relic of Gaudama. From the base they narrow rapidly to about mid-way, and then rise with a long spire surmounted with the sacred tee. Some of those around Ava, and especially those at Pagan, are less tapering, and more resembling temples.

Zayats are not exclusively religious buildings. Some are intended to contain idols, and some are for the accommodation of worshippers and travellers, and for town-halls. The majority contain no idols, and are intended only to afford shelter for worshippers and travellers. Some of these are mere sheds, open on all sides; but in almost all cases they are built in a far more durable and costly manner than dwelling-houses.

Every village has a zayat, where the stranger may repose or stay for many days, if he please; and many a time I found them a comfortable lodging-place. Like the chultries of Hindostan, they are of unspeakable utility in a country destitute of inns, and where every house has its full complement of inmates. Many zayats, especially near great cities, are truly beautiful, and very costly. The ceilings and pillars are not only elaborately carved, but completely gilded, and the stucco floors rival marble in hardness and polish.

Worship is not performed collectively, though crowds assemble at the same time on set days. Each one makes his offerings and recites his prayers alone. No priests officiate; no union of voice is attempted. On arriving at the pagoda, or image, the worshipper walks reverently to within a convenient distance, and laying his offering on the ground, sits down behind it, on his knees and heels, and placing the palms of his hands together, raises them to his forehead, and perhaps leans forward till his head touches the ground. This is called the *sheeko*. He then utters his prayers in a low tone, occasionally bowing as before; and having finished, rises and carries forward his gift, laying it somewhere near the idol or pagoda. Some proceed first to one of the great bells which hang near, and strike several times with one of the deer's horns which always lie beneath. When one goes alone, this is seldom omitted. There are four set days in every lunar month on which the people assemble in greater numbers at the pagodas to offer their individual prayers. These days are at the new and full moon, and seven days after each; so that sometimes their Sabbath occurs after seven days, and sometimes after eight.

Boodhist priests are not a caste or hereditary race. Any one may become a priest, and any priest may return to a secular life at pleasure. Thousands, in fact, return every year, without the least reproach. On becoming a priest, a yellow robe is assumed, and celibacy, with numerous mortifications, is enjoined. Their office may be called a sinecure, as they seldom preach or perform any service, except teaching and giving special religious advice. They are of different degrees of rank, and subsist entirely on the contributions of the people.

Their number is very great. Ava, with a population of 200,000, has 20,000 priests.

In point of moral obligation, and the inculcation of purity of life, Boodhism is infinitely superior to Hin-

Boodhist priest.

doism. It has no mythology of obscene and ferocious deities, no sanguinary or impure observances, no self-inflicted tortures, no tyrannising priesthood, no confounding of right and wrong, by making certain iniquities laudable in worship. In its moral code, its descriptions of the purity and peace of the first ages, of the shortening of man's life because of his sins, &c., it seems to have followed genuine traditions.

At the same time, we must regard Boodhism with unmeasured reprobation, if we compare it, not with other false religions, but with truth. Its entire base is false. It is built, not on love to God, nor even love to man, but on personal merit. It allows evil to be balanced with good, by a scale which reduces sin to the shadow of a trifle. To sheeko to a pagoda, or offer a flower to the idol, or feed the priests, or set a pot of cool water by the wayside, is supposed to cancel a multitude of sins. The building of a kyoung or pagoda will outweigh enormous crimes, and secure prosperity for ages to come. Vice is thus robbed of its terrors, for it can be overbalanced by easy virtues."

LAMAISM.

In Thibet, Tartary, and other parts of central Asia, inhabited by the Mongolian race, Boodhism assumes a different form and name, being more a religion of pure priestcraft and external observance, and including a belief in the continual personal presence of a supreme God. This branch of Boodhism, as it is believed to be, is usually called Lamaism, the word *Lama* literally signifying priest. Like Boodhism, this religion acknowledges no eternal, self-existent being. The idols, to the number of a hundred and eight, are representatives of created beings, who ascended into the rank of gods before the present world was created, on account of their holiness. The chief god is Shigemooi, who appeared in the world for the last time a thousand years before the Christian era, and then instituted Lamaism, with a visible living representative or appearance of himself, called Dalai-Lama, or the Great Lama. The worship of this Grand Lama, therefore, is a principal feature in the system of belief.

It is understood and inculcated, that when the Grand Lama expires in the course of nature, his spirit immediately takes possession of some other body in a supernatural manner, which it is impious to inquire into, and is only comprehended by the attendant priests. In point of fact, the religion which inculcates this absurdity is idol worship under a different name, the idol being a living creature instead of an inanimate object, as in ordinary paganism; and the whole system seems to have been devised in order to support a numerous host of priests and religious establishments.

Dalai-Lama, or the Grand Lama, is at the head of both ecclesiastical and secular affairs in Thibet, which may be considered a theocratical state. The usual residence of the Dalai-Lama is in two monasteries situated in the vicinity of the capital, Lassa, in each of which he dwells alternately. He is surrounded in every direction by a vast number of priests; but no woman is permitted to pass the night in the building where he lodges. This arises, undoubtedly, from the purity which is attributed to him, for he is called the *immaculate*. The natives, as well as a great crowd of foreigners (for all the Mongol tribes in Russia acknowledge him), undertake fatiguing pilgrimages in order to pay their homage to him, and obtain his blessing. He receives them sitting upon a kind of altar, upon a large and splendid seat, with his legs crossed. The Tartars, next to the inhabitants of Thibet, pay him the greatest reverence. They come to him from the most distant regions, and the princes, to whom he shows no more respect than to others, submit to the same ceremonies as their people. He salutes no one, never uncovers his head, rises up before no one, and is satisfied with laying his hand upon the head of his worshipper, who believes that he has thereby obtained the pardon of his sins. His worshippers believe that the supreme divinity lives in him, that he knows and sees every thing in the deepest re-

cesses of the heart, and never needs to make inquiry in regard to any thing. If he does this, it is only that unbelievers and the evil-minded may not have cause for complaint. He sometimes distributes, it is said, little balls of consecrated dough, which the Tartars use in many superstitious practices; but it is not true that balls made from his excrement are distributed, preserved in golden boxes, and even mixed with articles of food. His power was once greater than it is now, and he appointed and deposed the khans; but at present he is dependent on the Emperor of China, although the latter, in a religious respect, is subjected to him. Two Chinese mandarins, with a garrison of 1000 Chinese, are maintained in his capital, and, in the palace at Peking, the Chinese Emperor supports a subordinate Lama, who is sent as a nuncio from Thibet.

When the Dalai-Lama dies, it is then necessary to discover where his spirit has chosen to be born anew. In this case all must submit to the opinion of some of the Lamas, who alone are acquainted with the signs by which he may be known, or, rather, who know what child the deceased has appointed for his successor. The worshippers of the Lama are divided, in general, into two sects, known by the titles of the *yellow* and *red caps*. Each sect is under three Lamas; the former is under the Dalai, Teeshoo or Bogao, and Taranaut Lamas; the latter, under the three shammas. The Dalai-Lama is the most distinguished of all, and next to him is the Teeshoo-Lama, who dwells at Teeshoo-Loomboo, ten days' journey from Lassa. The three shammas dwell in separate monasteries, the most distinguished of which is at Tassasudon, the capital of Bootan. Subordinate to them are numerous priests of different ranks, who are held in great respect, who superintend instruction, and some of whom live in a state of celibacy, according to certain rules, similar to those of the Christian monks. At Lassa alone there are 3000 monasteries.

MAHOMETANISM.

The religion of Mahomet, or Mahomed, and called Mahometanism, partakes of a much more exalted character than any of the mythological superstitions already adverted to, inasmuch as it approaches a pure theism, or a belief in the one true God. This famed religion, which now prevails in Arabia, Egypt, the Moorish states, Turkey, Persia, and is extended in a scattered manner over south-eastern Asia, and numbers 100,000,000 of followers, originated in Arabia at the beginning of the seventh century of the Christian era.

At this period, eastern countries were in a condition to receive a new and vigorously conducted form of religious belief. The scattered branches of the Christian church in Asia and Africa were at variance with each other, and had adopted the wildest heresies and superstitions. They were engaged in perpetual controversies, and torn to pieces by the disputes of the Arians, Sabellians, Nestorians, and Eutychians; whilst the simony, the incontinence, and general barbarism and ignorance which were to be found amongst the clergy, caused great scandal to the Christian religion, and introduced universal profligacy of manners amongst the people. While Christianity, in the manner it was abused by unenlightened followers, was of little avail in civilising the Asiatics, while the religion of the Jews was sunk into comparative insignificance, and while paganism still flourished in the east, Mahometanism was introduced upon the scene, and in a wonderfully short period of time, gave an entirely new cast to manners and form of belief. Arabia being the country in which this new religion was first promulgated, it is considered desirable to mention the nature of the religion which the people previously professed and now abandoned.

"The ancient Arabs are supposed to have been what are termed pure theists; that is, they are supposed to have believed in and worshipped one sole, omnipotent, and everlasting God. Historians, however, have seldom correctly appreciated the meaning of these magnificent expressions in the mouth of a savage. In his

mind such language is connected with ideas and feelings far other than those which a civilised man would express by it. These splendid epithets are the mere expressions of flattery and fear. The Deity, now addressed, and whose favour is the object of present desire, is for the time the sole object of adoration. The very same savage, who believes in a host of gods, will address each of them by the term of THE ONE. If among many deities one is thought more powerful than the rest, he will be the oftenest addressed, the oftenest soothed by flattery. No epithet is so flattering as that which asserts his single existence. It exalts him above all beings, and leaves him without a rival. No epithet, therefore, will be so frequently employed. Being the most constantly adored, this more powerful divinity will have this epithet expressive of his sole existence so frequently connected with his name, that it will at length be regularly attached to, and form part of, that name. This was precisely the case with the Arabian objects of worship. It is strange that, when complete evidence of this fact exists, really intelligent and circumpect historians should have believed in the pure theism of the Arabians. Sale, like many others, was deceived by pompous expressions:—"That they acknowledge one supreme God, appears (to omit other proof) from their usual form of addressing themselves to him, which was this:—"I dedicate myself to thy service, O God!—I dedicate myself to thy service, O God! Thou hast no companion, except thy companion of whom thou art absolute master, and of whatever is his." In the very next passage, however, Sale adds, 'They offered sacrifices and other offerings to idols, as well as to God, who was also often put off with the least portion, as Mahomet upbraids them.' Their scheme of divine government was simple, and like most others formed in the same state of civilisation. One god was supposed to be the supreme ruler; and subject to his sway was a vast multitude of inferior deities. 'The Arabs acknowledged one supreme God, the creator and lord of the universe, whom they called Allah Taala, the most high god; and their other deities, who were subordinate to him, they called simply Al Ilahat, that is, goddesses.* Idols were set up and worshipped; every field, every rivulet, had its divinities. The fixed stars and planets were also exalted into gods, and as such received adoration. Heaven, moreover, was peopled with angels, who, with the wooden, stone, and clay idols on earth, were regularly worshipped. How the Arabians can be supposed believers in a single godhead, under such circumstances, appears extraordinary.

The manner in which these various divinities were rendered propitious, at once marks that no very exalted conception of a divinity existed in the minds of these barbarians. Fasts, pilgrimages, sacrifices, long and unmeaning prayers, were the means employed to obtain the divine favour.

'They are obliged to pray three times a-day (some say seven times a-day): the first, half an hour or less before sunrise, ordering it so, that they may, just as the sun rises, finish eight adorations, each containing three prostrations; the second prayer they end at noon, when the sun begins to decline, in saying which they perform five such adorations as the former; and the same they do the third time, ending just as the sun sets. They fast three times a-year: the first thirty days, the next nine days, and the last seven. They offer many sacrifices, but eat no part thereof, but burn them all. They abstain from beans, garlic, and some other pulse and vegetables.†

'The same rites which are now accomplished by the faithful Mussulman, were invented and practised by the superstition of the idolaters. At an awful distance they cast away their garments; seven times, with hasty steps, they encircled the Caaba, and kissed the black stone; seven times they visited and adored the adjacent mountains; seven times they threw stones into the valley of Mina, and the pilgrimage was achieved as at

the present hour, by a sacrifice of sheep and camels, and the burial of their hair and nails in the consecrated ground.‡"§ The Arabians had many other superstitious practices; they held their women in a degraded condition; and, though refined in some points of manners, they had no written law, were governed despotically by chiefs, and were really barbarians and idolaters. It was the debased religion of this people which Mahomet designed to improve, and we have now to see who this singularly bold and ingenious man was, and how he carried his plans into execution.

Mahomet was born at Mecca, the capital city of Arabia Felix, A.D. 569, during the reign of Noosheervan, surnamed the Just, King of Persia. He was of the family of Haschem, and of the tribe of the Koreish, the noblest in Arabia. His father Abdallah was a younger son of Abdalmotaleb, and dying very young, and in his father's lifetime, left his widow and infant son in very mean circumstances, his whole substance consisting but of five camels and one Ethiopian female slave. Abdalmotaleb was therefore obliged to take charge of his grandchild Mahomet, which he not only did during his life, but at his death enjoined his eldest son, Abu Taleb, who was brother to Abdallah by the same mother, to provide for him for the future. This was very affectionately performed by Abu Taleb, who instructed him in the business of a merchant, which he followed; and to that end he took young Mahomet into Syria when he was but thirteen years old, and afterwards recommended him to Khadijah, a noble and rich widow, for her factor, in whose service he behaved so well, that, by making him her husband, she soon raised him to an equality with the richest in Mecca.

It was after he began, by this advantageous match, to live at his ease, that he formed the scheme of establishing a new religion, or, as he expressed it, of replanting the only true and ancient one professed by Adam, Noah, Abraham, Moses, Jesus, and all the prophets, by destroying the gross idolatry into which the generality of his countrymen had fallen, and weeding out the corruptions and superstitions which the latter Jews and Christians had, as he thought, introduced into their religion, and reducing it to its original purity, which consisted chiefly in the worship of one only God. He hereupon began to affect solitude, usually retiring for a month in the year to a cave in Mount Hara, near Mecca. He had indisputably a very piercing and sagacious intellect, and was thoroughly versed in all the arts of insinuation. The eastern historians describe him to have been a man of an excellent judgment and a happy memory; and these natural parts were improved by a great experience and knowledge of mankind, and the observations he had made in his travels. He is represented as a man of few words, of an equal, cheerful temper, pleasant and familiar in conversation, of inoffensive behaviour towards his friends and acquaintances, and of great condescension towards his inferiors; to all which were joined a comely agreeable person, and a polite address—qualities of no small service in prepossessing those in his favour whom he attempted to persuade.

"When the prophet was about four years old," says Mahmut the Arabian,† "accompanying the sons of his nurse into the field, the blessed child retired into a cave, at the foot of the mountain Uriel, to pray, when the Archangel Gabriel appeared to him, and said, *Bismillar rahmanir rahimi*; that is, 'In the name of God, compassionate and merciful, O child greatly beloved, I am sent to displant from thy heart the root of evil; for thy ejaculations made the gates of Paradise to fly open!' The young resigned one said, 'The will of thy Lord and mine be done.' Then the angel opened his breast with a razor of adamant, and, taking out his heart, squeezed from it the black contagion which was derived from Adam; and having put the child's heart in its place again, he blessed him, and retired to the invisibles.

* Sale, Pre. Disc., p. 20.

* Life of Mahomet—Library of Useful Knowledge.

† Turkish Spy, vol. v. p. 199.

From that time the young favourite of Heaven grew up and prospered in all things, having the smiles of God and man. He was under the tuition of his uncle Abu Taleb, who, discerning the mark of an immense soul in his young nephew, was more solicitous for his welfare than if he had been his son. His fortune being low in the world, he had no other way to provide for his illustrious charge than by placing him as a factor to Khadijah, a widow of the same tribe with Mahomet, which was the noblest among the Arabians."

Mahomet's marriage with Khadijah took place when they were respectively twenty-five years of age; and it was not till twelve years after this marriage that he began to fabricate his imposture, in the cave of Mount Hara, about three miles from Mecca, to which he usually retired during the month of Ramazan, being the time of Lent. At length, A.D. 609, when he was fully forty years old, he disclosed his prophetic mission, at first only to his own wife Khadijah. He told her that the Angel Gabriel had appeared to him in glory, and declared that God had commissioned him as an apostle to reform the world; that he then delivered to him the *Koran* for a divine law, which should complete all antecedent revelations. Khadijah gained for her husband an important proselyte in her uncle Waraka, a Christian, who was well read in the Old and New Testaments. He pronounced Mahomet "to be the great prophet foretold by Moses the son of Amram." It is much more probable that Waraka was the assistant of Mahomet in composing the *Koran* than Sergius the monk, or any other person.

The next proselyte was Abubeker, a rich and respectable inhabitant of Mecca; and his example being followed by many others, Mahomet ventured on a bolder demonstration of his mission. At a numerous assemblage of the Koreishites, at a public entertainment to which he had invited them, he demanded who would become his vizier, or prime minister, assuring them that both happiness in this world and in that to come would accrue to his followers. The guests remained silent in surprise, when Ali, the son of Abu Taleb, a boy about fourteen years of age, started up enthusiastically, and said, "I will be thy vizier, oh Prophet of God! I will break the teeth, pluck out the eyes, rip up the belly, cut off the legs of thine enemies." The joy and approval testified by Mahomet to the zeal of his youthful disciple, was an apt and early specimen what manner of spirit he and his deputy were of. The hostile proceedings and denunciations of the prophet against their idolatry, at length aroused the enmity of the Koreishites; but their threats were despised by him, and, in reply to the prudent remonstrances of his uncle Abu Taleb, he exclaimed, "Though the Koreishites should arm against me the sun and the moon (alluding to the divinities whom they ignorantly worshipped), the one on my right hand, and the other on my left, I would not be shaken from my resolution." He, however, retired for a while to a castle in Mount Safa, and his followers were banished from the city of Mecca. After this persecution, which lasted five years, in the tenth year of his mission (A.D. 618), he sustained a serious loss in the death of his uncle Abu Taleb; and this was followed a short time after by the death of his affectionate wife Khadijah, who had so generously made his fortune. On account of these misfortunes, this year was called the Year of Mourning. Instead of sinking under these adversities, however, upon being violently urged by the Koreishites, who still derided his pretensions, to exhibit some miracle, Mahomet ventured, in the twelfth year of his mission, to publish the revelation of his night visit or journey to the seven heavens.

This event formed a striking epoch in his mission, and displayed in the strongest manner the dexterity as well as boldness of his measures. The question so forcibly put to him of establishing his mission by miracles, is therein artfully parried, and replied to by an appeal to the wonders wrought by Moses, which did not cause the reformation of Pharaoh, and to those of Jesus,

which failed with the Jews; he also incidentally remarked, that miracles were designed rather to strike terror and to punish than to convince.

This famous journey is thus described by Mahomet: While he was in the Caaba, or sacred square building at Mecca, reclining on the sacred stone, the Angel Gabriel came to him; he opened his breast, took out his heart, and washed it in a golden basin full of the water of *faith*, and then restored it to its place. The angel had seventy pairs of wings, and had the beast Alborak with him, on which the prophets used to ride; it was white, and partly horse, ass, and mule, or a middle between the two last, and went as fast as the lightning, which the name Alborak, in Arabic, signifies. When he was brought to Jerusalem by the angel, all the prophets met him, and owned his superiority. He ascended to heaven with the angel, on a ladder of divine light, and left the beast Alborak at Jerusalem till he descended again. He went through seven heavens before he came to the throne of God, which was in the last one, and Gabriel left him at the entrance of it, and waited till he returned from conversing with God, who gave him the offer to be next himself; but he rather chose to descend again to the earth to propagate his religion. His heavens were all 500 years' journey distant from one another. One was of silver, another of gold, another of emeralds, &c., and the last of light. He met some one of the patriarchs or prophets in each of them. In the first he met and discoursed with Adam; in the second, with John the Baptist and Jesus; in the third, with the patriarch Joseph; in the fourth, with Edris or Enoch; in the fifth, with Aaron; in the sixth, with Moses; in the seventh, with Abraham. Thence he was carried up to *Sedrat*, the lotus tree, whence were the sources of the four rivers of Paradise. He saw angels in the likenesses of all creatures in these heavens. He saw a great bull bearing the earth on his horns, and when he shook his head there was an earthquake. There was also a cock, which stood on one heaven, and his head reached another; his voice was heard through heaven and earth, and set all the cocks on earth crowing. He saw an angel of such stature that there was 70,000 days' journey between his eyes. The proportion of a man's height to the distance between his eyes is as seventy-two to one; so that his stature must then have been 14,000 years' journey, four times the height of all his heavens together, in which he was quite out of his mathematics. In the seventh heaven, where God and Christ were, was an angel with 70,000 heads; and in each head 70,000 tongues, with which he praised God. Gabriel accompanied him down from heaven to Jerusalem, and from thence conveyed him, with the beast Alborak, to Mecca; and all this was done in the tenth part of a night. In the conclusion of this extraordinary fabrication, he skilfully adds, that when he was enjoined to repeat fifty prayers each day, he entreated for his nation, and they were finally reduced at his intercession to five. To finish the wonder, he was returned back to the Caaba ere the crier called him to prayers; and "thus," concluded Mahomet, "did I bring with me the prescribed number of prayers, and lessened the burden for my nation."

This story seemed so absurd and incredible, that several of his followers left him on account of it; and it had probably ruined the whole design, had not Abubeker vouched for his veracity, and declared that, if Mahomet affirmed it to be true, he verily believed the whole; which happy incident not only retrieved the prophet's credit, but increased it to such a degree, that he was secure of being able to make his disciples swallow whatever he pleased to impose on them for the future. "And I am apt to think," says Sale, "this fiction, notwithstanding its extravagance, was one of the most artful contrivances Mahomet ever put in practice, and what chiefly contributed to the raising of his reputation to that great height to which it afterwards attained."

In this memorable year twelve citizens of Medina swore allegiance and obedience to the Prophet, whence

they were styled, by way of dignity, *Al Ansar*, that is, "The Defenders;" and the year A.D. 620 was denominated the "accepted year." On Mount Akaba, near Mecca, seventy-three proselytes were soon after added to their number, and swore to defend the prophet from all insult, as they defended their own wives and children. "If," said they to the apostle of God, "we be slain in thy cause, what shall be our reward?" He answered, "Paradise." Then, said they, "Stretch forth thy right hand," and he did so; then they took the oath of obedience, promising rather to die than be perjured. He now established twelve apostles of Islamism, which was the name he gave to his religion, himself being the prime instructor and chief of all the true believers; and he then sent away the Ansars, his followers, and his family, to Medina, for security, and remained behind at Mecca, attended only by Abubeker and his son-in-law Ali.

By the protection which his uncle Abu Taleb had extended to Mahomet, he had been preserved thus far from his enemies; but the charge and dignity of the priest and guardian of the Kaaba, having now, by the death of Abu Taleb, become the post of a member of the family of Ommiyah, a declared enemy to the family of Haschem, to which Mahomet belonged, the Koreishites, irritated and alarmed at the progress making by the new doctrine at Medina, resolved to destroy its author and chief support. This conspiracy was scarce formed, when, by some means or other, it came to Mahomet's knowledge, and he gave out that it was revealed to him by the Angel Gabriel, who had now ordered him to retire to Medina. Whereupon, to amuse his enemies, he directed Ali to lie down in his place, and wrap himself in his green cloak, which he did; and Mahomet escaped miraculously, as they pretend, to Abubeker's house, unperceived by the conspirators, who had already assembled at the prophet's door. They, in the mean time, looking through the crevice, and seeing Ali, whom they took to be Mahomet himself, asleep, continued watching there till morning, when Ali awoke, and they found themselves deceived.

In the recesses of a cave near Mecca, Mahomet and Abubeker eluded for three days the pursuit of their enemies. "There are only two of us," said the apprehensive disciple, when he expected the pursuers to penetrate their retreat. "There is a third, even God himself," said his intrepid chief; "he will defend us." According to tradition, Mahomet afterwards asserted that a miracle was here wrought in his behalf; for that his enemies, approaching the cave, found that its entrance was covered by spiders' webs hanging from the trees, which convinced them that no person had entered it for a long time. After a perilous journey, Mahomet entered Medina in triumph, being enthusiastically received by the Ansars, who disputed for the honour of entertaining the prophet, and took hold of the bridle of his camel. Mahomet then desired them to let her take her own way, for she was a stubborn beast; which she took, accordingly, and stopped at the stable of two rich orphans, Sahali and Sohaili, where the prophet dismounted. This spot he purchased from the orphans, after refusing their offer to bestow it upon him, and Abubeker paid the money. He erected thereon a mosque, and a habitation for himself, on which he laboured with his own hands. Medina henceforth received the august title of *Medinat al Nabi*, or the "City of the Prophet."

The Mahometan era, called the Hejira, takes its commencement from the date of Mahomet's flight from Mecca to Medina. The generality of writers place this epoch on Friday the 16th of July, A.D. 622. It is this event which has rendered Friday the solemn day of the week for his followers; this choice also agreeing with the customs of the Arabians, who held their assemblies usually on the Fridays. The word *Hejira* is derived from the Arabic verb *Hajara*, to abandon one's native country, to emigrate on account of persecution; which comes from the Hebrew *Hagar*, the stranger or emigrant, the name of Ishmael's mother.

It was from this period that Mahomet, having fully ascertained the hate of his enemies and the extent of his own power, proceeded to lay aside the arts of persuasion and patient endurance, whereby he had hitherto sought to propagate his tenets; and, elated by the devotion of his disciples and his reception at Medina, he framed henceforth the revelations of the Koran in a tone which proclaimed him a persecutor, and empowered his followers to make war against all opposers. The successful battle of Beder followed soon after; and he then made known those doctrines which have rendered the arms of the Mussulmans so formidable, namely, "that no one can escape his destiny; inasmuch as the man whose days are not complete will escape unhurt from a shower of arrows, when he whose fatal term has arrived cannot escape death by any precaution whatsoever." The second incentive is that which the present occasion furnished him with:—"The sword," exclaimed the prophet, "is the key of heaven and of hell; a drop of blood shed in the cause of God, a night spent under arms, is of more avail than two months of fasting and prayer. Whosoever falls in battle, his sins are forgiven: at the day of judgment, his wounds shall be resplendent as vermilion and odoriferous as musk; the loss of his limbs shall be replaced by the wings of angels and of cherubim."

This victory, the first of Mahomet's battles, was gained, in the second year of the Hejira, over the idolatrous Meccans, headed by Abu Sofian, in the valley of Beder, which is situated near the sea, between Mecca and Medina. Mahomet's forces consisted of no more than 319 men, and the enemy's army of near 1000; notwithstanding which odds, he put them to flight, having killed seventy of the principal Koreish, and taken as many prisoners, with the loss of only fourteen of his own men. This first victory, although it may seem no very considerable action, was yet of great advantage to him, and the foundation of all his future power and success; for which reason it is very famous in Mahometan history, and is frequently vaunted of in the Koran as an effect of the divine assistance, through the miraculous interposition of the Angel Gabriel. The gaining of the battle was, however, wholly attributable to the extraordinary stratagem of Mahomet, by his expedient, at the critical moment, of scattering a handful of dust against his enemies, at the same time exclaiming, "Let their faces be confounded!"—which action so invigorated his fainting followers, that they charged and overthrew their foes. Mahomet captured the whole caravan, which consisted of 1000 camels, richly laden, from Syria; and this afforded him the means of rewarding his followers, and inciting them to further exertion by the allurements of wealth and the hope of plunder.

Some reckon as many as twenty-seven expeditions wherein Mahomet was personally present, in nine of which he gave battle; besides several other expeditions, undertaken by his orders, in which he was not present. His forces he maintained partly by the contributions of his followers for this purpose, which he called by the name of *zacaat*, or alms, and the paying of which he very artfully made one main article of his religion; and partly by ordering a fifth part of the plunder to be brought into the public treasury for that purpose, in which matter he likewise pretended to act by the divine direction.

In a few years, by the success of his arms, he considerably raised his prophetic character and power. In the sixth year of the Hejira, he set out with 1400 men to visit the temple of Mecca, not with any intention of committing hostilities, but in a peaceable manner. However, when he came to Al Hodeibiya, which is situated partly within and partly without the sacred territory, the Koreish sent to let him know that they would not permit him to enter Mecca unless he forced his way; whereupon he called his troops about him, and they all took a solemn oath of fealty or homage to him, and he resolved to attack the city; but those of Mecca, sending Arwa Ebn Masud, prince of the tribe of Thakif, as their ambassador, to desire peace, a truce

was concluded between them for ten years, by which any person was allowed to enter into league either with Mahomet or with the Koreish, as he thought fit.

Having subdued the chief part of the pagan tribes, and by his relentless severity exterminated the Jewish classes who dwelt peaceably in Arabia, in the seventh year of the Hejira (A.D. 628), he assumed the state of a sovereign, and sent embassies to the neighbouring monarchs, exhorting them to embrace Islamism.

In the eighth year of the Hejira, a quarrel, real or feigned, gave him the opportunity of possessing himself of Mecca, and of the sacred square edifice called the Caaba. Mahomet appearing suddenly at their gates with 10,000 men, before the troops of Mecca had even been apprised of his departure from Medina, they had no choice left but an immediate surrender or destruction. Thus pressed, and menaced with instant death, the Koreish submitted to the superior power of Mahomet. Their final submission to him, and their acceptance of his faith, were ratified subsequently on the hill El Safa. Having visited the holy building of the Caaba, and broken in pieces the idols wherewith it was encircled, Mahomet went in procession seven times round the building, and touched respectfully the black stone which was held sacred by the Arabs; then entering the edifice, he repeated the formula, "*God is great.*" Afterwards he went to the well Zemzem—which is believed by them to be the same that the angel showed to Hagar—drank of the water, and performed the required ablution. Artfully blending attention to exterior observances with zeal, and pursuing a mixed system of mercy and rigour, he subdued the hearts of his high-minded countrymen, and soon superadded to his claims of power the more imposing and indissoluble bonds of superstitious reverence and awe. The capture of Mecca, and the submission of the powerful race of the Koreish, was soon followed by the conversion to Islamism of most of the remoter pagan tribes, until all Arabia bowed the neck beneath his yoke.

Mahomet, having thus become master of all Arabia, made great preparations for the conquest of Syria; but this vast enterprise was reserved for his successors. He gradually, however, paved the way for their successes, and brought the celebrated region of Arabia into one complete and powerful union. He established the law which still obtains in all the Mussulman states, of imposing a personal tax on such subjects as do not embrace Islamism. By this custom, still subsisting among all the sovereigns who acknowledge the Koran, every reputed infidel pays a *kharaj*, or capitation-tax, over and above the imposts which he supports equally with the rest of the subjects. He absolutely prohibited all idolators from making the pilgrimage to Mecca, or any foreigner from entering the Caaba, under pain of death. These were strokes of profound policy. He retained the pilgrimage to Mecca, which had been of ancient standing among the descendants of Abraham and Ishmael. Though he destroyed the images used at Mecca as objects of idolatrous worship, he carefully retained the holy relics of the black stone and the supposed impression of Abraham's foot. The black stone had been immemorially venerated there; the angels, it was said, had brought it *white* to the Caaba, and the sins of mankind had transformed it to *black*. Hence, in allusion to this stone, the Orientals use the compliments, "May God whiten thy face;" "May the shah make thy face white," &c.

These practices no less forwarded the progress of Islamism than did the sword of Mahomet. Every where the petty Arabian tribes overthrew their idols and submitted themselves to the new faith. Thus was Mahometanism established, and idolatry rooted out, even in Mahomet's lifetime, throughout all Arabia; and the Arabs, being then united in one faith and under one prince, found themselves in a condition for making those conquests which extended the Mahometan faith over so great a part of the world.

In the tenth year of the Hejira (A.D. 631), Mahomet set forth on a solemn and pompous embassy to Mecca,

accompanied by all his wives, and by at least 90,000 pilgrims. He sacrificed with his own hands sixty-three victims, and liberated sixty-three slaves, in thanksgiving for each year of his life; he shaved his head, and scattered the hair amongst the multitude, who eagerly seized portions of it as sacred relics. He closed the solemnity with the following apostrophe, which, as if pronounced from heaven, concludes the Koran:—"Henceforth, wretched and miserable shall they be who deny your religion. Fear not them, but fear me; this day I have perfected your religion, and completed my grace toward you. I have willed that Islamism be your religion." He established the lunar moveable year, still in use with the Mahometans; and, finally, as supreme Pontiff, or Imam, dismissed the people with a farewell, the last, as he declared, that he should give them; whence this pilgrimage derived its name of the Farewell.

Mahomet, having returned to Medina, now drew near the close of his extraordinary and fortunate career. His health had been for three years on the decline; but he had neither relaxed his duties nor his labours. Being at length affected with a mortal malady, he was conveyed to the house of his favourite wife, Ayesha, where he expired, in the eleventh year of the Hejira (A.D. 632), in the sixty-first year of his age. Of all his wives, the first alone bore him any children, of whom only his daughter Fatima, wife of Ali, survived him.

Having thus presented a sketch of the life of this remarkable man, we proceed to a notice of the religion which he founded. As already mentioned, Mahomet must be viewed chiefly in the light of an improver on the old modes of belief and practice of the Arabians; and his merit (if we may so call it) in this respect appears to have been the combining of a variety of religious opinions into one form of faith, superadding an implicit belief in his own prophetic character, and enunciating the whole of his code in the writings of the Koran. At the period of his death, he bore the character both of a divinely appointed vicegerent and of a secular prince, the latter being gained by his conquests; and his successors claimed the same double qualification. After the prophet's decease, the election of a successor occasioned considerable excitement, his father-in-law Abubeker, and his son-in-law and cousin Ali, each claiming the office of caliph. Abubeker was finally successful in the competition, and he, as is known to the readers of history, was succeeded by the ferocious Omar. Ali became the fourth caliph, but he was summarily cut off by poison; and from the long contests which afterwards occurred, it is difficult to say in what line the caliphate was ultimately settled.

The Koran, or prescribed record of the Mahometan faith, consists of 114 chapters, each with a distinct title, but varying in length from a few sentences to several pages. No continuous subject can be said to run through the work, each chapter being in the form either of a separate revelation, or treating of a peculiar matter in faith, morals, or law. Among the titles to the various chapters, we find the following:—The Cow; the Family of Imran; Women; the Spoils; Jonas; Joseph; Abraham; The Night Journey; The Cave; The Assembly; The News; Divorce; The Fig; The Resurrection, &c. The whole is a singular jumble of highly poetical passages, narratives characterised by great simplicity and beauty of style, garbled extracts from the Old Testament, and pious exclamations. The praise of the Almighty is a prevailing theme in all parts of the work, along with a deep inculcation of the principle that Mahomet is the greatest of all prophets who ever appeared on earth. The work certainly contains much that is excellent as respects moral admonition, but also a great deal that is incomprehensible and ludicrous. Mahomet did not live to complete his Koran in the shape we now see it. With the assistance, unquestionably, of a person versant in the Jewish Scriptures, he from time to time, as was suggested by passing circumstances, composed his fragments, which he declared to have been revealed to him from God by the

Angel Gabriel; and these having been collected by his followers, were, by succeeding caliphs, formed into a volume entitled *Al Koran* (pronounced *Kooraan*), or *The Book*.

Whatever we may advance against the authority of the Koran, it is certain that it has been received by Mahometans with a degree of reverence rarely witnessed among Christians towards the Holy Scriptures. In it they view the whole code of religious belief, civil law, and moral obligation. The belief which they generally profess, as drawn from the Koran, consists in the following leading points:—Religion is divided into two branches—faith and practice. Faith includes belief in God, in his angels, his revelations in the Koran, his prophets, the resurrection and day of judgment, and God's absolute decrees. Practice includes prayer, comprehending under this head the purifications necessary before prayer, alms-giving, fastings, and the pilgrimage to Mecca. The religion, as a whole, is called the religion of *Islam*, or *Islamism*. "The word *islam* signifies an entire submission to the will of God, and thence the attaining of security, peace, and salvation. This act is performed, and these blessings are obtained, according to the doctrine of the Koran, by acknowledging the unity of God and the apostleship of Mahomet. Every man who makes this profession (*aslama*) is a *Moslem*, that is, one who has entirely given himself up to the will of God, and is, on that account, in a state of salvation (*salam*). As it happens that *Muslimani*, the dual of *Muslim*, is commonly substituted for the singular by the Persians and Turks, the words *Mussulman* or *Muslimans*, has in those, as well as in European languages, now nearly superseded the shorter and more correct term."—(*Encyclopedia Americana*).

The notions of God and his attributes appear from the Koran to be just, and favourable to devotion. The belief in angels is, however, mingled with many singular fancies. They are believed to have been created of fire, to have pure and subtle bodies requiring no support, and that there is no distinction of sexes among them. The angels are supposed to have various forms and offices assigned to them; some adoring God, singing praises to him, or interceding for mankind, while others are engaged in writing down the actions of men, carrying the throne of God, and performing other services. The Mahometans also believe that there are two guardian angels appointed to attend upon every human being, who observe and write down his actions, and who are changed every day.

There are four angels whom the Mahometans believe to be more in the favour of God than any of the others. These are Gabriel, who is sometimes called the Holy Spirit and the Angel of Revelations, from his being employed in writing down the decrees of God; Michael, the friend and protector of the Jews; Azrael, the angel of death; and Israil, who is to sound the trumpet at the resurrection. The devil, called in the Koran *Eblis*, is supposed to have been one of those favoured angels, but he fell, because he refused to worship Adam, with the other angels, at his creation. In the eighteenth chapter of the Koran, however, he is said to have been one of the *genii*, a species of beings whom the Mahometans believe to be intermediate between angels and devils. The *genii* are said to have been created, like the angels, of fire, free from smoke; but, unlike the angels, they eat and drink, propagate their species, and are subject to death. Some are supposed to be good, and others bad. In the seventy-second chapter of the Koran, a company of the *genii* are described as believing in the doctrine of Mahomet, on hearing him read it.

With respect to the belief in prophets, the Koran inculcates the doctrine that God has at various times given revelations of his will to several prophets, whose books originally amounted to one hundred and four. Of these, ten were given to Adam, fifty to Seth, thirty to Enoch, ten to Abraham, and the other four to Moses, David, Jesus, and Mahomet. All these, except the four last, they believe to be lost; and that, after Mahomet, no other revelation may be expected. It

appears that they have some prayers of Moses, Jonas, and others, a book called the *Psalms*, which consists of extracts from our version mixed up with other matter, and a history of Christ, said to be written by St Barnabas. In this book, Christ is made to predict the coming of Mahomet under the title of "Famous," that being the signification of his name in Arabic. According to tradition, there have been from time to time no fewer than 224,000 prophets sent into the world; and of these, 313 were apostles, charged with commissions to reclaim mankind from the infidelity into which they had fallen. Six of them, namely, Adam, Noah, Abraham, Moses, Jesus, and Mahomet, were sent especially to promulgate new laws or dispensations. The Mahometans believe some of these apostles to have been superior to the others; to the last six, for instance, they give the first place. They believe them to have been free from great sins, although not perfectly pure, and that they all professed the same religion. In this list of prophets they introduce many whose names are mentioned in scripture as patriarchs, such as Adam, Seth, Lot, &c., and also many others who are not mentioned in the sacred writings. But of all the prophets of God, the Koran enforces the leading doctrine that Mahomet is the greatest, and that his mission is to be believed in, under the most severe penalties. "God will render of non effect the works of those who believe not, and who turn away men from the way of God: but as to those who believe and work righteousness, and believe in the revelation which hath been sent down unto Mahomet (for it is the truth from their Lord), he will expiate their evil deeds from them, and will dispose their heart aright. When ye encounter the unbelievers, strike off their heads, until ye have made a great slaughter among them; and bind them in bonds: and either give them a free dismission afterwards, or exact a ransom, until the warriors shall have laid down their arms. This shall ye do."—Chap. xlvii. From numerous passages of this kind, the Mahometans have framed the brief enunciation of their belief—"There is no God but God, and Mahomet is his prophet," a saying which is ever in their mouths, and may be called their popular creed.

Regarding the resurrection, the Mahometans believe that, when a dead person is laid in the grave, he is received by an angel, who gives him notice of the coming of the two *Examiners*. These are two black angels, of a terrible appearance, named Mouker and Nakir. They order the dead person to sit upright, and examine him concerning his faith in the unity of God and the mission of Mahomet. If he answer correctly, his body is allowed to lie at rest, and is refreshed with the air of paradise; but if he appear sceptical, they beat him on the temples with iron rods, till he cries with anguish so loud as to be heard by all except men and *genii*. As to where the soul dwells after death, the Mahometans seem to have a variety of opinions, which need not be particularised. Mahometans are also divided as to the nature of the resurrection, some believing that it will be merely spiritual, others that the body only will be raised; but it is believed that all who have ever lived will appear for judgment. It is likewise believed that the irrational animals will be judged at the resurrection, and weak animals will take vengeance on the strong until satisfaction is given to the injured. The Koran enjoins kindness to all animals whatsoever, although it pronounces some to be unclean; and it is allowed that the conduct of Mahometans in this respect far excels that of the generality of Christians.

It is supposed by the more orthodox Mahometans, that the books wherein the bad actions of a man are registered will be put into one scale, and the good into another, and according as these preponderate, sentence will be given. After this will follow the satisfaction which every one takes of his fellow, or the retaliation made by them for the injuries they have received. The manner of giving this satisfaction will be to take away from one man a portion of his good works and give it to one whom he has injured. "Which being done,"

says Mr Sale, "if the angels say, Lord, we have given to every one his due, and there remaineth of this person's good works so much as equalleth the weight of an ant, God will of his mercy cause it to be doubled to him, that he may be admitted into paradise. If, on the contrary, his good works be exhausted, and there still be some to receive satisfaction from him, God will order an equal amount of their sins to be heaped upon him, that he may be punished in their stead. The trials being over and the assembly dissolved, the Mahometans hold that those who are to be admitted into paradise will take the right-hand way, and those who are destined for hell-fire the left; but both of them must first pass the bridge called in Arabic *al Sirat*, which they say is laid over the midst of hell, and describe to be finer than a hair and sharper than the edge of a sword."

The Mahometans believe hell to be divided into seven apartments, designed for the reception of different degrees of sinners. The first is destined to receive the wicked Mahometans, the second for the Jews, the third for the Christians, and the rest for other sects and unbelievers. Over these will be placed nineteen angels, to whom the condemned will confess the justness of God's sentence, and beg them to intercede with him in their behalf. The punishment of infidels will be continued for ever, but wicked Mahometans will be released after a certain period of suffering.

Before entering paradise, the righteous will drink at the pond of Mahomet, which is supplied with water from the rivers of paradise. It is described as a month's journey in compass, and whoever drinks of the water will thirst no more. It is a matter of keen dispute whether paradise is already created, many supposing that it will be different from the paradise in which Adam was placed. The more orthodox opinion, however, is, that it is the same, and that it was created before the world. It is supposed to be situated above the seven heavens, immediately under the throne of God, and is described as a place of great beauty. The trunks of the trees are of gold, one of which, the tree of happiness, will yield all sorts of fruit for the consumption of true believers.

God's absolute decree and predestination of both good and evil, is a doctrine which Mahomet always took occasion to impress upon his followers. He said that God had not only predetermined the adverse or prosperous fortune of every person in the world, but also his faith or infidelity, which fate it is impossible by any foresight to avoid. By this doctrine, Mahomet taught his followers to have the greatest contempt for danger, which was of material service to him in the propagation of his creed.

Of the four points of religious practice required by the Koran, prayer is the first. Mahomet included under this act purifications of the body, by total immersion at certain periods, and by washing the face, hands, and feet, at others. To make his followers punctual in the observance of these purifications, Mahomet declared that the practice of religion is founded on cleanliness, without which prayer would not be heard by God. A Mahometan is obliged to pray five times in the twenty-four hours, at stated periods—before sunrise in the morning, when noon is past, in the afternoon before sunset, in the evening after sunset, and before the first watch of the night. Public notice is given of these periods by the *muezzins*, or criers, and every Mahometan prepares himself for prayer. This he performs either in the mosque, or any other place, providing it be clean, after a prescribed form, and with a certain number of ejaculations, which he is on no occasion to abridge, unless when on a journey or preparing for battle. It is also necessary that he should kneel in a humble posture, and turn his face towards Mecca, as expressed in the second chapter of the Koran: "Turn, therefore, thy face towards the holy temple of Mecca, and wherever ye be, turn your faces towards that place." The direction of Mecca is pointed out within the mosque by a niche on the outside, by the

situation of the doors and the steeple; and tables have been calculated for finding this out when they have no other guide. A Mahometan is also obliged to lay off all costly parts of his dress before prayers, that he may not appear proud. Females are not allowed to enter the mosques along with the men, but they may visit them at other periods.

The prayers of the Mahometans consist chiefly of pious exclamations, praising the greatness and goodness of God; and one of the more common of these prayers consists in a repetition of the first chapter of the Koran, called the *Fathat*, or Belief. It is in these words: "Praise be to God, the Lord of all creatures; the most merciful, the King of the Day of Judgment. Thee do we worship, and of Thee do we beg assistance. Direct us in the right way, in the way of those to whom Thou hast been gracious; not of those against whom Thou art incensed, nor of those who go astray."

Alms-giving is a necessary part of the religious practice of Mahometans. These consist of cattle, money, corn, fruits, and wares which can be sold. At the end of the fast of the Ramadan, every Mahometan is obliged to give in alms, for himself and for every one of his family, a measure of wheat, barley, dates, raisins, rice, or other provisions. "The legal alms," says Mr Sale, "were at first collected by Mahomet himself, who employed them as he thought fit in the relief of his poor relations and followers, but chiefly applied them to the maintenance of those who served in his wars, and fought, as he termed it, in the way of God. His successors continued to do the same, till, in process of time, other taxes and tributes being imposed for the support of the government, they seem to have been weary of acting as almoners to their subjects, and to have left the paying of them to their consciences."

Fasting is the third point of religious practice amongst the Mahometans. It consists in abstaining from satisfying the appetites; in restraining the ears, eyes, tongue, hands, feet, and other members, from sin, and the fasting of the heart from worldly cares, and thinking of nothing but God. During the month of the Ramadan, Mahometans are obliged to fast from the time the new moon first appears till the appearance of the next new moon. In this month they abstain from eating and drinking from daybreak till sunset; and this injunction they observe so strictly, that while they fast, they suffer nothing to enter their mouths or the other parts of the body, esteeming the fast broken if they smell perfumes, bathe, or even purposely swallow their spittle. The old and the sick are exempted from this fast; but in the case of the latter, when they recover, they must fast the same number of days. After sunset the people are allowed to refresh themselves—to eat, drink, and enjoy the company of their wives till daybreak. The more rigid, however, commence the fast again at midnight.

According to the injunctions of the Koran, every man is to perform a pilgrimage to Mecca once in his life, except prevented by poverty or ill health. It is clear that such an observance is altogether inapplicable to the condition and situation of the great bulk of the human race; and what is impossible in human practice, can never have been enjoined by the Creator. Mahomet, it is evident, only thought of Arabia and its neighbourhood, when he planned this idle ceremonial observance. Aware that, even within that limited district, his followers would have a difficulty in performing such a pilgrimage, he allows any one who is wealthy enough, to hire and send a deputy; many, we are informed, neglect this duty who cannot plead a lawful excuse. The temple of Mecca stands in the midst of the city, and is called the sacred or inviolable temple. Within it are said to be the tomb of Ishmael, and a remarkable black stone, which bears the mark of Abraham's foot. This temple was held in great veneration by the Arabians long before the time of Mahomet; some even say that it was built by Adam immediately after his expulsion from paradise. To this place pilgrimages are made from all parts where the Mahometan religion is

professed. A number having collected from any particular district, form themselves into a caravan for the purpose of mutual protection, which is very necessary from the number of robbers who infest the route. The pilgrims meet at different places around Mecca, according to the direction in which they have come, and are obliged to be there by the beginning of the first month, called Dhulhajja.

"It is not," says Mr Lane, "by the visit to Mecca, and the performance of the ceremonies of circuiting the temple seven times, and kissing the black stone in each round, and other rites in the holy city, that the Moslem acquires the title of the *hadji* (pilgrim). The final object of the pilgrimage is Mount Arafat, six hours' journey from Mecca. During his performance of the required ceremonies at Mecca, and also during his sojourn at Arafat, and until his completion of the pilgrimage, the Moslem wears a peculiar dress called *ehhram*, generally consisting of two simple pieces of cotton, or linen, or woollen cloth, without seam or ornament, one of which is wrapped round the loins, and the other over the shoulders; the instep and heel of each foot, and the head, must be bare; but umbrellas are now used by many of the pilgrims. It is necessary that the pilgrim should be present on the occasion of a Khootbeh, which is recited on Mount Arafat in the afternoon of the 9th of the month Dhulhajji. In the ensuing evening, after sunset, the pilgrims commence their return to Mecca. Halting the following day in the valley of Mina, or Moona, they complete the ceremonies of the pilgrimage by a sacrifice (of one or more male sheep, he-goats, cows, or she-camels, part of the flesh of which they eat, and part give to the poor), and by shaving the head and clipping the nails. Every one after this resumes his dress, or puts on a new one, if provided with such. The sacrifice is called *el fida* (or the ransom), as it is performed in commemoration of the ransom of Ishmael by the sacrifice of the ram, when he was himself about to have been offered up by his father; for it is the general opinion of Mahometans, that it was this son and not Isaac who was to have been sacrificed by his father."

The laws by which Mahometans are governed are in a great measure derived from the Koran. Where this sacred book is silent, reference is made to the traditions of the prophet to direct the decisions of the judge. Regarding the Koran as a book of jurisprudence, we quote the following from the Library of Useful Knowledge:—"Nothing but the prejudices of education could make a reasonable man look upon the Koran as a book of jurisprudence capable of conveying instruction to any but a nation of savages. Deficient in form, deficient in clearness, incomplete, it possesses not one single quality requisite to a body of law. In the midst of a vast farrago of nonsense, hidden amidst unmeaning explanations and dark mysterious prophecies, there sometimes appears a command respecting the distribution of property or the punishment of offenders. But no explanations are given—no regular description of the means by which property may be acquired; no enumeration of those by which the rights to it may be lost, is even attempted. The rights of individuals, in their several capacities, to the services of others, are nowhere distinctly mentioned; nor is there any the most distant approximation to a systematic view of the several obligations to which it was intended to subject the members of the community. As occasion prompted, or when a dispute happened, Mahomet was accustomed to issue a revelation, which answered for the immediate purpose. But the original unwritten customs of the Arabs remained in full force, receiving little modification from the decrees of the prophet. One advantage, and one alone, he may be supposed to have originated—his were *written* decrees; it was a commencement for a body of laws, though a rude and imperfect one. This benefit, however, is more than counterbalanced by the evil of their being irrevocable. What the ignorant barbarian instituted, succeeding generations have been obliged to retain. No matter how absurd, how injurious the decree, religion commands the faithful Moslem to abide

by it. The Almighty was its author, and he is all-wise; and, moreover, is as wise at one time as another. How, then, shall we pretend to amend the divine ordination, or fancy that he himself need amend it? The conclusion is irresistible, provided the premises be allowed. The nations who have assumed the Moslem faith have consequently remained, and, while professing it, will remain, barbarians."

One of the worst features of the Mahometan faith is the degraded position which it assigns to women. This, indeed, forms a radical error in the constitution of society in Mahometan countries, and must be removed before there can be a steady advance in rational improvement. Women are considered in every respect inferior to men. Few of them, even among the highest classes, receive any instruction; they are carefully secluded from public observation; assigned in marriage without their own consent, on payment of a trifling sum in form of dowry; and are divorced at pleasure—all which tends to debase their minds, and to produce the worst kind of social vices. Polygamy and legal concubinage add to the evils caused by such practices. The Koran allows a man to marry four wives, and to maintain as many concubine slaves as he may choose. He may divorce any of his wives at any instant which caprice or passion may suggest, merely by uttering the emphatic words, "Thou art divorced!" and she must return to her parents or friends accordingly. He may take her again as a wife, and again divorce her; and even divorce her a third time, provided she has in the interval been married to and divorced from another man. Mr Lane, in his work on Egypt, says, that he has known cases in which men have, in the course of a few years, married as many as twenty or thirty wives; and also cases of women who had been married to a dozen or more men successively. In most instances, we are told, a man marries no more than one wife; but as these practices are common, we can easily judge of the depravity of manners which prevails in those countries professing the Mahometan creed.

From the manner in which females are treated, it has been generally supposed by Christians that the Mahometans believe that women have no souls. But this is a mistake. Women are believed to have souls, and are not to be excluded from paradise, though they are there to perform offices of a subservient nature. The meanest person in paradise, it is believed, "is to have eighty thousand servants, and seventy-two wives of the girls of paradise, besides the wives he had in this world; that he is to inhabit a tent composed of pearls, iacinths, and emeralds; at meals he will be served in dishes of gold; and he is to be at liberty to drink freely of the wine of paradise, which will not intoxicate." In such promises of felicity, we have a striking proof of the mean ideas of eternal happiness formed by the prophet, as well as of his knowledge of mankind.

The Koran forbids the use of wine or any intoxicating liquors; and this is among the best injunctions which it contains. Opium and other inebriating drugs are understood to fall within the line of prohibition, though not mentioned. The use, therefore, of either intoxicating drinks or drugs, is considered immoral in all Mahometan countries. Mussulmans of all ranks are remarkable for their sobriety and temperance in food. The eating of swine's flesh is strictly prohibited; and, indeed, most animals forbidden to be eaten by the Mosaic law are alike forbidden by that of Mahomet. All animals used for food must be killed by cutting their throat; and, in performing the operation, the butcher must say, "In the name of God! God is most great!" Gambling is also prohibited; also usury, and the making of any images or pictorial resemblances of any thing that has life. Perhaps the desire to extinguish idolatry influenced the prophet in laying down the last-mentioned law. Apostacy from Islamism is deemed a most heinous sin, and must be punished with death.

The Mahometan creed enjoins no sabbath, like that of either the Jews or Christians, but selects Friday as a day in the week to be distinguished by more than

usual solemnity of devotion. Friday has been pitched upon, because it is said Adam was created on that day, and because the resurrection is prophesied to be on that day of the week. Perhaps a desire to avoid Saturday or Sunday, the days revered respectively by Jews and Christians, may also have influenced its adoption. Friday is called *El-Goomah*, or The Assembly; and on the forenoon of that day large congregations assemble in the mosques, when, in addition to the usual prayers, a sermon or address is delivered, and lessons read from the Koran, by the officiating imams. After prayers, all kinds of work go on as usual.

All religions, above the meanest paganism, have possessed a body of priests, or functionaries to whom the knowledge of the faith was confided, and by whom its precepts were enforced. Considering that Mahomet must have been conversant with the constitution and import of the Jewish priesthood, as laid down in the Levitical law, and also acquainted with the arrangements of the Christian church, it is remarkable that he instituted no order of clergy, but, on the contrary, left his religion to be professed by the people at large, without any distinction as to rank or qualification. On this account, Mahometanism has no priesthood, and cannot be said to constitute in any country what we understand by the term church. Wherever it is established as the religion of the community, *mosques* or chapels have been erected, generally by endowments from wealthy individuals; and these are individually under the charge of a warden, who is custodian of the revenues, and appoints the ministers of religion and inferior servants. "Two imams are employed to officiate in each of the larger mosques: one of them, called the *khateeb*, preaches and prays before the congregation on the Friday; the other is an *imam ratib*, or ordinary imam, who recites the five prayers of every day in the mosque, at the head of those persons who may be there at the exact times of those prayers: but in most of the smaller mosques both these offices are performed by one imam. There are also to each mosque one or more *muezzins* (to chant the call to prayer) and *bouwabs* (or doorkeepers); and several other servants are employed to sweep the mosque, spread the mats, light the lamps, and attend the water-wheel by which the tank or fountain, and other receptacles for water, necessary to the performance of ablutions, are supplied. The imams, and those persons who perform the lower offices, are all paid from the funds of the mosque, and not by any contributions exacted from the people. The condition of the imams is very different, in most respects, from that of Christian priests. They have no authority above other persons, and do not enjoy any respect but what their reputed piety and learning may obtain them: nor are they a distinct order of men set apart for religious offices, like our clergy, and composing an indissoluble fraternity; for a man who has acted as imam to a mosque may be displaced by the warden of that mosque, and, with his employment and salary, loses the title of imam, and has no better chance of being again chosen for a religious minister than any other person competent to perform the office. The imams obtain their livelihood chiefly by other means than the service of the mosque, as their salaries are very small, that of a *khateeb* being generally about a piastre (nearly 2½d. of our money) per month."—(*Lane's Egypt*.)

"The Mahometans," continues the same authority, "observe the utmost decorum in their public worship. Their looks and behaviour in the mosque are not those of enthusiastic devotion, but of calm and modest piety. Never are they guilty of a designedly irregular word or action during their prayers. The pride and fanaticism which they exhibit in common life, in intercourse with persons of their own or of a different faith, seem to be dropped on their entering the mosque, and they appear wholly absorbed in the adoration of their Creator."

Mahometans have an extreme reverence for a green colour, which is used exclusively as the hue of turbans

or other garments by those who claim hereditary descent from the family of the prophet. Europeans generally imagine the crescent to be a common symbol of Mahometanism, as the cross is of Christianity; but we believe this is founded on mistake. The crescent, from a very early period of history, was a heraldic ensign of Byzantium or Constantinople, and has been appropriated by the Turks since their capture of that city.

The Mahometans are generally affected with the most superstitious reverence for imaginary saints and "favourites of God." They imagine that idiots and lunatics are under the immediate inspiration of Heaven; and, unless these be dangerously mischievous, they are permitted all sorts of license. "Most of the reputed saints of Egypt," says Mr Lane, "are either lunatics idiots, or impostors." Any one who is deranged by religious excitement becomes a *uelee*, or an especial favourite of the Almighty, and is supposed to be gifted with supernatural powers. Almost every celebrated saint, deceased, is honoured by an anniversary birthday festival; and on occasion of these festivals, many persons visit the tomb of the saint, both as a duty and as a supposed means of obtaining a special blessing. Besides the various classes of saints, there are different orders of *durweeshes*, or dervises, some of whom subsist by begging, and others by performing at religious festivals; a few devote themselves to religious seclusion, and gain a character for exalted piety.

Mahometanism, from shortly after the death of its founder, has been divided into two great parties or sects, who split upon the disputes concerning the Caliphate, or spiritual and civil supremacy, and received the name of *Sunnites* and *Shiites*. The Sunnites take their appellation from the *Sunna*, or collections of traditions relating to Islamism, which they believe to be of equal importance with the Koran. The term *Shiites* signifies heretics, which they are called by the opposite party from their misbelief. The adherents of the doctrine that Ali, son-in-law of Mahomet, was properly his successor, reject the *Sunna*. The Turks are Sunnites, and the Persians are Shiites, and each hates the other with implacable animosity. The Sunnites, we believe, are reckoned the orthodox sect, and acknowledge the reigning sultan as the true successor of Mahomet.

Besides differing as to the credibility of the *Sunna* and the successorship of the prophet, the Mahometan world is divided into four minor sects, the *Hanafees*, *Shafees*, *Malikees*, and *Hamblees*, being so called from the respective doctors whose tenets they have adopted. "The Turks," says Mr Lane, "are of the first sect, which is the most reasonable." About the middle of last century a great schism, or attempt at reformation, broke out in Arabia, headed by Mohamed, son of Abdel Wahab, a pious and learned sheikh. Young Mohamed claimed divine inspiration, and taught, like the Koran, (the doctrines of which he but partially received), the existence of an only God, the Creator of the world, the rewarder of the good and the punisher of the bad; but he rejected all the stories contained in the Koran, especially those concerning Mahomet, whom he considered merely a man beloved of God, but branded the worship of him as a crime directly opposed to the true adoration of the Deity. He also condemned the ornaments and splendour which are found in the mosques and the sepulchres of pretended saints. In short, he stripped Mahometanism of all its trappings, and reduced it to little else than a pure Theism. All who should oppose this new doctrine were to be destroyed by fire and sword. His doctrines, being adopted by some influential chiefs, spread with wonderful celerity, and the *Wahabees*, as his followers were called, shook the stability of the empire of the Turks in Asia. After a hot war of many years, the Wahabees were suppressed by Mehemet Ali, the present Pasha of Egypt; but their doctrines are still far from being exterminated.

SUPERSTITIONS.

MANKIND have in all ages been prone to the most lamentable superstitions. The enlightened nations of antiquity were no more exempted from them than the most ignorant. The Jews, as we are repeatedly informed in Scripture, could with difficulty be restrained from idolatrous and superstitious practices, and confined to the worship and service of the only true God. This remarkable tendency of the Hebrew nation was in all likelihood caused by their sojourn for the space of four hundred years among the Egyptians, whose whole system of religion was a mass of idolatrous observances. They had a number of ideal gods to whom they erected temples of prodigious size and architectural splendour; the principal of these deities were Osiris and Isis, which are thought to have been typical of the sun and moon. But they also offered worship to various animals, as the ox or bull (hence the golden calf of the Hebrews), to which they gave the name of Apis; the dog, the wolf, the hawk, the ibis or stork, the cat, and other creatures; they likewise paid adoration to the Nile, personifying it in the crocodile, to which temples were erected, and priests set apart for its service. The Egyptians, notwithstanding their learning, also believed in dreams, lucky and unlucky days, omens, charms, and magic. In a word, they were grossly superstitious, and seem to have had but a feeble conception, if any, of the laws which regulate the ordinary phenomena of nature.

The absurdities of Egyptian superstition formed a basis for what followed among the Greeks and Romans, who had no idea of an omnipresent and omnipotent God, the creator and ruler of the universe. Their notions of divinity, like those of other pagans, were grovelling and contemptible. The gods whom they adored were imagined to have been at one period rulers or heroes on earth, and still had their habitation somewhere within the Grecian territory, or at no great distance from it. Besides their belief in this vain mythology, both Greeks and Romans put faith in divination, oracles, the magical power of amulets, and dreams. Bees, ants, and various reptiles and beasts, were imagined to have the power of giving omens of good or bad fortune. The phenomena of the atmosphere and planetary bodies were likewise a fertile source of superstitious delusions. The appearance of comets, and also eclipses, were ominous of great public disasters, it being the general belief that they were special signs made by the gods to warn mankind of approaching troubles; in all which we see a lamentable proof of the follies to which even a refined people may be exposed, if ignorant of the laws of nature.

The superstitious delusions of the Greeks and Romans may be said to have died out at the final dismemberment of the Roman empire, and the overrunning of western Europe by the Gothic nations. The introduction of Christianity also tended powerfully to root out the old superstitious usages, though a few survived to a later date. For these reasons the superstitions and

matters of credulous belief which afterwards affected the people of northern and western Europe, including the British islands, were in a great measure of Scandinavian and Gothic origin. The only superstitions of eastern growth worth mentioning, which were perpetuated in Europe generally, was that of astrology, or a belief that the stars exercised an influence over the destiny of mortals; and alchemy, or the pretended art of transmuting the baser metals into gold; both of which delusions finally vanished before the light of knowledge that spread abroad in the seventeenth and eighteenth centuries.

SCANDINAVIAN SUPERSTITIONS.

The superstitions of the European Northmen, or Scandinavians—under which term are included the early inhabitants of Denmark, Norway, Sweden, and Iceland—were of a kind remarkably accordant with the cold and stern character of the regions which they occupied. Like the ancient Greeks, the Scandinavians had seats of the gods and of the blest, which they called Asgard and Valhalla (or Valhalla), and these bore the same relation in their character to the Olympus and Elysium of the Greeks, that the countries of the north, with their stormy climes, their icy mountains, and perilous waters, bore to the perfumed and verdant plains of Hellas, and the fair blue skies overhanging the smooth Ionian Sea. Nothing could afford better proof of the utterly fanciful nature of all these mythologies, than the fact that they were thus modelled and modified in every case by the earthly habits, likings, territorial position, and ignorance of geography and astronomy, of the individual tribes among whom they respectively originated.

The deification of one or more great princes or rulers seems to have constituted the basis of the Scandinavian as well as of every other pagan mythology. Odin, the supreme deity of the Scandinavians, and the ruler of heaven and earth, appears, like the Hellenic Jupiter, to have been a distinguished chief and warrior of early times. Although it is asserted by some that a divinity of the name of Odin was worshipped from the most remote ages, there is reason to believe that the worship of this personage, in the north at least, had its real origin a few centuries before the commencement of the Christian era, when a powerful chieftain of the name was driven by the Romans from his dominions between the Euxine and Caspian, and took refuge in Scandinavia, the whole of which he subjected to his sway. Like Mahomet, this chief appears to have established a new religion, of which he himself assumed to be the earthly head, as the servant or minister of a divine being of the same name. In the course of time, however, this distinction was entirely lost, and the persons and acts of the divine and earthly Odin became inextricably blended in the mythology and traditions of the north. The great records of the religious and legendary knowledge of the

Scandinavians, are the Eddas and Sagas of Iceland, partly written in poetry and partly in prose. The oldest of the Eddas, a series of poetical fragments, was collected from oral tradition in the eleventh century, and the others are of later date. The acts of the deities and heroes of the north, the creation of the world, and prophetic revelations, form the general subject of these pieces.

The Scandinavians, like the Greeks, believed that the universe was originally a chaos, or mass of confused vapours, peopled by a race of Rimthursar, or evil spirits of gigantic bulk. A being of nobler nature sprang up among these, named Bure, from whom were descended Odin and his two brothers Vile and Ve. These younger divinities followed exactly the same course with the northern giants, that was pursued by Jupiter and his brothers with regard to the Titans, or older and gigantic deities of Greece. Odin began to war with the Rimthursar, and having at last overcome their great chief Ymer, he created the world out of that giant's body. His flesh became the mould, his bones the rocks, his hair the vegetable tribes, his blood the ocean, and his skull the heavens, at the four corners of which were placed certain dwarfs, called North, South, East, and West, whose duty it was to sustain the celestial dome. After this, the luminaries of the sky were set in their places, and the order of the seasons appointed. Natt (night) wedded one of the Aser, or celestial family of Odin, and gave birth to Dag (day). These deities travel alternately round the world in cars, drawn by single horses. Every great body, as in the Grecian mythology, was represented by a divinity. Frigga, or the earth, was the daughter of Odin, and also became his wife. The inhabitants of the earth, or mankind, were created by Odin and his brothers. Two pieces of wood, the one of ash and the other of elm, formed the materials of the first pair of mortals, who were distinguished for personal beauty and intellectual ability.

The race of deities inhabited Asgard, a place supposed by some to have been the city in Asia whence the real or mortal Odin was expatriated. The fabulous Asgard was pictured as containing numerous palaces and halls, the largest of which was the Mansion of Joy, where Allfader (Odin) sat on his throne amid his divine family. This throne was named Lidskialfa, or the Terror of Nations, and from it he could overlook the whole earth. Two ravens, Hugin (Spirit) and Muninn (Memory), sat always at his ear, and communicated to him intelligence of all things that were going on in the universe. Among the deities who dwelt in Asgard, one of the most important was Thor, or Asathor, son of Odin by Frigga, and the Mars, or warrior-god, of the Scandinavians.

Thor is described as the god of thunder, and the strongest of beings, earthly or heavenly. He is the son of Odin and Frigga, or, in other words, of the Sun and the Earth. When he moves, the earth trembles. He holds in his hand a powerful hammer, called the Crusher (*mjölner*), with which he annihilates all who oppose him, and who offend the gods. In battle Thor is always girt with a magic girdle, which has the power of inspiring him with a divine fury, and redoubling his strength. On his right hand he wears an iron gauntlet, with which he grasps and wields the formidable crusher. This latter instrument was forged by a dwarf, named Sindri, the prototype of the deformed blacksmith-deities of the Greeks, Vulcan and his Cyclops. The hammer possesses the wonderful power of never missing its aim, and when launched at any object, returns to the hand of Thor, after having destroyed his foe. Thor is sometimes called Aukistor, or Thor of the Car, from his riding on a chariot, drawn by two powerful he-goats, named Sangniotr and Tangrisner. This deity has a spouse named Sipia, famous for her beautiful hair.

After Odin, Thor was the most cherished deity of Scandinavia, and had statues and temples erected to him every where. The statues of him were usually formed of clay, and represented a tall figure, with a red-painted beard, indicative of the lightning which he

was supposed to wield. Bread and meat were supplied daily to the god by his worshippers, and at stated times libations were poured out in his honour.

Balder, the second son of Odin, was the most beautiful and amiable of the Aser or gods. Unlike the rest of his brethren, he was fond of peace, and had the power of allaying tempests, and acting as a mediator, to avert divine wrath. His decrees were irrevocable. In some points he resembled the Apollo of the Greeks, but the general qualities of that personage found a closer representative in Braga or Bragi, the god of eloquence and poetry. Niord, the god of the sea, and his son Freys, the god of rain, were also important deities of the north. Every element, or important natural phenomenon, was under the guidance, in like manner, of some celestial personage. Frigga, the Scandinavian Juno, was the bestower of fertility and plenty. Freia, or Freya, the daughter of Niord, was the Venus of Asgard and the patroness of matrimony. Freia was assisted in her duties by Siona and Sofna, the first of whom made lovers faithful, while the other reconciled them when they quarrelled. Eyra was the physician of the gods. There were various other minor divinities in the Scandinavian mythology, though not nearly so many as in the Grecian roll. The deficiency was made up among the northerns by the assignment of more multitudinous duties to the greater deities. Thus Odin, from the extent of his government, received as many as one hundred and twenty distinct names, each indicating some individual quality ascribed to him.

The great hall appointed for the reception of the spirits of the brave, when they left earth for the seat of the gods, was called Valhalla. Twelve beautiful yet terrible nymphs, named Valkyries (*choosers of the slain*), were the guides of the good spirits to the hall of Valhalla, and supplied them with mead. The occupation of drinking this northern nectar, and of eating the fat of the wild boar Serimner, which, after serving as the daily food of thousands, became whole again every night, filled up all those intervals of time in Valhalla that were not passed in fighting. None but those who had shown surpassing bravery on earth were admitted into this Scandinavian paradise, and when there, their daily amusement was to fight with one another till all or nearly all were cut in pieces. But little harm was done in this way, for the spiritual bodies soon reunited, and enabled the warriors to appear, entire in limb and limb, at the feasts that followed these extraordinary engagements. The skulls of enemies were the drinking-cups used at the entertainments of Valhalla, and the guests are described as being almost perpetually in a state of inebriation. It was only when the cock announced the arrival of morning that these terrible heroes arose from table, to issue to the field of battle through the five hundred and forty gates of Valhalla, and hack each other to pieces anew. Such was the never-ending round of employment destined for the departed heroes of Scandinavia.

The mythology of the Scandinavians survived till a much later date than any other system of heathen worship in Europe. It was not abolished till the eleventh century. St Olaf, King of Norway, and a zealous supporter of Christianity, usually receives the credit of having overturned this most barbarous form of religion. In the course of his efforts to Christianise his subjects, he ordered a statue of Thor, and the pedestal on which it stood, to be broken in pieces, and showed the people that the meat which had been laid down for the use of the god was not eaten by him, but by a host of rats and other vermin that had formed a lodgement about the foundation of the colossal image. Whatever might have been the influence of the mythology of the Scandinavians in Britain, it disappeared shortly after its overthrow on the continent of Europe, or only lingered in a kind of traditional existence amidst the remote islands of Orkney and Shetland, till finally banished by the progress of a more general intelligence. The dread names of Odin, Thor, and other deities of the north, who for centuries weighed

down the human faculties, and kept up the reign of superstition, are now only perpetuated in the appellations affixed to some of the days of the week. Thus our term *Wednesday* is derived from Odin's or Wodin's day, that being the day of the week in which the northern Jupiter or supreme ruler of the gods was most honoured and worshipped. *Thursday* is from Thor, the second in dignity among these fabulous deities: as this day was called *Dies Jovis* by the Romans, we have here a confirmation that Thor the thunderer was equivalent either to Mars, or the thundering Jove of the Grecian mythology. *Friday* takes its appellation from Freya, the daughter of Niörd, and corresponds with the *Dies Veneris*, or Venus day of the Greeks and Romans. *Saturday* is derived in the same manner from the god Saeter of the Scandinavians, and Saturn of the Greeks. *Tuesday*, or anciently *Tiesday* (a pronunciation still preserved in Scotland), is supposed to be from Tisa, the wife of Thor, and the reputed goddess of Justice. *Sunday* and *Monday* were respectively named from the Sun and Moon, both by the northern and southern nations of Europe, from a remote period of time. The circumstance of there being such a marked resemblance between the characters of the deities whose names were employed to distinguish the same days of the week both by Greeks and Scandinavians, is not a little remarkable, and has never, as far as we know, been the subject of explanation by philologists or antiquaries. The fact is only certain, that the names of the days of the week now used by every civilised people, are based upon the mythological observances of either the Grecian or Scandinavian races.

ANGLO-SAXON SUPERSTITIONS.

At a comparatively early era, the mythology and minor superstitions of the Scandinavians, as well as the follies of Druidism, disappeared in Britain as the familiar superstitions of the Anglo-Saxon race became predominant. Like the Scandinavians of the north, the Anglo-Saxons deduced their descent from Odin, whom they worshipped along with Thor, Freya, and other imaginary deities of the Gothic people. They also worshipped idols emblematic of the sun, moon, earth, and various seasons and circumstances. In particular, they sacrificed to one goddess called Eostre, in the month of April, and her name still expresses the festival of Easter in the Christian church. In token of devotional feelings towards the sun, they solemnised a festival to that luminary on the day of December in which the days began to lengthen, a log of wood being burnt on the occasion as an emblem of returning light and heat. From this ancient practice, therefore, may be traced the custom of burning the Yule log at Christmas, which is still continued in many parts of England. Among the Anglo-Saxon superstitions was included a belief in giants, dwarfs, and elves, all of a spiritual order, but partaking in some degree of human attributes and feelings. In the term *elfi* or *elves*, we have one of the earliest traces on record of those ideal fairy tribes who afterwards figured in the familiar superstitions of the British islands. The Gothic nations, of whom the Anglo-Saxons were a branch, had various orders of elves, who were understood to haunt the fields, the woods, mountains, and waters, and received denominations accordingly, as field-elfin, dun-elfin, &c. Whether this varied race of spirits originated in the east, whence so many superstitions spread into ancient Europe, is not satisfactorily known, although it is probable that they did, and were of the same genus as the *peri* of the Persians, a being not dissimilar in character to our fay or fairy. Both in the Scandinavian and Anglo-Saxon superstitions, elves formed an important order of beings, not unlike in character to the demigods, naiads, driads, and other imaginary spirits of the Greek and Roman mythologies, and like them exerted a certain influence over human affairs.

Besides a belief in these mysterious elfin tribes, the Anglo-Saxons brought with them to England the still

darker and more dangerous doctrines of witchcraft and divination, before which the reasoning powers of the people quailed, and all intellectual advancement was impeded. The general introduction of Christianity about the year 600, abolished, as a matter of course, the more gross pagan observances, but failed to extirpate the familiar and less obvious superstitions of the people. Witchcraft, wizardry, magic, divination, preparations of charms, and other mystic follies having no foundation in truth, continued to flourish, although opposed both by the more intelligent clergy and the kings. It is from the statutes, indeed, which Alfred, Canute, and other monarchs, passed for the prevention of magical practices, that we chiefly know their nature and extent. *Wiglaer*, a wizard, and *wicca*, a witch, are persons severely denounced. Penalties are enjoined if any one should destroy another by *wicecraft*. They appear to have used philtres, for it is declared a crime in any one to use witchcraft, or potions to produce another's love. Canute enjoins his people not to worship fire or floods, wells or stones, or any sort of tree; not to frame death-spells, either by lot or otherwise; and not to effect any thing by phantoms. Wizards, we also learn, pretended to the power of letting loose tempests, and controlling the visible operations of nature.

The introduction of Christianity, as has been mentioned, failed to dissipate the familiar superstitions of the English; a circumstance which can excite no surprise, as no pains were taken to enlighten the understandings of the people, or make them acquainted with the true causes of natural phenomena. We accordingly find, that from the seventh to the sixteenth century, the belief in demons, spirits, lubber fiends, and elves, of every shade and character, prevailed without intermission, and with no further challenge from the clergy than as being individually manifestations of the devil, on whom now the whole load of superstition was based. One goblin, in particular, formed the theme of innumerable legends. What was his name originally in continental Europe, whence he emigrated with the Anglo-Saxons, is of little consequence; in England he became known by the title of Father Rush, from a belief that he had on one occasion personated a monk or friar, and to serve his own malignant purposes, had in that capacity long imposed on a religious brotherhood; afterwards, this appellation went out of repute, and he was popularly known and feared by the familiar name of Robin Goodfellow, and performed many useful services in the rural districts of England. It is not a little strange that both monks and clergy sanctioned these fancies, and increased their number by the propagation of legends, which we venture to say could not now receive the approbation of a single individual, lay or clerical, in England. Of these it is only necessary to mention the absurd stories which were fabricated and circulated respecting Dunstan, Abbot of Glastonbury, and afterwards Archbishop of Canterbury, who died in the year 988. When a boy, he is stated to have studied theology so sedulously as to reduce him to the point of death, when he was suddenly restored by some divine medicine sent to him by an angel in a storm. So extraordinary a circumstance could not but demand grateful thanksgivings, and Dunstan started from his bed and ran with full speed towards the church. Satan met him in the way, surrounded with numerous black dogs, and endeavoured to defeat his pious intention. But Dunstan was not to be overcome; he instantly prayed for ability, and was enabled to cudgel the devil and his black dogs so effectually, that they left him and the angel together; the latter of whom, finding the church door fastened, took up the pious youth in his arms, and conveyed him to his devotions through the roof. Another time the devil attempted to intrude himself upon St Dunstan's studies in his laboratory, but the saint speedily punished his impertinence, by taking from the fire his tongs, which were red hot, and with them seized the nose of the fiend, who was thereupon glad to make his escape. It is lamentable to think how such vain imaginations should have so long weighed upon the

understandings of the people, and engrafted a habitual dread of the supernatural, which till this day exerts an influence over the untutored mind.

FAIRIES.

Among the various supernatural beings to whom the ignorance and credulity of mankind have given an imaginary existence, the Fairies occupy a prominent place, and are especially worthy of notice. The characters of different classes of spirits have become so mingled and confounded together in the lapse of time, that it is difficult to define individual species with correctness and precision; but there is one characteristic which appears to distinguish the fairy from every other being of a similar order. Most spirits could contract and diminish their bulk at will, but the fairy alone seems to have been regarded as essentially small in size. The majority of other spirits, also, such as dwarfs, brownies, and the like, are represented as deformed creatures, whereas the fairy has almost uniformly been described as a beautiful miniature of the human being, perfect in face and form. These points of distinction, with a dress of pure green, are the principal ones which mark the personal individuality of the fairies as a supernatural race.

The origin of the fairy superstition is ascribed by most writers to the Celtic people, but the blending of the Gothic tribes with the Celts led to the admixture of many attributes of the northern spirits with those proper to the fairies. Thus, the latter race, which appears to have been intrinsically good and benevolent, has been gifted with attributes of the very opposite kind, borrowed from the trolls and elves of the north. In Scotland, and other countries where the Celtic traditions predominated, the fairies retained, in part, the original and better features of their character, and were usually called the Good Neighbours, or the Men of Peace; but even there, their character was deteriorated by a considerable leaven of elfin or dwarfish malignancy. This evil part of their nature caused much annoyance to mankind, and, more especially, their propensity to the kidnapping of human beings. Unchristened infants were chiefly liable to this calamity, but sometimes adult men and women were also carried off. The reason for these abductions is to be found, according to the authorities on this subject, in the necessity which the fairies lay under of paying "kane," as it was called, to the master-fiend, or, in other words, of yielding up one of their number septennially into his hands by way of tribute. They greatly preferred on such occasions to make a scape-goat of some member of the human family. They also carried off young married women to be nurses to their infants; and in Ireland, at this day, when a young woman falls victim to puerperal disease, the country people firmly assert that she has been removed for this purpose.

The necessity for the latter kind of kidnapping shows the fairies to have been *family* people. They are always represented as living, like mankind, in large societies, and under a monarchical form of government. The Salique law seems to have had no countenance among them, for we more often hear of fairy queens than of fairy kings, though both are frequently spoken of. The Land of Faerie was situated somewhere under ground, and there the royal fairies held their court. In their palaces all was beauty and splendour. Their pageants and processions were far more magnificent than any that eastern sovereigns could get up, or poets devise. They rode upon milk-white steeds. Their dresses, of brilliant green, were rich beyond conception; and when they mingled in the dance, or moved in procession among the shady groves, or over the verdant lawns of earth, they were entertained with delicious music, such as mortal lips or hands never could emit or produce. At the same time, most of the legendary tales on the subject represent these splendours as shadowy and unsubstantial. When the eye of a seer, or any one gifted with supernatural powers, was turned upon the fairy pageantries or banquets, the illusion vanished.

Their seeming treasures of gold and silver became slate-stones, their stately halls became damp caverns, and they themselves, from being miniature models of human beauty, became personifications of fantastic ugliness. In short, the Fairy Eden was a dream—a thing of show without substance.

This is the general account given of the fairy state, but few of the legends on the subject agree on all points. From a very early period, however, every fairy annalist concurred in giving to the king and queen of the fairies the names of Oberon and Titania. Oberon is the Elberich or Rich Elf of the Germans, and was endowed with his modern name, as well as with new attributes, by the old French romancers, who represented him as a tiny creature of surpassing loveliness, with a crown of jewels on his head, and a horn in his hand that set all who heard it to the dancing.

It was the belief that unchristened children were peculiarly liable to be carried off by the fairies, who sometimes left little changelings, of their own blood, in place of the infants of mortal kind. Ben Jonson, in his *Sad Shepherd*, makes the tending and nurture of human changelings to be one of the favourite elfin employments.

There, in the stocks of trees, white fays do dwell,
And span-long elves, that dance about a pool,
With each a little changeling in their arms."

Various charms were used in Scotland for the restoration of stolen children. The most efficacious was believed to be the *roasting* of the supposititious child upon live embers, when it was understood that the false infant would disappear, and the true one be left in its place. It is to be hoped, that this cruel and monstrous practice was seldom followed. The possession of what are called *toadstones* was also held to be an efficient preservative against the abduction of children by the fairies. In Waldron's Account of the Isle of Man, we find various stories of children kidnapped by the fairies. In one case, where a woman had given birth to a child, her attendants were enticed from the house by a cry of "Fire!" and while they were out, the child was taken from the helpless mother by an invisible hand; but the sudden re-entry of some of the gossips compelled the fairies to drop the child, and it was found sprawling on the threshold. The fairies, who seemed to have taken a particular liking to this woman's offspring, tried to carry off her second child in the same way, but failed again. On a third trial, they succeeded, and left behind them a changeling, a withered and deformed creature, which neither spoke nor walked during an existence of nine years, and ate nothing but a few herbs. It is to be feared that this changeling superstition must have been the cause of much deplorable cruelty. That very member of a family, who from natural misfortunes and defects required the kindest tending, would but too often be neglected and wretchedly misused, on the plea of its being an alien. We may smile at many of the credulous fancies respecting the fairies, but there are in this order of superstitions, as in almost all others, some points which strongly exhibit to us the baleful effects inevitably attendant upon ignorance of every kind.

Numberless stories of a ridiculous kind have been told relative to the intercourse of the fairies with mankind. Some of the poor creatures arraigned in Scotland in past times for witchcraft, admitted having had correspondence with the fairies. There can be little doubt that these wretched beings, whom the *torture* forced into the confession of *some* kind or other of supernatural traffic, were induced to admit an association with fairies, in the hope that this would be looked upon as less sinful than a league with the enemy of mankind. The trials of Bessie Dunlop and Alison Pearson, in the years 1576 and 1593, illustrate this statement. Bessie Dunlop avowed that her familiar was one Thome Reid, the ghost of a soldier slain at Pinkie in 1547, and who after his death seems to have become an inmate of Elf-land. She related that this Thome Reid, who appeared fre-

quently to her in the likeness of an elderly man, grey-coated and grey-bearded, wished her to go with him to the fairy country, and gave her herbs to cure various diseases. He even once brought to her the queen of the fairies, who, to the confusion of poetry, was a fat woman, fond of ale, and, in short, most unlike the Titania of romance. Alison Pearson also admitted her familiarity with the fairies, from whom she frequently received herbs for the cure of disease. It is remarkable that Patrick Adamson, an able scholar and divine, who was created Archbishop of St Andrews by James VI., actually took the medicines prescribed by this poor woman, in the hope that they would transfer an illness with which he was seized to the body of one of his horses. This feat, it was believed, was accomplished by the prescription. The unfortunate women who confessed these things, were deceived in the expectation which led to the act. They could not so save themselves. They were both convicted, and perished at the stake.

It may not be improper in this place to allude to the fancies of the poets on the subject of the fairies. Shakespeare stands pre-eminent in this department. His *Midsummer Night's Dream* is a poem of exquisite beauty, and one corresponding in every respect with the delicately fanciful nature of the subject. In *Romeo and Juliet*, he has also described an important fairy, Queen Mab, who has almost dethroned Titania of late years. Mr Tennant's *Anster Fair* has been of great avail to the fame of Mab. Whoever chooses to consult Drayton and the poets mentioned, will have the pleasure of observing and enjoying the exercise of poetical fancy of the highest order on the subject of fairies.

The superstitions now described are not yet extinct in the British Islands. In Ireland, the Scottish Highlands, and Wales, in particular, the fairies are yet objects of general belief. Education has not yet shed its enlightening influence there, and by education alone can the darkness of superstition be dispelled. This is almost a truism, for superstition and ignorance are nothing else than equivalent terms. The spirit is abroad, however, which will extinguish this remnant of barbarism, and it is consoling to think so, for the ills which have flowed from this source are numberless.

WITCHCRAFT.

A belief that certain individuals possessed magical powers, and could exercise a supernatural influence over their fellow-creatures, existed in ancient Rome, and those who practised, or rather *pretended* to exercise, such arts, were punishable by the civil magistrate. It is to be observed, that neither among the Romans nor the Pagan nations of northern Europe, was witchcraft deemed an offence against *religion*; in some instances, indeed, the witch was supposed to derive her powers from spirits friendly to mankind, and her profession, though feared, was held in honour by her infatuated dupes. Upon the introduction of Christianity, witchcraft assumed a new form, though retaining all its old attributes. Instead of ascribing the supernatural powers of the practitioner to the gods, to Odin, to spirits of good or evil qualities, or to supposed mysteries in nature, the people imputed them to the great fallen spirit mentioned in Scripture. This potent being, from a wicked desire to destroy all that was good and hopeful in man's destiny, was believed to enter into a compact with the aspirant witch, in which, for an irrevocable assignment of her soul at death, he was to grant all her wishes, and assist in all her malevolent projects. These new features in witchcraft, as we shall speedily perceive, thoroughly changed and prodigiously extended the superstition throughout Europe. From being rather a sportive kind of jugglery, or trick in practical magic, and at most only a civil offence, it was recognised as a crime of the deepest dye, meriting the most severe chastisement which the ecclesiastical and civil power could inflict.

We must here notice, however, that the demon or master-fend of the witchcraft legends was a very differ-

ent being from that great fallen spirit, held, in a graver view of things, so deeply to influence the best interests of humanity. As this superstition gained force in the Christian world, which it did by slow and successive steps through the whole of the middle ages, or from the fifth century till about the fifteenth, the devil—for it is impossible to avoid the mention of this emphatic name, disagreeable as it is commonly said to be to ears polite—gradually lost many of the former features of his character; or, rather, a different being was substituted for him, combining the characteristics of the Scandinavian Lokke with those of a Satyr of the heathen mythology—a personage equally wicked and malicious as the sterner spirit of evil, but rendered ludicrous by a propensity for petty trickery, and by such personal endowments as a pair of horns, a cow's tail, and cloven feet. There can be no doubt that the demon of the middle ages borrowed these attributes from his human representatives in the old mysteries and plays, where a laudable endeavour was made to make the evil one as ugly as possible. We are told, it is true, that he could at will assume any specious disguise that suited him, but the eye of the initiated observer could readily detect the "cloven foot"—or, in other words, penetrate his true character. Such as he was, he played an important part in the annals of modern witchcraft, which was supposed to rest entirely on the direct and personal agency of himself and the imps commissioned by him. Nor was this supposition confined to the illiterate, or to persons of peculiarly credulous temperament. Authors, distinguished for sense and talent, record with great seriousness, that the devil once delivered a course of lectures on magic at Salamanca, habited in a professor's gown and wig; and that at another time he took up house in Milan, lived there in great style, and assumed, rather imprudently one would say, the suspicious yet appropriate title of the "Duke of Mammon." Even Luther entertained similar notions about the fiend, and, in fact, thought so meanly of him as to believe that he could come by night and steal nuts, and that he cracked them against the bedposts, for the solacement of his monkey-like appetite.

The powers ascribed to this debased demon were exceedingly great. The general belief was, that through his agency storms at sea and land could at all seasons be raised; that crops could be blighted and cattle injured; that bodily illnesses could be inflicted on any person who was the object of secret malice; that the dead could be raised to life; that witches could ride through the air on broomsticks, and transform themselves into the shapes of cats, hares, or other animals, at pleasure. An old writer, speaking of the powers of witches, says—"1. Some work their bewitchings only by way of invocation or imprecation. They wish it, or will it; and so it falls out. 2. Some, by way of emissary, sending out their imps, or familiars, to cross the way, jostle, affront, flash in the face, barke, howle, bite, scratch, or otherwise infest. 3. Some by inspecting, or looking on, or to glare, or peep at with an envious and evil eye. 4. Some by a hollow muttering or mumbling. 5. Some by breathing and blowing on. 6. Some by cursing and banning. 7. Some by blessing and praising. 8. Some revengefully, by occasion of ill turns. 9. Some ingratelully, and by occasion of good turns. 10. Some by leaving something of theirs in your house. 11. Some by getting something of yours into their house. 12. Some have a more speciall way of working by severall elements—earth, water, ayre, or fire. But who can tell all the manner of wayes of a witch's working; that works not only darkly and closely, but variously and versatilly, as God will permit, the devil can suggest, or the malicious hag devise to put in practice?"

In the present age of comparative intelligence, it is difficult to understand how human beings could be so deplorably ignorant as to entertain such a gross superstition. We must, however, recollect that the belief was greatly fostered by religious impressions, and that it was long considered a mark of impiety to doubt the existence of witches. Various other circumstances

helped to cherish and magnify the error. The true causes of the majority of natural phenomena were unknown. The nature of the atmosphere, and of certain meteoric appearances—of the laws which regulate storms at sea, and tides—of human maladies and their remedies—were enveloped in obscurity. Natural causes being unknown, and the very doctrine of them unacknowledged, the weak and easily terrified mind flew to the conclusion that all evil proceeded from a power malignant to man, and that by certain impious dealings it was possible for man himself to direct that power against his neighbour.

The superstition seems to have approached its height about the end of the fifteenth century. In his bull of 1484, Pope Innocent charged inquisitors and others to discover and destroy all such as were guilty of witchcraft. This commission was put into the hands of a wretch called Sprenger, with directions that it should be put in force to its fullest extent. Immediately there followed a regular form of process and trial for suspected witches, entitled *Malleus Maleficarum*, or a Hammer for Witches, upon which all judges were called scrupulously to act. The edict of 1484 was subsequently enforced by a bull of Alexander VI. in 1494, of Leo X. in 1521, and of Adrian VI. in 1522, each adding strength to its predecessor, and the whole serving to increase the agitation of the public mind upon the subject. The results were dreadful. A panic fear of witchcraft took possession of society. Every one was at the mercy of his neighbour. If any one felt an unaccountable illness, or a peculiar pain in any part of his body, or suffered any misfortune in his family or affairs, or if a storm arose and committed any damage by sea or land, or if any cattle died suddenly, or, in short, if any event, circumstance, or thing occurred out of the ordinary routine of daily experience, the cause of it was witchcraft. To be accused was to be doomed, for it rarely happened that proof was wanting, or that condemnation was not followed by execution. Armed with the *Malleus Maleficarum*, the judge had no difficulty in finding reasons for sending the most innocent to the stake. If the accused did not at once confess, they were ordered to be shaved and closely examined for the discovery of devil's marks; it being a tenet in the delusion that the devil, on inaugurating any witch, impressed certain marks on her person; and if any strange mark was discovered, there remained no longer any doubt of the party's guilt. Failing this kind of evidence, torture was applied, and this seldom failed to extort the desired confession from the unhappy victim. A large proportion of the accused witches, in order to avoid these preliminary horrors, confessed the crime in any terms which were dictated to them, and were forthwith led to execution. Other witches, as has been said, seemed to confess voluntarily, being probably either insane persons, or feeble-minded beings, whose reason had been distorted by brooding over the popular witchcraft code. A few extracts from the work of Dr Hutchinson will show the extent of these proceedings:—

"A.D. 1485.—Cumanas, an inquisitor, burnt forty-one poor women for witches, in the county of Burlia, in one year. He caused them to be shaven first, that they may be searched for marks. He continued the prosecutions in the year following, and many fled out of the country.

About this time, Alciat, a famous lawyer, in his *Parerga*, says, 'One inquisitor burnt a hundred in Piedmont, and proceeded daily to burn more, till the people rose against the inquisitor, and chased him out of the country.'

A.D. 1488.—A violent tempest of thunder and lightning in Constance destroyed the corn for four leagues round. The people accused one Anne Mindelin, and one Agnes, for being the cause of it. They confessed, and were burnt.

About this time, H. Institor says, one of the inquisitors came to a certain town, that was almost desolate with plague and famine. The report went, that a cer-

tain woman, buried not long before, was eating up her winding-sheet, and that the plague would not cease till she had made an end of it. This matter being taken into consideration, Scultetus, with the chief magistrate of the city, opened the grave, and found that she had indeed swallowed and devoured one-half of her winding-sheet. Scultetus, moved with horror at the thing, drew out his sword, and cut off her head, and threw it into a ditch, and immediately the plague ceased! and, the inquisition sitting upon the case, it was found that she had long been a reputed witch.

A.D. 1524.—About this time a thousand were burned in one year, in the diocese of Como, and a hundred per annum for several years together."

From other authorities it is learned that the devastation was as great in Spain, France, and northern Germany, as it was in the Italian states. About the year 1515, five hundred witches were burned in Geneva in three months, and in France many thousands. An able writer in the *Foreign Quarterly Review*,* sums up the following particulars respecting the executions for witchcraft in some of the German states:—

"In Germany, to which indeed the bull of Innocent bore particular reference, this plague raged to a degree almost inconceivable. Bainberg, Paderborn, Wurtzburg, and Treves, were its chief seats, though for a century and a half after the introduction of the trials under the commission, no quarter of that great empire was free from its baneful influence. A catalogue of the executions at Wurtzburg for the period from 1627 to February 1629, about two years and two months, is printed by Hauber in the conclusion of his third volume of the *Acta et Scripta Magica*. It is regularly divided into twenty-nine burnings, and contains the names of 157 persons, Hauber stating at the same time that the catalogue is not complete. It is impossible to peruse this list without shuddering with horror. The greater part of this catalogue consists of old women or foreign travellers, seized, as it would appear, as foreigners were at Paris during the days of Marat and Robespierre: it contains children of twelve, eleven, ten, and nine years of age; fourteen vicars of the cathedral; two boys of noble families, the two little sons of the senator Stolzenburg; a stranger boy; a blind girl; Gobel Babelin, the handsomest girl in Wurtzburg, &c. And yet, frightful as this list of 157 persons executed in two years appears, the number is not (taking the population of Wurtzburg into view) so great as the Lindheim process from 1660 to 1664; for in that small district, consisting at the very utmost of 600 inhabitants, thirty persons were condemned and put to death, making a twentieth part of the whole population consumed in four years.

How dreadful are the results to which these data lead! If we take 157 as a fair average of the executions at Wurtzburg (and the catalogue itself states that the list was by no means complete), the amount of executions there in the course of the century preceeding 1628, would be 15,700. We know that from 1610 to 1660 was the great epoch of the witch trials, and that so late as 1749, Maria Renata was executed at Wurtzburg for witchcraft; and though in the interval between 1660 and that date, it is to be hoped that the number of these horrors had diminished, there can be little doubt that several thousands fall to be added to the amount already stated. If Bainberg, Paderborn, Treves, and the other Catholic bishoprics, whose zeal was not less ardent, furnished an equal contingent, and if the Protestants, as we know, actually vied with them in the extent to which these cruelties were carried, the number of victims from the date of Innocent's bull to the final extinction of these prosecutions, must considerably exceed 100,000 in Germany."

WITCHCRAFT IN SCOTLAND.

The mania respecting witchcraft, which sprang up into vigour throughout southern Europe in consequence

of the edicts of Innocent and Leo, spread in time to Scotland, and acquired strong possession of the public mind during the reign of Queen Mary. At that period, an act was passed by the Scottish Parliament for the suppression and punishment of witchcraft; but this only served, as the papal bulls had done, to confirm the people in their maniacal credulity, and to countenance and propagate the general delusion. In terms of these ill-judged statutes, great numbers of persons, male as well as female, were charged with having intercourse with the devil, convicted, and burned on the Castlehill of Edinburgh and elsewhere. This continued during the earlier part of the reign of James VI., whose mind, unfortunately for the more aged of the female part of his subjects, was deeply impressed with the flagrant nature of the crime of witchcraft. In 1590, James, it is well known, made a voyage to Denmark to see, marry, and conduct home in person, his appointed bride, the Princess Anne. Soon after his arrival, a tremendous witch conspiracy against the happy conclusion of his homeward voyage was discovered, in which the principal agents appeared to be persons considerably above the vulgar. One was Mrs Agnes Sampson, commonly called the *Wise Wife of Keith* (Keith being a village in East-Lothian), who is described as "grave, matron-like, and settled in her answers." On this occasion, the king was induced by his peculiar tastes to engage personally in the business of judicial investigation. He had all the accused persons brought before himself for examination, and even superintended the tortures applied to them to induce confession. The statements made by these poor wretches form a singular tissue of the ludicrous and horrible in intimate union.

"The said Agnis Sampson was after brought again before the king's majestie and his council, and being examined of the meetings and detestable dealings of those witches, she confessed, that upon the night of All-Hallow-even she was accompanied, as well with the persons aforesaid, as also with a great many other witches, to the number of two hundred, and that all they together went to sea, each one in a riddle, or sieve, and went in the same very substantially, with flaggons of wine, making merrie and drinking by the way in the same riddles, or sieves, to the Kirk of North-Berwick, in Lothian, and that after they had landed, took hands on the land, and danced this reil, or short daunce, singing all with one voice,

"Cummer, goe ye before, cummer, goe ye;
Gif ye will not goe before, cummer, let me."

At which she confessed that Geillis Duncan did goe before them, playing this reil or daunce upon a small trump, called a Jew's harp, until they entered into the Kirk of North-Berwick. These made the king in a wonderful admiration, and he sent for the said Geillis Duncan, who upon the like trump did play the said daunce before the king's majestie, who, in respect of the strangeness of these matters, took great delight to be present at their examinations."

In the sequel of Agnes Sampson's confession we find some special reasons for the king's passionate liking for these exhibitions, in addition to the mere love of the marvellous. The witches pandered to his vanity on all occasions, probably in the vain hope of mitigating their own doom. Agnes Sampson declared that one great object with Satan and his agents was to destroy the king; that they had held the great North Berwick convention for no other end; and that they had endeavoured to effect their aim on many occasions, and particularly by raising a storm at sea when James came across from Denmark. "The witches demanded of the divell why he did beare such hatred to the king? who answered, by reason the king is the greatest enemy hee hath in the world." Such an eulogy, from such a quarter, could not but pamper the conceit of "the Scottish Solomon."

The following further points in the deposition of Agnes Sampson are worthy of notice. *Item*, She went with the witch of Carrieburn, and other witches, to the

Kirk of Newton, and taking up dead folks and jointing them [cutting off fingers, &c.], made enchanted powders for witchcraft. *Item*, She went with other witches in a boat, the devil going before them like a rock of hay. *Item*, The devil, in the shape of a dog, gave her responses concerning her laird's recovery, and endeavoured to put awa ane of the ladies' daughters. *Item*, she raised a universal great storm in the sea when the queen was coming to Scotland, and wrote a letter to that effect to a witch in Leith. *Item*, She used this prayer in the healing of sickness:—

All kinds of ill that ever may be," &c.

The repetition of these and such like verses by the confessing witches, has been matter of frequent surprise. But it must be remembered that a code of witchcraft, extensively known and accredited, existed at that day, regular forms and rules for its exercise having been laid down in the course of time. It must be recollected, also, that these poor creatures, though guiltless of all supernatural intercourse, had really pretended to the gift of healing by charms and incantations in many cases, and had to invent or learn formulas for the purpose. Besides, we find these doggerel scraps chiefly in the revelations of Agnes Sampson. She, it is stated, could write, and of course could read also; and hence she is to be regarded as a person who had had superior opportunities for acquiring a knowledge of the witchcraft code, as well as superior capabilities for filling up deficiencies on the spur of the moment. In her confession she implicated one Doctor Fian, otherwise called John Cunningham, master of the school at Saltpan, in Lothian, a man whose story may be noticed at some length, as one of the most curious and instructive in the whole annals of Scottish witchcraft.

Mrs Sampson deposed that Dr Fian was always a prominent person at the witch-meetings, and Geillis Duncan, the marvellous trump-player, confirmed this assertion. Whether made through heedlessness or malice, these averments decided Fian's fate. He was seized, and after being "used with the accustomed paine provided for those offences inflicted upon the rest, first, by *throwing of his head with a rope*, whereat he would confess nothing;" and secondly, being urged "by fair meanes to confesse his follies," which had as little effect; "lastly, hee was put to the most severe and cruell paine in the world, called the booties, when, after he had received three strokes, being inquired if he would confesse his actes and wicked life, his tongue would not serve him to speake; in respect whereof, the rest of the witches willed to search his tongue, under which was founde two pinnes thrust up into the heade, whereupon the witches did say, now is the charme stinted, and showed that those charmed pins were the cause he could not confesse any thing; then was he immediately released of the booties, brought before the king, and his confession was taken." Appalled by the cruel tortures he had undergone, Fian seems now only to have thought how he could best get up a story that should bring him to a speedy death. He admitted himself to be the devil's "register," or clerk, who took the oaths from all witches at their initiation, and avowed his having bewitched various persons. In proof of the latter statement he instanced the case of a gentleman near Saltpan, whom he had so practised upon, he said, that the victim fell into fits at intervals. This person, who seems to have been either a lunatic or afflicted with St Vitus's dance, was sent for, and "being in his majestie's chamber, suddenly hee gave a great scritch, and fell into madnesse, sometimes bending himself, and sometimes capring so directly up, that his heade did touch the seeling of the chamber, to the great admiration of his majestie." On these and other accounts Dr Fian was sent to prison, but he contrived soon after to escape from it. "By means of a hot and harde pursuite," he was retaken, and brought before the king, to be examined anew. But the unfortunate man had had time to think, and like Cranmer under somewhat similar circumstances, resolved to retract the admis-

sions which the weakness of the body had drawn from him, and to suffer any thing rather than renew them. He boldly told this to the king; and James, whom these records make us regard with equal contempt and indignation, ordered the unfortunate man to be subjected to the following most horrible tortures. "His nailes upon all his fingers were riven and pulled off with an instrument called in Scottish a *turkas*, which in England are called a *payre* of pincers, and under everie naile there was thrust in two needles over, even up to the heades; at all which tormentes, notwithstanding, the doctor never shrunk a whit, neither would he then confesse it the sooner for all the tortures inflicted on him. Then was hee, with all convenient speed, by commandement, convaied again to the torment of the bootes, wherein he continued a long time, and did abide so many blowes in them, that his legges were crusht and beaten together as small as might bee, whereby they were make unserviceable for ever." Notwithstanding all this, such was the strength of mind of the victim, or, as King James termed it, "so deeply had the devil entered into his heart," that he still denied all, and resolutely declared that "all he had done and said before was only done and said for fear of the paynes which he had endured." As, according to this fashion of justice, to confess or not to confess was quite the same thing, the poor schoolmaster of Salt-pans was soon afterwards strangled, and then burned on the Castlehill of Edinburgh (January 1591).

Much about the same time that Agnes Sampson made her confessions, some cases occurred, showing that witchcraft was an art not confined to the vulgar. A woman of high rank and family, Catherine Ross, Lady Fowlis, was indicted at the instance of the king's advocate for the practice of witchcraft. On inquiry it was clearly proved that this lady had endeavoured, by the aid of witchcraft and poisons, to take away the lives of three or more persons who stood between her and an object she had at heart. She was desirous to make young Lady Fowlis possessor of the property of Fowlis, and to marry her to the Laird of Balnagown. Before this could be effected, Lady Fowlis had to cut off her sons-in-law, Robert and Hector Munro, and the young wife of Balnagown, besides several others. Having consulted with witches, Lady Fowlis began her work by getting pictures of the intended victims made in clay, which she hung up, and shot at with arrows shod with flints of a particular kind, called elf-arrow heads. No effect being thus produced, this really abandoned woman took to poisoning ale and dishes, none of which cut off the proper persons, though others who accidentally tasted them lost their lives. By the confession of some of the assistant hags, the purposes of Lady Fowlis were discovered, and she was brought to trial; but a local or provincial jury of dependants acquitted her. One of her purposed victims, Hector Munro, was then tried in turn for conspiring with witches against the life of his brother George. It was proved that a curious ceremony had been practised to effect this end. Hector, being sick, was carried abroad in blankets, and laid in an open grave, on which his foster-mother ran the breadth of nine riggs, and, returning, was asked by the chief attendant witch, "which she chose should live, Hector or George?" She answered, "Hector." George Munro did die soon afterwards, and Hector recovered. The latter was also acquitted, by a provincial jury, on his trial.

These disgraceful proceedings were not without their parallel in other families of note of the day. Euphemia Macalzean, daughter of an eminent judge, Lord Clifton-hall, was burned at the stake in 1591, having been convicted, if not of witchcraft, at least of a long career of intercourse with pretenders to witchcraft, whom she employed to remove obnoxious persons out of her way—tasks which they accomplished by the very simple means of poisoning, where they did accomplish them at all. The jury found this violent and abandoned woman, for such she certainly was, guilty of participation in the murder of her own god-father, of her husband's nephew,

and another individual. They also found her guilty of having been at the Wise Woman of Keith's great witch-convention of North Berwick; but every witch of the day was compelled to admit having been there, out of compliment to the king, to whom it was a source of agreeable terror to think himself of so much importance as to call for a solemn convocation of the powers of evil to overthrow him. Euphemia Macalzean was "burnt in assis, *quick*, to the death." This was a doom not assigned to the less guilty. Alluding to cases of this latter class, a writer (already quoted) in the Foreign Quarterly Review remarks, "In the trials of Bessie Roy, of James Reid, of Patrick Currie, of Isobel Grierson, and of Grizel Gardiner, the charges are principally of taking off and laying on diseases either on men or cattle; meetings with the devil in various shapes and places; raising and dismembering dead bodies for the purpose of enchantments; destroying crops; scaring honest persons in the shape of cats; taking away women's milk; committing housebreaking and theft by means of enchantments, and so on. South-running water, salt, rowan-tree, enchanted flints (probably elf-arrow heads), and doggrel verses, generally a translation of the Creed or Lord's Prayer, were the means employed for effecting a cure." Diseases, again, were laid on by forming pictures of clay or wax; by placing a dead hand, or some mutilated member, in the house of the intended victim; or by throwing enchanted articles at his door. A good purpose did not save the witch; intercourse with spirits, in any shape, being the crime.

Of course, in the revelations of the various witches, inconsistencies were abundant, and even plain and evident impossibilities were frequently among the things averred. The sapient James, however, in place of being led by these things to doubt the whole, was only strengthened in his opinions, it being a maxim of his, that the witches were "all extreme lyars." Other persons came to different conclusions from the same premises, and before the close of James's reign, many men of sense began to weary of the torturings and incriminations that took place almost *every day*, in town or country, and had done so for a period of thirty years (betwixt 1590 and 1620). Advocates now came forward to defend the accused, and in their pleadings ventured even to arraign some of the received axioms of "Daemonologie" laid down by the king himself, in a book bearing that name. The removal of James to England moderated, but did not altogether stop, the witch prosecutions. After his death they slackened more considerably. Only eight witchcraft cases are on the Record as having occurred between 1625 and 1640 in Scotland, and in one of these cases, remarkable to tell, the accused escaped. The mania, as it appears, was beginning to wear itself out.

As the spirit of puritanism gained strength, however, which it gradually did during the latter part of the reign of Charles I., the partially cleared horizon became again overcast, and again was this owing to ill-judged edicts, which, by indicating the belief of the great and the educated in witchcraft, had the natural effect of reviving the frenzy among the flexible populace. The General Assembly was the body in fault on this occasion, and from this time forward the clergy were the great witch-hunters in Scotland. The Assembly passed condemnatory acts in 1640, 43, 44, 45, and 49, and with every successive act the cases and convictions increased, with even a deeper degree of attendant horrors than at any previous time. "The old impossible and abominable fancies," says the review formerly quoted, "of the *Malleus* were revived. About thirty trials appear on the Record between 1649 and the Restoration, only one of which appears to have terminated in an acquittal; while at a single circuit, held at Glasgow, Stirling, and Ayr, in 1659, seventeen persons were convicted and burnt for this crime." But it must be remembered that the phrase "on the Record" alludes only to justiciary trials, which formed but a small proportion of the cases really tried. The justiciary lists take no note of the commissions perpetually

given by the privy-council to resident gentlemen and clergymen to try and burn witches in their respective districts. These commissions executed people over the whole country in multitudes. Wodrow, Lamont, Mercer, and Whitelocke, prove this but too satisfactorily.

The clergy continued, after the Restoration, to pursue these imaginary criminals with a zeal altogether deplorable. The Justiciary Court condemned twenty persons in the first year of Charles II's reign (1661), and in one day of the same year the council issued fourteen new provincial commissions, the aggregate doings of which one shudders to guess at. To compute their condemnations would be impossible, for victim after victim perished at the stake, unnamed and unheard of. Morayshire became at this particular period the scene of a violent fit of the great moral frenzy, and some of the most remarkable examinations signalling the whole course of Scottish witchcraft took place in that county. The details, though occasionally ludicrous from their absurdity, are too horrible for narration in the present pages.

The popular frenzy seems to have exhausted itself by its own virulence in 1661-62, for an interval of six years subsequently elapsed without a single justiciary trial for the crime of witchcraft, and one fellow was actually whipped for charging some person with it. After this period, the dying embers of the delusion only burst out on occasions, here and there, into a momentary flame. In 1678, several women were condemned, "on their own confession," says the Register; but we suspect this only means, in reality, that one malicious being made voluntary admissions involving others, as must often have been the case, we fear, in these proceedings. Scattered cases took place near the beginning of the eighteenth century, such as those at Paisley in 1697, at Pittenweem in 1704, and at Spott about the same time. It is curious, that, as something like direct evidence became necessary for condemnation, that evidence presented itself, and in the shape of possessed or enchanted young persons, who were brought into court to play off their tricks. The most striking case of this nature was that of Christian Shaw, a girl about eleven years old, and the daughter of Mr Shaw of Bargarran, in Renfrewshire. This wretched girl, who seems to have been an accomplished hypocrite, young as she was, quarrelled with a maid-servant, and, to be revenged, fell into convulsions, saw spirits, and, in short, feigned herself bewitched. To sustain her story, she accused one person after another, till not less than twenty were implicated, some of them children of the ages of twelve and fourteen! They were tried on the evidence of the girl, and five human beings perished through her malicious impostures. It is remarkable that this very girl afterwards founded the thread manufacture in Renfrewshire. From a friend who had been in Holland, she learnt some secrets in spinning, and, putting them skilfully in practice, she led the way to the extensive operations carried on in that department of late years. She became the wife of the minister of Kilmaurs, and, it is to be hoped, had leisure and grace to repent of the wicked misapplication, in her youth, of those talents which she undoubtedly possessed.

The last justiciary trial for witchcraft in Scotland was in the case of Elspeth Rule, who was convicted in 1708, and—banished. The last regular execution for the crime is said to have taken place at Dornoch in 1722, when an old woman was condemned by David Ross, sheriff of Caithness. But we fear the provincial records of the north, if inquired into, would show later deaths on this score. However, here may be held to end the tragical part of the annals of Scottish witchcraft. The number of its victims, for reasons previously stated, it would be difficult accurately to compute, but the black scroll would include, according to those who have most attentively inquired into the subject, upwards of FOUR THOUSAND persons! And by what a fate they perished! Cruelly tortured while living, and dismissed from life by a living death amid the flames! And for

what? For an impossible crime! And who were the victims, and who the executioners? The victims, in by far the majority of cases, were the aged, the weak, the deformed, the lame, and the blind; those to whom nature had been ungentle in her outward gifts, or whom years and infirmities had doomed to poverty and wretchedness; exactly that class of miserable beings, in short, for whom more enlightened times provide houses of refuge, and endow charitable institutions, aiming, in the spirit of true benevolence, to supply to them that attention and support which nature or circumstances have denied them the power of procuring for themselves. Often, too, was the victim a person distinguished by particular gifts and endowments; gifts bestowed by the Creator in kindness, but rendered fatal to the possessor by man. These were the victims of witchcraft. The executioners were the wisest and greatest of their time. Men distinguished above their fellows for knowledge and intelligence, ministers of religion and of the laws, kings, princes, and nobles—these, and such as these, judged of the crime, pronounced the doom, and sent the poor victims of delusion to the torture, the stake, and the scaffold.

WITCHCRAFT IN ENGLAND.

Witchcraft was first denounced in England, by formal and explicit statutes, in the year 1541, in the reign of Henry VIII. Previously to that time, many witch-trials had taken place, and severe punishments had even been inflicted on the parties concerned; but this was occasioned by the direction of the arts of sorcery, in these particular instances, against the lives and well-being of others, and not from the legal criminality of such arts themselves. Shakespeare has made some early cases of this nature familiar to us, and in particular that of the Duchess of Gloucester, who, for conspiring with witches against the life of the reigning sovereign, Henry VI., was compelled to do public penance, and imprisoned for life. But, as has been said, the mode of prosecuting the guilty purpose was here altogether a subsidiary matter. If a person waved his hat three times in the air, and three times cried "Buzz!" under the impression that by that formula the life of another might be taken away, the old law and law-makers (as, for example, Selden, who states this very case) considered the formulist worthy of death as a murderer in intent; and upon this principle the trafficking with witches was punished in early times.

Witchcraft, however, by and bye assumed greater statutory importance, in England as elsewhere. Henry VIII.'s two acts were levelled against conjuration, witchcraft, false prophecies, and pulling down of crosses. Here the charge was still something beyond mere sorcery, and it was left for Elizabeth, in 1562, to direct a statute exclusively against that imaginary crime. At the same time, that princess extenuated her conduct in part, by limiting the penalty of the crime, when stripped of its customary accessories, to the pillory. The first transgression, at least, received no heavier punishment. The cases of Elizabeth's reign were chiefly cases of pretended possession, sometimes, however, involving capital charges against those said to have caused the possession. In one famous case, of which the main features were as ludicrous as the issue was deplorable, three poor persons, an old man named Samuel, with his wife and daughter, were tried at Huntingdon, for having bewitched the children of a Mr Throgmorton. Joan Throgmorton, a girl of fifteen, and the eldest of the children, was the main witness for the prosecution. She related many scenes, in which the actors were herself and a number of spirits sent by Dame Samuel to torment her, and to throw her into fits. These spirits, she said, were on familiar terms with her, and were named Pluck, Hardname, Catch, Blue, and three Smacks, who were *cousins*. Among other things, she said that one of the Smacks professed himself an admirer of hers, and beat the rest for her sake, as in the following instance related by her. One day Smack appeared before her. "Whence come you, Mr Smack?"

she said to him. "From fighting Pluck and the rest, with cowl-staves, in Dame Samuel's back-yard," replied Smack; and soon thereafter, accordingly, Pluck and Blue walked in, the one with his head broken, and the other limping. "How do you manage to beat them?" said the young lady to the victorious Smack; "you are little, and they are big." "Oh," says Smack, "I can take up any two of them, and my cousins beat the rest." Of such stuff were these charges made. It would appear that they were either the offspring of insanity on the part of the youthful Throgmortons, or that, having begun the farce in sport or spite, the accusers found at length that they could not retreat without a disgraceful confession of imposture. In part, the conduct of the poor Samuels was affecting, and even high-minded. After lengthened worrying, the accusers got Dame Samuel indirectly to confess her guilt, by making her repeat a prescribed charm, which had the effect of at once bringing the children out of their fits. But the old man and the daughter steadily maintained their innocence. The unfortunate family were condemned on the 4th April 1593, and soon after executed.

When James I. ascended the English throne, he unfortunately conceived it to be his duty immediately to illuminate the southern on the subject of witchcraft. An act of the first year of his reign defines the crime with a degree of minuteness worthy of the adept from whose pen it undoubtedly proceeded. "Any one that shall use, practise, or exercise any invocation of any evil or wicked spirit, or consult or covenant with, entertain or employ, feed or reward, any evil or wicked spirit, to or for ANY purpose; or take up any dead man, &c. &c. &c.; such offenders, duly and lawfully convicted and attainted, shall suffer death." We have here witchcraft first distinctly made, of itself, a capital crime. Many years had not passed away after the passing of this statute, ere the delusion, which had heretofore committed but occasional and local mischief, became an epidemical frenzy, devastating every corner of England. Leaving out of sight single executions, we find such wholesale murders as the following in abundance on the record. In 1612, twelve persons were condemned at once at Lancaster, and many more in 1613, when the whole kingdom rang with the fame of the "Lancashire witches;" in 1622, six at York; in 1634, seventeen in Lancashire; in 1644, sixteen at Yarmouth; in 1645, fifteen at Chelmsford; and in 1645 and 1646, sixty persons perished in Suffolk, and nearly an equal number, at the same time, in Huntingdon. These are but a few selected cases. The poor creatures, who usually composed these ill-fated bands, are thus described by an able observer:—"An old woman with a wrinkled face, a furred brow, a hairy lip, a gobber tooth, a squint eye, a squeaking voice, or a scolding tongue, having a ragged coat on her back, a spindle in her hand, and a dog by her side—a wretched, infirm, and impotent creature, pelted and persecuted by all the neighbourhood, because the farmer's cart had stuck in the gateway, or some idle boy had pretended to spit needles and pins for the sake of a holiday from school or work"—such were the poor unfortunates selected to undergo the last tests and tortures sanctioned by the laws, and which tests were of a nature so severe that no one would have dreamed of inflicting them on the vilest of murderers. They were administered by a class of wretches, who, with one Matthew Hopkins at their head, sprung up in England in the middle of the seventeenth century, and took the professional name of *witch-finders*. The practices of the monster Hopkins, who with his assistants moved from place to place in the regular and authorised pursuit of his trade, will give a full idea of the tests referred to, as well as of the horrible fruits of the witchcraft frenzy in general. From each town which he visited, Hopkins exacted the stated fee of twenty shillings, and, in consideration thereof, he cleared the locality of all suspected persons, bringing them to confession and the stake in the following manner:—He stripped them naked, shaved them, and thrust pins into their bodies

to discover the witch's mark; he wrapped them in sheets, with the great toes and thumbs tied together, and dragged them through ponds or rivers, when, if they sunk, it was held as a sign that the baptismal element did not reject them, and they were cleared—but if they floated (as they usually would do for a time), they were then set down as guilty, and doomed; he kept them fasting and awake, and sometimes incessantly walking, for twenty-four or forty-eight hours, as an inducement to confession; and, in short, practised on the accused such abominable cruelties, that they were glad to escape from life by confession. If a witch could not shed tears at command (said the further items of this wretch's creed), or if she hesitated at a single word in repeating the Lord's Prayer, she was in league with the evil one. The results of these and such like tests were actually and universally admitted as evidence by the administrators of the law, who, acting upon them, condemned all such as had the amazing constancy to hold out against the tortures inflicted. Few gave the courts that trouble. Butler has described Hopkins in his *Hudibras*, as one

"Fully empower'd to treat about
Finding revolted witches out.
And has he not within this year
Hang'd three score of them in one shire?
Some only for not being drown'd;
And some for sitting above ground."

After he had murdered hundreds, and pursued his trade for many years (from 1644 downwards), the tide of popular opinion finally turned against Hopkins, and he was subjected, by a party of indignant experimenters, to his own favourite test of swimming. It is said that he escaped with life, but, from that time forth, he was never heard of again.

The era of the Long Parliament was that, perhaps, which witnessed the greatest number of executions for witchcraft. *Three thousand persons* are said to have perished during the continuance of the sittings of that body, by legal executions, independently of summary deaths at the hands of the mob. Witch-executions, however, were continued with nearly equal frequency long afterwards. One noted case occurred in 1664, when the enlightened and just Sir Matthew Hale tried and condemned two women, Amy Dunny and Rose Callender, at Saint Edmundsbury, for bewitching children, and other similar offences. Some of the items of the charge may be mentioned. Being capriciously refused some herrings, which they desired to purchase, the two old women expressed themselves in impatient language, and a child of the herring-dealer soon afterwards fell ill—in consequence. A carter drove his waggon against the cottage of Amy Dunny, and drew from her some not unnatural oburgations; immediately after which, the vehicle of the man stuck fast in a gate, without its wheels being impeded by either of the *posts*, and the unfortunate Amy was credited with the accident. Such accusations formed the burden of the ditty, in addition to the bewitching of the children. These young accusers were produced in court, and, on being touched by the old women, fell into fits. But, on their eyes being covered, they were thrown into the same convulsions by other parties, precisely in the same way. In the face of this palpable proof of imposture, and despite the general absurdity of the charges, Sir Matthew Hale committed Amy Dunny and Rose Callender to the tender mercies of the hangman. It is stated that the opinion of the learned Sir Thomas Browne, who was accidentally present, had great weight against the prisoners. He declared his belief that the children were truly bewitched, and supported the possibility of such possessions by long and learned arguments, theological and metaphysical. Yet Sir Matthew Hale was one of the wisest and best men of his time, and Sir Thomas Browne had written an able work in exposition of *Popular Fallacies*!

This case occurred in 1664. For some subsequent years trials and executions were yet far from unusual.

Chief-Justices North and Holt, to their lasting credit, were the first individuals occupying the high places of the law, who had at once the good sense and the courage to set their faces against the continuance of this destructive delusion. In one case, by detecting a piece of gross imposture, Chief-Justice North threw into disrepute, once and for all, the trick of *pin-vomiting*, one of the most striking and convincing practices of the possessed. A male sorcerer stood at the bar, and his supposed victim was in court, vomiting pins in profusion. These pins were straight, a circumstance which made the greater impression, as those commonly ejected in such cases were bent, engendering frequently the suspicion of their having been previously and purposely placed in the mouth. The chief-justice was led to suspect something in this case by certain movements of the bewitched woman, and, by closely cross-questioning one of her own witnesses, he brought it fully out that the woman placed pins in her stomach, and, by a dexterous dropping of her head in her simulated fits, picked up the articles for each successive ejection. The man was found guiltless. The acquittal called forth such pointed benedictions on the judge from a very old woman present, that he was induced to ask the cause. "Oh, my lord," said she, "twenty years ago they would have hanged me for a witch if they could, and now, but for your lordship, they would have murdered my innocent son."

The detected imposture in this case saved the accused. It was under Holt's justiceship, however, that the first acquittal is supposed to have taken place, in *despite* of all evidence, and upon the fair ground of the general absurdity of such a charge. In the case of Mother Munnings, tried in 1694, the unfortunate pannel would assuredly have perished, had not Chief-Justice Holt summed up in a tone so decidedly adverse to the prosecution, that the verdict of Not Guilty was called forth from the jury. In about ten other trials before Holt, between the years 1694 and 1701, the result was the same, through the same influences. It must be remembered, however, that these were merely noted cases, in which the parties withstood all preliminary inducements to confession, and came to the bar with the plea of not guilty. About the same period, that is, during the latter years of the seventeenth century, summary executions were still common, in consequence of confessions extracted after the Hopkins fashion, yet too much in favour with the lower classes. The acquittals mentioned only prove that the regular ministers of the law were growing too enlightened to countenance such barbarities. Cases of possession, too, were latterly overlooked by the law, which would have brought the parties concerned to a speedy end in earlier days, even though they had done no injury to other people, and were simply unfortunate enough to have made compacts with the demon for the attainment of some purely personal advantages. For example, in 1689, there occurred the famous case of a youth, named Richard Dugdale, who sacrificed himself to the devil, on condition of being made the *best dancer* in Lancashire. The dissenting clergy took this youth under their charge, and a committee of them fasted and prayed, publicly and almost incessantly, for a whole year, in order to expel the dancing demon. The idea of this impostor leaping for a twelvemonth, and playing fantastic tricks before these grave divines, is extremely ludicrous. But the divines played tricks not less fantastic. They became so contemptuously intimate with the demon, as to mock him on account of salutory deficiencies. A portion of their addresses to him on this score has been preserved, but of too ridiculous a nature for quotation in these pages. If any thing else than a mere impostor, it is probable that Dugdale was affected with St Vitus's Dance; and this is the more likely, as a regular physician brought his dancing to a close after all. But the divines took care to claim the merit of the cure.

After the time of Holt, the ministers of the law went a step farther in their course of improvement, and

spared the accused in spite of condemnatory verdicts. In 1711, Chief-Justice Powell presided at a trial where an old woman was pronounced guilty. The judge, who had sneered openly at the whole proceedings, asked the jury if they found the woman "guilty upon the indictment of conversing with the devil in the shape of a cat?" The reply was, "We do find her guilty of that;" but the question of the judge produced its intended effect in casting ridicule on the whole charge, and the woman was pardoned. An able writer in the Foreign Quarterly Review remarks, after noticing this case, "yet, frightful to think, after all this, in 1716, Mrs Hicks, and her daughter, aged *nine*, were hanged at Huntingdon for selling their souls to the devil, and raising a storm by pulling off their stockings, and making a lather of soap! With this crowning atrocity, the catalogue of murders in England closes." And a long catalogue, and a black catalogue it was. "Barrington, in his observations on the statute of Henry VI., does not hesitate to estimate the numbers of those put to death in England, on this charge, at *THIRTY THOUSAND!*"

We have now glanced at the chief features in the history of witchcraft in England, from the enactment of the penal statutes against it. These statutes were not finally abolished till the middle of the eighteenth century, and unhappy consequences followed, in various instances, from their being left unrepealed. Though among the enlightened classes the belief in witchcraft no longer existed, the populace, in town and country, still held by the superstitions of their forefathers, and, having the countenance of the statute-book, persecuted the unfortunate beings whose position and circumstances laid them open to the suspicion of sorcery. The ban of public opinion told severely enough upon the comforts of such poor creatures, but the rabble occasionally carried their cruel and ignorant oppressions to a greater length. On the 30th of July 1751, an aged pauper named Osborne, and his wife, were seized by a mob in Staffordshire, dragged through pools, and otherwise so vilely misused, that the woman died under the hands of her assailants. The attention of the law, and the indignation of the humane, were aroused. One man, who had taken a prominent share in the brutal outrage, was condemned on trial, and executed. Immediately afterwards, the penal statutes against witchcraft were abrogated by the legislature, and the remembrance of them only remains, as a wonder and warning to the posterity of those who practised and suffered from them, as well as to mankind at large.

It must not be imagined, we may observe in conclusion, that the present generation has no need of such a warning, or is relieved by its increased enlightenment from all chance of falling into similar errors. The nineteenth century has witnessed such impostors as Johanna Southcott, Matthews, and Thom, and has seen a degree of enthusiastic and unhesitating credence given to their pretensions by many persons moving in a most respectable rank in society, which shows that the credulous spirit that created and supported witchcraft is not by any means extinguished. It is indeed a spirit only to be fully eradicated by such a universality of education and intelligence as can scarcely be expected to exist, excepting after the lapse of long-coming centuries of improvement. The subject which has been treated of here, has therefore a moral. In brief words, the world may learn from it the peril of encouraging the idea of the possibility of direct spiritual influences and communications in these latter days—a thing discountenanced alike by the lights of reason and scripture.

SPECTRAL ILLUSIONS.

The subject of spectral illusions, or, to use the common phraseology, apparitions or spectres, is now, in the estimation of scientific and properly informed men, one of the simplest and most intelligible to which the mind can be directed; while, to the ignorant, it still appears full of doubt and mystery. An apparition, spectre, ghost, or whatever it may be called, is vulgarly supposed to be a supernatural appearance—a thing occurring out of the

common order of nature. No particular time or place is assigned for the appearance; but we may observe that the time is usually evening or night, and the place solitary, or apart from the busy haunts of man. According to old theories on the subject, the person who declared that he had seen such an appearance was either set down as the fabricator of an untruth, or his story was fondly believed, and in the latter case the supernatural incident was added to the mass of credible history. We shall now endeavour to set this conflict of testimony and opinion to rights. In all cases, it is quite possible for the declarant to speak the truth as respects what he saw, or thought he saw, and yet that no real apparition may have occurred. The whole affair, as we shall explain, is simply a mental delusion, caused by some species of disease in the organs which affect the vision.

Mental and bodily disorder, organic or functional, is now allowed by physicians to be the basis of all kinds of spectral illusion. Organic disorder of the body is that condition in which one or more organs are altered in structure by disease. Disease of the brain, which involves organic mental disorder, is properly disease of the body, but enduring lunacy or fatuity, existing (if they can do so) without disease in the structure of the brain, may also be called organic disorder of the mind. These explanations will show what is meant by that epithet, as applied either to affections of the mind or body. Functional disorder, again, of the mind or body, is that condition of things where the healthy action of the organ or organs, in part or whole, is impeded, without the existence of any disease of structure. It may be said that violent excitement of the imagination or passions constitutes functional mental disorder; "anger is a temporary madness," said the Romans wisely. As for functional bodily disorder, temporary affections of the digestive organs may be pointed to as common cases of such a species of physical derangement. All these disorders, and kinds of disorders, may appear in a complicated form, and, what is of most importance to our present argument, the *nervous system*, on which depends the action of the *senses*, the power of *volition*, and the operation of all the involuntary functions (such as the circulative and digestive functions), is, and must necessarily be, involved more or less deeply in all cases of constitutional disorder, organic or functional. These powers of the nerves, which form the sole medium by which mind and body act and react on each other, give us a clue to the comprehension of those strange phenomena called spectral illusions, which depend on a combination of mental and physical impressions.

Organic mental disorder generates spectral illusions. Almost every lunatic tells you that he sees them, and with truth; they are seemingly present to his diseased perceptions. The same cause, simple insanity, partial or otherwise, and existing either with or without structural brain disease, has been, we truly believe, at the foundation of many more apparition-cases than any other cause. By far the greatest number of such cases ever put on record, have been connected with fanaticism in religious matters; and can there be a doubt that the majority of the poor creatures, men and women, who habitually subjected themselves, in the early centuries of the church, to macerations and lacerations, and saw signs and visions, were simply persons of partially deranged intellect? St Theresa, who lay entranced for whole days, and who, in the fervour of devotion, imagined that she was frequently addressed by the voice of God, and that our Saviour, St Peter, and St Paul, would often in person visit her solitude, is an example of this order of monomaniacs. That this individual, and others like her, should have been perfectly sensible on all other points, is a phenomenon in the pathology of mind too common to cause any wonder. We would ascribe, we repeat, a large class of apparition-cases, including these devotional ones, to simple mental derangement. The eye in such instances may take in a correct *impression* of external objects, but this is not all that is wanting. A correct *perception by the mind* is essential to healthy and natural vision, and this perception the deranged

intellect cannot effect. A three-footed stool may then become a kneeling angel. We would therefore have such persons regarded, not in the uncharitable light of impostors, but of poor creatures who mistook natural hallucinations for supernatural.

Undoubtedly, however, many of those cases of spectral illusions which have made the deepest impression on mankind, have not arisen from organic mental disease on the part of the sight-seers. The lunatic is apt to betray his condition, and, that once recognised, his visions become of no weight. We have then to turn to other causes of spectre-seeing; and, first, let us notice the mode of operation, and effects of certain *functional* disorders of the system, operating on the visual perceptions through the nerves. A bodily disorder, which ought in itself to afford a solution of all apparitions, is that called *delirium tremens*. This is most commonly induced, in otherwise healthy subjects, by continued dissipation. So long (say medical authorities) as the drinker can take food, he is comparatively secure against the disease, but when his stomach rejects common nourishment, and he persists in taking stimulants, the effects are for the most part speedily visible, at least in peculiarly nervous constitutions. The first symptom is commonly a slight impairment of the healthy powers of the senses of hearing and seeing. A ringing in the ears probably takes place; then any common noise, such as the rattle of a cart on the street, assumes to the hearing a particular sound, and arranges itself into a certain tune perhaps, or certain words, which haunt the sufferer, and are by and bye rung into his ears on the recurrence of *every* noise. The proverb, "as the fools think, so the bell tinks," becomes very applicable in his case. His sense of seeing, in the mean while, begins to show equal disorder; figures float before him perpetually when his eyes are closed at night. By day, also, objects seem to move before him that are really stationary. The senses of touch, taste, and smell, are also involved in confusion. In this way the disturbance of the senses goes on, increasing always with the disorder of the alimentary function, until the unhappy drinker is at last visited, most probably in the twilight, by visionary figures, distinct in outline as living beings, and which seem to speak to him with the voice of life. At first he mistakes them for realities, but, soon discovering his error, is thrown into the deepest alarm. If he has the courage to approach and examine any one of the illusory figures, he probably finds that some fold of drapery, or some shadow, has been the object converted by his diseased sense into the apparition, and he may also find that the voice was but some simple household sound converted by his disordered ear into strange speech; for the senses, at least in the milder cases of this sort, rather *convert* than *create*, though the metamorphosed may differ widely from the real substance. The visitations and sufferings of the party may go on increasing, till he takes courage to speak to the physician, who by great care, restores his alimentary organs to a state of health, and, in consequence, the visions slowly leave him. If, however, remedies are not applied in time, the party will probably sink under the influence of his disorder. The spectral figures and voices, being solely and entirely the creation of his own fancy, will seem to do or say any thing that may be uppermost in that fancy at the moment, and will encourage him to self-murder by every possible argument—all emanating, of course, from his own brain. The whole consists merely of his *own fancies bodied forth to him visibly and audibly*. His own poor head is the seat of all; there is nothing apart from him—nothing but vacancy.

Dr Alderson, a respectable physician, mentions his being called to a keeper of a public-house, who was in a state of great terror, and who described himself as having been haunted for some time with spectres. He had first noticed something to be wrong with him on being laughed at by a little girl for desiring her to lift some oyster shells from the floor. He himself stooped, but found none. Soon after, in the twilight, he saw a soldier enter the house, and, not liking his manner,

desired him to go away; but receiving no answer, he sprang forward to seize the intruder, and to his horror found the shape to be but a phantom! The visitations increased by night and by day, till he could not distinguish real customers from imaginary ones, so definite and distinct were the latter in outline. Sometimes they took the forms of living friends, and sometimes of people long dead. Dr Alderson resorted to a course of treatment which restored the strength of the digestive organs, and gradually banished the spectres. At the close of the account, it is said that the man emphatically expressed himself to have now received "a perfect conviction of the nature of ghosts."

Many additional cases from Hibbert, Abercromby, and other writers, might be quoted, in which the visual impressions and perceptions were in a similar way affected by the influence of digestive derangement. But as no doubt can rationally exist on the point, from the comparative commonness of the disease, no more proof need be brought forward. However, the inference naturally deducible from these facts is too important to be overlooked. Here we find, by unquestionable medical evidence, that a man walking about in apparent bodily health, and mentally sane, may nevertheless be subject to most distinct visitations of spectral figures, some of them in the semblance of *dead* persons. We find this, we repeat, to be within the range of natural phenomena. Now, is it not more likely, in those cases where wonderful apparitions are reported to have been seen, that the whole was referable to such natural causes, than that the grave gave up its dead, or that the laws of the universe were specially broken in upon in any other way? Even with only one such admitted source of spectral illusions as the malady alluded to, we should certainly err in passing it by to seek for explanations in supernatural quarters. But in reality we have *many* causes or sources of them, and to these we shall now look, in continuation of our argument.

Among the other varieties of bodily ailments affecting either structure or function, which have been found to produce spectral illusions, fevers, inflammatory affections, epileptic attacks, hysteria, and disorders of the nerves generally, are the most prominent. As regards fevers and inflammatory affections, particularly those of the brain, it is well known to almost every mother or member of a large family, that scarcely any severe case can occur without illusions of the sight to a greater or less extent. In hysteric and epileptic cases, also, where fits or partial trances occur, the same phenomena are frequently observed. But we shall not enlarge on the effects produced by the influence of severe and obviously existing maladies, as it is in those cases only where the spectre-seer has exhibited *apparent* sanity of mind and body, that special wonder has been excited. It is so far of great importance, however, to notice that these diseases do produce the illusions, as in most cases it will be found on inquiry that the party subject to them, however sound to appearance at the time, *afterwards* displayed some of these complaints in full force; and we may then rationally explain the whole matter by supposing the seeds of the ailments to have early existed in a latent state. A German lady, of excellent talents and high character, published an account some years back of successive visions with which she had been honoured, as she believed, by Divine favour. Dr Crichton, however, author of an able work on Insanity, found that the lady was always affected with the *aura epileptica* during the prevalence of the illusions; or, in other words, that she was labouring under slight attacks of epilepsy. Thus simply was explained a series of phenomena which, from the high character for veracity of the subject of them, astonished a great part of Germany. Another case, where functional bodily disorder of a different and very simple kind was present in an unrecognisable state, and produced extraordinary illusions, was the famous one of Nicolai, the Berlin bookseller. This individual, when in a perfectly fit state to attend to his ordinary business, was suddenly visited one day, when casually ex-

cited by some annoying circumstance, by the figure of a person long dead. He asked his wife, who was present, if she saw it; she did not. The bookseller was at first much alarmed, but, being a man of sense and intelligence, he soon became convinced of the illusory yet natural character of the spectra, which subsequently, for a period of two whole years, appeared to him in great numbers, and with daily frequency. "I generally saw (says he) human forms of both sexes, but they took not the smallest notice of each other, moving as in a market-place, where all are eager to press through the crowd; at times, however, they seemed to be transacting business with one another. I also saw several times people on horseback, dogs, and birds. All these phantasms appeared to me in their natural size, and as distinct as if alive; none of the figures appeared particularly terrible, comical, or disgusting, most of them being of an indifferent shape, and some presenting a pleasing aspect. The longer these phantoms continued to visit me, the more frequently did they return." They also spoke to him repeatedly.

These phantasms lasted, as we have said, two years. The issue is peculiarly worthy of note. Nicolai had in former years fallen into the habit of periodical blood-letting by leeches, but had ventured to stop the practice previous to the accession of the phantasms, and during their prevalence he had only been advised to attend to the state of his digestive organs. After they had endured for the time mentioned, it was thought fit to renew the blood-letting. At eleven in the morning, while the room was crowded with the spectral figures, the leeches were applied. As the bleeding slowly proceeded, the figures grew dimmer and dimmer, and finally, by eight o'clock in the evening, they had all melted into thin air, never to re-appear! This most remarkable case, the first in which any individual dared calmly to come forward and avow such an affection, at the risk of incurring the charge of insanity, was founded, we thus see, simply on a plethoric or surcharged state of the blood-vessels. Nicolai deserves great credit for the philosophic composure with which he recorded the phenomena presented to him; but his statement, which has often been republished in this country, seems defective in some points, and, from the interest of the subject, we may be pardoned for presuming to notice these. Generally speaking, he represents his spectral visitants as things which came and went, and assumed various shapes, and appeared in certain numbers, *uninfluenced* directly by himself. The total dependence which they had upon his own fancy of the *moment*, is not put clearly before us, though, by the truthful accuracy of his narrative, he unconsciously makes that fact apparent every instant. The surcharged state of the vessels was the fundamental cause of the phantasms, but his own passing fancies moulded them for the passing moment into shape, regulated their numbers, and gave them words. How could it be otherwise? The whole panorama was exhibited on his own retina, and the working brain behind was the manager and scene-shifter of the show.

Second-Sight.—Second-sight, taking the word in its common acceptation of supernatural sight-seeing, is one of the varieties of spectral illusion. Certain mental functions becoming diseased, the sense of sight is imposed upon by the appearance of things which are purely imaginary, but nevertheless supposed to be prophetic of future events. Idleness, solitude, insufficient diet, and an imagination led astray by ruminating too intensely on the causes of human weal and woe, may be assigned as the prevailing causes of the disease. The Lowland Scotch used occasionally to see *wraiths*, or spectral appearances of persons who were soon to quit this mortal scene; the Irish were also accustomed to the spectacle of *fetiches*; and the Highlanders had their *second-sight*—the whole, be it observed, being but a variety of the same mental disease and delusion.

Second-sight, however, has formed the subject of more regular profession than any other species of spectral frenzy. There were persons, who, possessing from infancy a defective mental constitution, or having a

taste for imposture, gave themselves out as habitual sight-seers, and were revered accordingly by their unsophisticated neighbours. According to the credulous accounts of second-sight, the power of the seer is a natural endowment, and cannot be acquired by communication, or in any other way. It is usually talked of by its possessors as a painful and troublesome gift, and one which they would gladly be rid of, if they could. Its vaticinations relate only to things to come, and not to past events. Young and old may alike possess the second-sight, and it is common, also, to men and women. The visions are sometimes predicative of good, and sometimes of evil. Occasionally, the vision simply gives indifferent tidings.

These are a few of the most common peculiarities attendant on this faculty. There are likewise numberless rules affecting its exercise, and the interpretation of its visions. If a vision occur by day, for example, the accomplishment of what it is supposed to predict will be speedy; if by night, less so. An exact proportion, indeed, is maintained in this respect—the morning vision being sooner fulfilled than that of noon; the latter more quickly than that of the afternoon; and so on. If the seer beholds a figure in a shroud, it is considered a sure sign of death to the party represented by the figure; and, according to the extent to which the shroud covers the body, the end will be quicker or slower. If a woman be seen at a man's left hand, it is a presage that she will be his wife, and this will be the case (say the true believers) though even both should then be married. If more than one woman be seen standing at a man's left hand, they will be married to him in rotation, as they stand nearer or farther from his arm. A seer often announces that such and such a guest will arrive at a certain hour, and, though a hundred miles away, the guest, it is said, will appear at the stated time. If a seer observe a vision of trees and crops in some spot or another, though perfectly barren and bare at the moment, wood and grain will, it is believed, there be seen in due time. A visionary house is beheld by the gifted eye, in a place where stone and lime were never laid, or expected to be laid. Yet there will the real house forthwith be seen. To see a seat as if vacant when one is sitting in it, is a presage of the party's death. The seer may behold crowds of people, or single individuals, and very frequently he meets imaginary funeral parties, and determines the coming decease by the apparent mourners.

These rules of vaticination are *said to be* unvarying. No ordinary person sees the vision while it is present to the seer, but the same vision often appears to two or more of the gifted, either while they are together or apart. The Highlanders believe that children and the lower animals, such as cows and horses, behold the appearances while they are before the seer. This is made plain, they say, in the case of the animals, by the trembling which seizes them at the moment; and frequently the children will cry, and, if asked the reason, will tell what unusual thing they behold or have beheld. It is almost needless to say, that the stories told to prove the truth of these notions, rest on no sure foundation, and that, at the best, the prophecies of the sight-seer only come to pass by chance.

Atmospheric Illusions.—Spectral or illusory appearances also take place from the power of refraction in the atmosphere. In certain conditions of the atmosphere, things at a distance, and really out of sight, as on the opposite side of a hill from the spectator, are represented in mid-air; but there is nothing supernatural in this—the whole is the effect of a simple cause. The following is an example of atmospheric illusion:—A gentleman and his servant, in the year 1744, beheld a troop of cavalry riding and performing various military evolutions on the side of Souter (or Sotra) Hill, in a spot so precipitous as to render it absolutely impossible for man or beast to maintain a footing. The servant had in the previous year observed a single horseman hunting in nearly the same place, and had then come to the conclusion that the sight was illusory, it being

impossible for a rider to cross a perpendicular precipice at speed. The troop of cavalry, therefore, was at once set down as an atmospheric deception, and numbers of persons of the district came to look on the extraordinary scene, which continued visible till nightfall. An explanation of the circumstance was afforded by the rebellion of the following year. Some party of rebels were most probably exercising in secret, in a spot where the evening sun so caught their figures as to reflect them on the acclivity of Souter Hill. The legend of the spectre of the Brocken in Germany, in like manner arises from the fact of the ground being favourable to the reflection of a visitor's figure against the evening sky. Our ancestors were occasionally alarmed with visions of armies fighting in the air, and similar illusions; had they been acquainted with the laws of atmospheric refraction, all would have appeared simple natural phenomena, having no relation to any future event, good or evil.

Dreams.—It has now been seen that there are various modes in which the system may be so disturbed as to produce spectral illusions, and that, in the majority of these cases, the parties subject to them might seem to be not only of sound mind, but in perfect bodily health. Another mode of explaining cases of this description may now be pointed out. Many of the apparitions which have been vouched for by those subjected to them, have certainly been neither more nor less than *vivid dreams*. A dream is a slight and ill-arranged action of the thinking faculties during a state of partial sleep; in other words, when we dream we are only thinking in a partially awakened state. The dream or the thought is in all cases but a momentary impression, perfectly natural in its operation; the state of mind which causes it being produced by temporary functional derangement: the stomach is usually less or more out of order. No dreams take place during sound sleep. In the greater number of instances, the half-awakened mind embarrasses itself with shreds of recollections of things formerly seen or thought of, and dressing these up in a new and fantastic form, a kind of drama is performed, having the semblance of reality. A servant girl living in a family where there were some phrenological busts, and, among others, a conspicuous one of Curran, awoke her bed companion one morning with the alarming information that the ghost of Curran stood at the foot of the bed dressed in a sailor's jacket, and having on his pale face the unwonted and unbust-like ornament of an immense pair of black whiskers. The other servant could see nothing, though the apparition seemed to her companion to remain visible for some minutes. On the tale being told, a pretty strong light was thrown on the matter. The master of the house had a yacht, and its sailors at that period were frequently about the premises. Going to bed much fatigued, and having her dreaming thoughts divided between her household duties and some gay whiskered beau of the yacht, the girl's fancy had dressed up Curran's bust, an object most familiar to her retina, in the way mentioned, giving him the sailor's person and whiskers as a fitting appendage. Had the object called up to the eye in this case, instead of being a bust of Curran, chanced to be a portrait of some wicked ancestor or ancestress of the family, as might easily have occurred from the greater comparative impression made on the mind by portraits of that cast, then should we have had a splendid instance of the preternatural appearance of a spirit stung by remorse, and haunting restlessly the scene of its mortal guilt. The girl, without imposture, might have conscientiously reiterated her conviction of the reality of the vision, and the possession of a haunted chamber would have most certainly been assigned to the mansion, inspiring such terror that renewals of the illusion might really have taken place in consequence. Where the whole affair is not a fiction in such haunted-chamber cases, some solution of this kind may be with certainty applied. The practice of believing that dreams are indicative or symbolic of coming events, is one of the silliest superstitions,

and is now very properly ridiculed by every rational mind.

MISCELLANEOUS SUPERSTITIONS.

During the seventeenth century, the belief in witchcraft, fairies, apparitions, charms, and every other species of supernatural agency, was universal in Britain, both among high and low, and clergy as well as laity. So ill instructed were the people in the art of tracing events to simple natural causes, that there appears to have been a continual liability to ascribe occurrences to the direct influence of good or evil spirits, but particularly to the devil. "Give me leave," says a respectable writer of that age, "here to relate a passage, which I received from a person of quality; namely—It was believed, and that not without good cause, that Cromwell, the same morning that he defeated the king's army at Worcester fight, had conference personally with the devil, with whom he made a contract, that to have his will then, and in all things else, for seven years after that time (being the 3d of September 1651), he should, at the expiration of the said years, have him at his command, to do at his pleasure, both with his soul and body. Now, if any one will please to reckon from the 3d of September 1651, till the 3d of September 1658, he shall find it to a day just seven years, and no more, at the end whereof he died; but with such extremity of tempestuous weather, that was by all men judged to be prodigious."* Such is a specimen of the egregious fallacies which passed for sound argument among our ancestors.

In Scotland, where religion assumed the garb of gloom and fanaticism, a belief in the personal appearance of devils was universal in the seventeenth century, and continued among the vulgar till within the last fifty years. The narrations of Satan's mean pranks, in assaulting ministers, waylaying travellers, and disturbing families while at worship, would fill a large volume. In the Rev. Mr Robert Law's "Memorials of Memorable Things, from 1638 to 1684,"† we find the following entry:—

"October 1670.—There was a devil that troubled a house in Keppoch, within a mile of Glasgow, for the matter of eight days time (but disappeared again), in casting pots, and dropping stones from the roof, yet not hurting any, like that which appeared in the west, in a weaver's house, a good man, about fourteen yeirs agoe, which did the lyke, and spoke to them audibly." The tricks of the devil, here referred to, as having taken place in a weaver's house in the west, about the year 1656, and which were implicitly believed by the most learned clergy of the time, are related at great length by Mr George Sinclair, professor of philosophy in the College of Glasgow, in his work, "Satan's Invisible World Discovered." The alleged events occurred at Glenluce in Wigtonshire, and would be too contemptible for quotation, if it were not desirable to show what paltry tricks were played off, and believed to be supernatural in those days. The family of the weaver, being vexed with noises and appearances, send for the neighbouring clergyman to allay the devil, betwixt whom and the worthy man a dialogue takes place, from which we extract a few passages:—"The minister returning back a little, and standing upon the floor, the devil said, 'I knew not these scriptures till my father taught me them.' Then the minister conjured him to tell whence he was. The foul fiend replied, 'That he was an evil spirit come from the bottomless pit of hell to vex this house, and that Satan was his father.' And presently there appeared a naked hand, and an arm from the elbow down, beating upon the floor till the house did shake again, and also he uttered a most fearful and loud cry, saying, 'Come up, my father—come up. I will send my father among you; see, there he is behind your backs!' Then the minister said, 'I saw,

indeed, a hand and an arm, when the stroke was given, and heard.' The devil said to him, 'Saw you that? It was not my hand, it was my father's; my hand is more black in the loof (palm). Would you see me,' says the foul thief, 'put out the candle, and I shall come batt the house (into the outer room) among you like fire-balls,' &c. The visit of the minister was unavailing. "About this time the devil began with new assaults; and taking the ready meat which was in the house, did sometimes hide it in holes by the door-posts, and at other times hid it under the beds, and sometimes among the bed-clothes and under the linens, and at last did carry it quite away, till nothing was left there save bread and water. The goodwife, one morning making porridge for the children's breakfast, had the wooden plate, wherein the meal lay, snatched from her quickly. 'Well,' says she, 'let me have my plate again.' Whereupon it came flying at her, without any skaith done." Any further extract from this ridiculous, though at one time universally believed, narrative, would be unnecessary. A modern police-officer would have effectually relieved "the afflicted family," by instantly discovering the performer of the tricks, and taking him into custody.

Besides the belief in ærial and terrestrial spirits, our credulous ancestors put faith in all kinds of romancing stories of river and sea demons. The more prevalent of these superstitious notions was a belief in mermaids and mermen, a class of creatures who lived in the sea, and had bodies half-human half-fish. Mermaids appear to have been much more common than mermen. The mermaid, we are told, possessed the body, from the middle upwards, of a beautiful female, with a head flowing with long yellow hair, which she incessantly combed with one hand, while she held a small mirror with the other. This female monster of the deep is described as having been a constant schemer of destruction to confiding navigators, or those who haunted unfrequented parts of the sea-shores.

Another of the vulgar superstitions of our ancestors was a belief common to nations of Germanic origin, that the corpse of a murdered person would bleed on being touched by the person who was guilty of the murder. Strange to say, this species of evidence of guilt was at one time admitted in the Scottish criminal courts. The following incredible instance was communicated to Sir Walter Scott, and is given in his *Minstrelsy of the Scottish Border* (vol. ii. p. 54.) "Two young men, going a-fishing in the River Yarrow, fell out, and so high ran the quarrel, that the one, in a passion, stabbed the other to the heart. Astonished at the rash act, he hesitated whether to fly, give himself up to justice, or conceal the crime; and in the end, fixed on the latter expedient, burying the body of his friend very deep in the sands. As the meeting had been accidental, he was never suspected, although a visible change was observed in his behaviour, from gaiety to a settled melancholy. Time passed on for the space of fifty years, when a smith, fishing near the same place, discovered an uncommon and curious bone, which he put in his pocket, and afterwards showed to some people in his smithy. The murderer being present, now an old white-headed man, leaning on his staff, desired a sight of the little bone; but how horrible was the issue!—no sooner had he touched it, than it streamed with purple blood. Being told where it was found, he confessed the crime, was condemned, but was prevented by death from suffering the punishment due to his crime." We need only add, that no evidence is given of the truth of this improbable tale, and it is utterly unworthy of belief.

Ignorance has often been justly termed the mother of superstition; wherever mankind are most ignorant, or least accustomed to trace events to their natural and proximate causes, there do all kinds of superstitious notions luxuriantly flourish. When the mind once allows that matters of ordinary occurrence may take place by the interference of invisible agents, such as spirits, apparitions, devils, and so forth, there is

* Walker's History of Independency.

† Edited by C. Kirkpatrick Sharpe, from the MS. Edinburgh: 1818.

obviously no limit to the actions they are supposed to perform. Hence the number of events believed to be ominous of evil in unenlightened society. The appearance of two or three magpies, the spilling of salt at table, the cracking of furniture, the howling of dogs, putting on the left shoe first, the ticking noise of an insect in rotten wood (death-watch), and a hundred other trifling occurrences, are imagined to be harbingers of evil. It is distressing to find, that notwithstanding the great advances of intelligence, a large portion of the people are still affected by the most absurd minor superstitions; for example, believing in the influence of charms, with as true a devotion to error as signalled our ancestors of the seventeenth century. The following instance of this species of credulity, given in a Norwich newspaper, April 1840, was mentioned as having lately occurred in that city:—"Children who are sickly are taken to a woman for the purpose of being cut for a supposed disease called the *spinnage*. The infants are on a Monday morning taken to this woman, who, for threepence, cuts through the lobe of the ear with a pair of scissors, then makes a cross with the blood upon the forehead and breast of the child. On the following Monday, the same barbarous ceremony is performed upon the left ear; and on the succeeding Monday the right ear is again doomed to undergo the same ceremony. In some cases it is deemed necessary to perform the operation nine times."

The occurrence in 1840 of a fatal disease in cattle, called the *murrain*, and which was susceptible of remedy by proper surgical means, led to the exposure of various superstitious observances among a respectable class of the rural population of England. In Northumberland, a fire kindled by rubbing together two pieces of hard wood, was carried about in an old shoe from one house to another, and thus passed through the country; with this a bonfire was lighted, and the cattle were made to pass through its smoke, which was supposed to render them invulnerable to the attacks of the disease.

In Scotland, cattle are the subject of scarcely less superstitious maxims. In many districts, if a cow has been seized with *phthisis pulmonalis*, or any inflammatory disorder, or if she has become *hide-bound*, or rumination has been accidentally stopped, the wise people called in to minister know but one explication of the mystery: the beast has got the *tail-ill*. This is an imaginary disorder supposed to reside in the tail, and to show itself by eating away the bone of that organ. To prove its presence, the cow-doctor will ask the owner of the animal to feel the tail near its extremity, and satisfy himself that the bone is "clean awa," the fact being that in that region there is only a soft cartilage. Under this miserable delusion, the people make incisions in the tails of cattle, into which they rub salt, soot, or horse turpentine, thus adding to the pains of the animal, without doing the least for the relief of the real malady. Often a considerable portion of the tail is cut off, by way of making the cure more certain. An educated veterinary surgeon of our acquaintance informs us that, in some cow-houses in his neighbourhood, there is not a cow with a tail above sixteen inches long.

One of the most remarkable charms now or very lately in use in Lanarkshire for the cure of illnesses in cattle, is a talisman of great antiquity, still preserved at Lee, a gentleman's house in that county, and popularly known as the *Lee Penny*. The following account of this ancient talisman is given in the *Picture of Scotland*, by R. Chambers:—

"Simon Locard of Lee accompanied the good Sir James Douglas to Palestine [in the fourteenth century], bearing the heart of King Robert Bruce enclosed in a locked case, on which account his name was changed to Lockhart, and he obtained for his armorial bearings a heart attached to a lock. Engaging in the wars of the Holy Sepulchre, this hero, who, at the death of Douglas in Spain, became the leader of the mission, had the good fortune to make a Saracen of rank his prisoner. The lady of the warrior came to pay his ransom, and

was counting out the money, when she happened to drop from her purse a small jewel, which she immediately hastened to pick up with an air of careful solicitude. Lockhart eagerly inquired the nature of the jewel, and learning that it was a mediatory talisman, refused to deliver up his captive, unless it were added to the sum previously stipulated. The lady was obliged to comply, and Simon brought it home to Scotland, where it has ever since continued in the possession of his descendants, perhaps the only existing memorial of the Crusades in this country. It is called the *Lee Penny*, on account of its being set in the centre of an old English silver coin. Triangular in shape, it measures about the third of an inch each way, and is of a dark red colour, but perfectly transparent. The nature of the stone cannot be determined by lapidaries, being apparently different in all respects from any known in this quarter of the world. To the edge of the coin a small silver chain has been attached, and the whole is deposited in a gold box which the Empress Maria Theresa presented to the father of the late Count Lockhart.

The *Lee Penny* did not lose its talismanic property on being transferred to a country of Christians. On the contrary, it has been all along, even till the present day, remarkable for medical virtue. It is especially sovereign in the diseases of horned cattle. The mode of administering it is this:—Holding it by the chain, it is three times plumped down into a quantity of water, and once drawn round—*three dips and a swirl*, as the country people express it—and, the cattle or others affected drinking this water, the cure is speedy and effectual. Even at this day, rife as the gospel is now said or supposed to be, people sometimes come from great distances with vessels, which they fill with water charmed in the manner described, and which they take home in order to administer it to their bestial. In the reign of Charles I., the people of Newcastle being afflicted with the plague, sent for and obtained a loan of the *Lee Penny*, leaving the sum of £6000 sterling in its place as a pledge. They found it so effectual, or were impressed with so high an opinion of its virtues, that they proposed to keep it, and forfeit the money; but the Laird of Lee would not consent to part with so venerable and so gifted an heir-loom. The laird of that time was a high Cavalier, and one of the charges brought against him by the party whom he had to oppose, was, that he effected cures by means of necromancy. One other remarkable instance of its efficacy is recorded. About the beginning of the last century, Lady Baird of Saughtonhall having been bit by a mad dog, and exhibiting all the symptoms of hydrophobia, her husband obtained a loan of the talisman; and she, having drunk and bathed in water which it had sanctified, got completely better. That this transaction really took place, seems indubitable, for an ancient female member of the Lee family, who died lately, remembered hearing the laird who lent the Penny to Lady Baird, describe how he and his dame had been invited to Saughtonhall, and splendidly entertained, in gratitude for the use of the talisman. Being now visited by an incredible number of persons, whose curiosity has been excited respecting it, Sir Charles McDonald Lockhart, the present proprietor, has adopted the idea of keeping an album in which their names are recorded. We have all seen the use made of it by the author of *Waverley*, in his fine chivalric tale, 'the Talisman.'

We need only add, what is here omitted to be mentioned, that the supposed influence of the Penny, like every similar charm, has been an entire delusion; and that if the cures were performed, as stated, something else than the charm of the talisman must have been the cause. In this, as in all similar traditions, the testimony is defective, every circumstance unfavourable to the superstition being suppressed.

DOMESTIC ECONOMY—COOKERY.

COOKERY is an art upon which so much of our daily comfort and health depends, that it is of the highest importance that it be well performed. Every housewife may not be able to procure the finest kinds of food, but every one has it in her power to make the most of that which she does procure. By a certain degree of skill and attention, very humble fare may be dressed in such a manner that it will almost rival the most expensive dishes, both in savouriness and nutritiousness. A good housewife suffers nothing to be lost or spoiled. Mere scraps, which a careless individual would perhaps throw away, are put to a proper use, and, by means of certain auxiliary seasoning, brought to table in a new and attractive guise. Even if little or nothing be absolutely saved by these economical arrangements, the dressing of food in a tasteful manner is a point of some importance. When a dish has a slovenly appearance, is smoked, underdone, or prepared with rancid or unclean seasoning, both the eye and the appetite are offended, which is a serious evil in itself, independently of the injury which may possibly be done to the stomach of the eater. In every respect, therefore, it is consistent with good judgment to prepare food for the table in the most tasteful and agreeable manner.

One of the chief points to be attended to in cookery is *cleanliness*—scrupulous cleanliness in every department of the business of the kitchen. The hands of the cook, in particular, should be always clean; that is, washed every time after doing any kind of work which has soiled them, or before proceeding to handle meat for dressing. She should also be careful in having her hair always neatly trimmed up, so that no loose hairs may drop into the dishes. The next point of regulation is to keep all the saucepans and other utensils perfectly clean in their inner parts, and also in the insides of the lids; carefully washing with hot water, and scouring when necessary. If the cooking utensils are not kept thoroughly clean, they will be very apt to taint the food prepared in them, and will certainly detract from the agreeable taste of the dishes. It is the duty of every housewife, either in her own person or by her deputy, the housekeeper, to see that these and all other rules affecting the cleanliness of the kitchen are attended to by servants, for she is understood to be responsible both for the wholesomeness and the tidy appearance of the dishes presented at table.

Another essential point in cookery is *attention*. Many persons think they have done all that is necessary, when they have fairly commenced or set a-going any particular process in cooking. They seem to imagine that they may safely leave a joint to roast by itself, or leave a pot with soup or broth to boil by itself, and that they have only to go back to the fire at a certain time, and they will find the things ready for dishing. Now, this kind of inattention is certain to spoil the best meat ever put to a fire. Some processes require much

less attention than others, but none can be properly performed if left long to itself. A good cook is pretty frequent in her visits to the fire, to see how the operation of dressing is going on, and seizes the proper moment in giving her assistance.

Perfection in the art of cookery is only attainable by lengthened experience, and a careful study of the qualities of meats, and the application of sauces and seasonings. It is chiefly in knowing how to make and apply sauces that a cook shows her skill. We therefore recommend this branch of the art to very careful attention.

KITCHEN ARRANGEMENTS.

A young and thriftily disposed housewife will, if possible, proceed to market herself, in order to lay in butcher-meat and other fresh provisions for her family. By this plan she will possess two advantages—that of selecting the best pieces, and of getting them at the lowest price. The frequency of her visits to the market will, of course, depend on the number of her family, and their taste as to the staleness or freshness of the meat to be purchased. If circumstances permit, it is advisable to purchase a whole week's provisions at a time, at least the chief things which will be required for the ensuing eight days. We would recommend a housewife to act upon a system in varying the kinds of meat which she buys, not only as they may be suitable to the seasons, but as calculated to promote the health of a family. It is of considerable consequence that food should be varied; indeed, sameness of diet will produce the most injurious effects, whatever be the quality of the food which is taken. Let the housewife, therefore, exercise a little ingenuity and judgment in her marketing expeditions, contriving to present at table a succession of different descriptions of animal and vegetable food; as, for example, sometimes meat roasted, and sometimes boiled or stewed; sometimes fresh meat, and sometimes salted; sometimes butcher-meat, and sometimes fish; and so on, according to taste and other circumstances. It does not necessarily follow, that, in thus varying the bill of fare, greater expense is incurred than if the same kind of articles were continually purchased.

The best meat is that which is moderately fat. If it be lean, or almost free of fat, it is an indication that the animal has been ill fed, and that the meat will prove tough and tasteless. Avoid lean beef—it forms wretched fare, and will be dear at any price. The fat of good beef is slightly yellowish; the fat of good mutton is pure white. The flesh of both beef and mutton should be of a clear red colour. The mutton of black-faced sheep, or Southdowns, is the most tender or sweet, and may be known by the shortness of the shank. Mutton is in perfection at between four and five years, but is seldom to be had older than three years. Cow and bull beef are considerably inferior to ox beef.

In choosing lamb, select that which has a delicate appearance and is perfectly fresh. Young veal has a dark and flabby look, and is tasteless when dressed. Veal is best when the animal is between four and six months old. The flesh is then white and delicate, and is firm in the fibre. Pork should be white and delicate like veal, and thin in the skin. Lamb, veal, pork, and all other young or white meat, should be fresh, and not bought long before being used.

Fowls, ducks, and other feathered animals, should be purchased young, and should all be firm and fleshy to the touch. If the thin bone which projects over the belly feel hard on being handled, the animal is old; if it feel soft like gristle, the animal is young. This is the safest rule for choosing young feathered animals. The age of game is of little consequence, as it is hung for a considerable length of time before dressing.

All kinds of fish, except salmon, should be purchased as fresh as possible. Freshness in cod, haddock, and generally all fish, is indicated by stiffness in all parts of the body, and a clear glittering appearance in the scales. Freshness is likewise known by the smell. If there be the least staleness, the fish has an offensive odour. As tricks are sometimes performed with the eyes and gills, freshness of appearance in these is not to be trusted.

It is very difficult to ascertain when eggs are perfectly fresh. There are different rules on the subject, but they are all liable to failure. One mode of judging, is to hold the egg between the eye and the light of a candle, shadowing the eye with the hand; if the appearance is universally luminous without any cloudiness, the egg is fresh; if cloudy or not uniformly luminous, it is probable that the egg is unfit for use.

Butter may be easily selected by the taste and the smell; but in buying both eggs and butter, it is best to deal with a person on whom you can rely, as it is troublesome to be continually seeking out and examining these articles to determine their freshness.

Good ham and bacon have a fresh savoury smell; the fat is white, and free from any yellowness. If it be yellow, reject it, as it will soon become rank and rusty.

Flour for culinary purposes should be new and fresh. Old flour is liable to spoil and become full of animal life, in which condition it is unfit for pastry and other dishes. The best kind of salt for the kitchen is that which is purchased in lumps and cut down.

Keeping Meat.—A larder is a place where fresh meat is kept till it is in a fit state for being cooked, and where cold meat or any other kind of food may be set aside. The larder should be cool and dry, with the outer air playing freely through it. It should also be impervious to vermin or insects, particularly flies. Two or three shelves, and a few strong iron hooks for hanging the meat, are the only furniture.

Beef and mutton are always improved by hanging some time after being killed before they are cooked. The length of time which they may be kept depends on the state of the weather. The best weather for the purpose is when the atmosphere is cool, clear, and dry; in such circumstances, beef and mutton may hang from four to ten days; mutton, if well managed, may hang a fortnight or even three weeks. A moist thick atmosphere is the worst for keeping meat; and when it occurs, great care must be taken with the contents of the larder. The meat should be wiped daily with a cloth, to free it as much as possible from the moisture that gathers upon all meat when kept for many days. In all cases, fresh meat should hang from a hook, and not be laid on a plate.

In most instances, fresh meat is cooked too soon after being killed, a circumstance perhaps arising from the general deficiency of proper larders, and the dread of the meat being spoiled. The consequence is, that, instead of being tender and palatable, the meat is tough and disagreeable, and not so nutritious or so easily digested as it ought to be.

While beef and mutton may with great propriety be kept some days to become tender, veal, lamb, and pork

(being young or white meat), will not endure keeping more than a day, or two days at the utmost. Game may be kept for two or three weeks, that which is feathered being kept with the feathers on, and hares being embowelled or paunched. A fowl will keep a week, and a turkey a fortnight. A goose will not keep above nine or ten days. Great care should be taken in picking feathered animals which have been kept, for their skin will in such a case be easily torn.

Keeping Cold Meat.—When newly cooked meat is brought from table, and has to be set aside for after use, put it on a clean dry dish; if any liquor or gravy be left about it, the meat is apt to become sour. The drier and more cool that cold meat is kept, the better. Cold meat is always best when it has not been cut while warm, as in that case the juices have not run out, but remain to enrich the meat.

Keeping Vegetables.—Vegetables of all kinds should be used as soon after gathering as possible. They begin to ferment, and to lose both their flavour and their wholesomeness, very shortly after being taken from the ground. When they have necessarily to be kept for a day or two, place them in a perfectly dry and cool situation, but not exposed to currents of wind. Keep also each kind of vegetable separate from another, to prevent contamination of flavour. They should never be washed or placed in water till immediately before being used.

Kitchen Range.—The most important part of the cooking apparatus is the range or grate. In general, too little care is bestowed by young persons when setting up housekeeping, in making a proper choice of this article. A common error consists in buying ranges which are too large, and which consume a great deal more fuel than is necessary, either for cooking or giving forth heat. One of the chief points in housekeeping, is to cook victuals with the smallest possible quantity of coal. To effect this desirable object, let the range be of a small size, consisting of a fireplace in the centre, large enough for only one vessel, with an oven upon the one side and a boiler on the other; the boiler also going round the back of the fireplace; the top of the whole to be flat. The fire in the grate will thus heat the water in the boiler without any trouble, and will in a great measure render the use of a kitchen kettle unnecessary. The fire will also assist greatly in heating the oven, which at least will at all times heat dinner plates; and if required for baking, a very small quantity of live coal put into the furnace beneath will be sufficient. A range of this description, which will cost about £4, 10s., will at once roast meat in front, boil water, bake a dish in the oven, though not so well as by a separate or large oven, and keep boiling or simmering at least three vessels on the fire and top of the boiler and oven. Care should be taken to have the range set in such a manner that the smoke from the oven may pass upwards behind to the chimney. By being altogether of iron, this kind of range requires very little building.

The main advantage of such a range is the constant and large supply of hot water which it affords. Every one experienced in family arrangements knows that a house should never be without hot water, as it may be wanted at a single moment's notice for various purposes; among others, for hot fomentations, bathing of infants, and so forth. A life may be saved by the ready supply of this article alone.

Boiling and Stewing Vessels.—The choice of these vessels will depend on the taste and judgment of the purchaser. The best kind (called goblots in Scotland, and saucapans in England) are those made of iron, well tinued inside, and these may be had of all sizes. It is convenient to have one or two of the very smallest dimensions, made of block tin, and also to have several to be kept for delicate stews or preparations. It is likewise advantageous to have a few shallow saucapans to be used for stews, or where little liquor is required. Also, one large fish kettle, with a flat drainer to place below the fish in boiling, and for lifting to the dish when

done. All the vessels should have tightly-fitting tin or iron covers.

Roasting and other Utensils.—Roasting is always best performed with a twirling hook and bottle-jack. A spit spoils a small piece of meat, and is an instrument which, with the jack that moves it, should never gain an entrance into the kitchen of a family in the lower or middle ranks of life. The bottle-jack, which is in every respect preferable, should be attached to the top of a tin screen of the usual semicircular form. This screen reflects the heat upon the meat, and aids the roasting. Sometimes the screen has the effect of drawing out the smoke from the chimney; when this is the case, have the upper part of the screen taken away, and suspend the jack from a projecting arm or rack on the chimney-piece. This arm, which may be folded back when not used, is made of brass, and may be had for about eighteenpence from any London or other ironmonger. A tin box with an open side, called a Dispatch, and resembling a bachelor's oven, is a most useful utensil in a kitchen for baking small puddings or potatoes. Two other main utensils for cooking are a gridiron and frying-pan.

ROASTING MEAT.

Meat is roasted by being exposed to the direct influence of fire. This is done by placing the meat before a fire, and keeping it constantly in motion, to prevent scorching on any particular part. Roasting is generally considered to be the least thrifty mode of dressing meat; but much of the loss may be avoided by care and cleanliness in saving the dripping for other processes of cookery.

Dripping.—Roast beef yields a dripping, which is a valuable article in the economy of the kitchen. It should be removed from the pan beneath the meat before it becomes overheated, or scorched, by the fire, leaving sufficient for basting. Dripping is prepared for future use in the following manner:—As taken hot from the dripping-pan, pour it into boiling water, when all particles of cinder or other improper matter will fall to the bottom, and leave the pure fat on the surface. Collect these cakes of fat, and by heating them in a jar, placed in a saucepan of boiling water, the whole will become a solid mass, and may be thus put aside for use. This process not only purifies dripping, but gives it a clear white colour. A little salt must be infused, to assist in preserving it.

The dripping from mutton, being tallowy, is little used in cookery, and the dripping from most other kinds of meat and poultry is deemed equally valueless. The dripping from lamb may be preserved for use in frying fish, or making pie-crust.

To roast Beef.—The best piece of beef for roasting is the sirloin. If the suet be not required, it may be ordered to be cut off before purchasing the joint; a small piece of suet is all that is requisite for the purpose of basting. Do not wash the meat, unless when it is musty, as already directed. Wipe it quite dry, and hang it on the hook of the jack, in the way most advantageous for being operated upon uniformly by the fire. Handle it as little as possible. At first, place it at such a distance from the fire that it may be warmed thoroughly before being scorched on the outside. The fire must be quite clear and brisk. It is customary to allow a quarter of an hour for every pound of the meat. While roasting, baste it very frequently with its own dripping. In dishing, pour a little boiling water and salt over it for a gravy. A well-roasted joint ought to have a nice rich brown tinge all over, and this is to be obtained only by careful basting, attention to the fire, and removing at the proper time, when experience tells that the joint is "done." Garnish with scraped horse-radish.

To roast Mutton.—The best parts of mutton for roasting are the leg (called in Scotland the gigot), the shoulder, and the loin. The piece may be kept longer than would be desirable for mutton for boiling. It should have a clear and brisk fire. A leg will take

two hours to roast; but this, as well as the time for roasting the other parts, must be regulated by the fire and the weight of the meat, and can be learned only by attention. The joint of mutton should be basted the same as beef, with its own dripping. A gravy for roast mutton, as in the case of beef, may be made by pouring a little hot water and salt over it; if wanted of a richer quality, a gravy sauce may be made from beef, as directed under the head SAUCES. Most persons prefer mutton "well done." In roasting the loin, take away the fat surrounding the kidney, otherwise the dish, on being brought to table, will, when cut up, be floated with oil. The back-ribs and loin of mutton ought to be well jointed or cut before being put to the fire.

To roast Venison.—Venison is roasted in the same manner as mutton, but requires longer time at the fire. It is such a dry meat, and the fat is so easily melted, that it should be covered with buttered paper, and well basted. Serve with a good gravy and currant jelly.

To roast Veal.—The best parts of veal for roasting are the fillet, the breast, the loin, and the shoulder. The fillet and the breast should be stuffed, particularly the fillet; the stuffing to be composed of crumbs of bread, chopped suet and parsley, a little lemon peel, and pepper and salt, wet with an egg and a little milk. The piece should have a slow fire at first, and will require longer time to dress than beef or mutton. Let it be well basted with butter when there is not sufficient dripping from the joint. The gravy for roast veal is either the usual hot water and salt, or thin melted butter, poured over the meat.

To roast Fillet of Veal.—The fillet of veal, which is the thick fleshy part of the hind leg, requires care in the preparation for roasting. The knuckle or bone must be cut out neatly, without disfiguring the joint; then stuff the flap, as above; roll it up firmly, and bind it with tape or string. Allow the stuffing in this, as in all other cases, room to expand in dressing. Cover the ends with buttered paper, and baste the piece frequently with butter. Take off the paper a short time before the meat is done. Gravy as above. This dish may be garnished with sliced lemon.

To roast Lamb.—Lamb also requires to be well roasted. It is usually dressed in quarters; all parts, particularly the spinal bone, should be well jointed or cut by the butcher or cook; and the ribs of the fore quarter broken across the centre, in order to accommodate the carver. In roasting, baste, as already described, with its own dripping. The gravy for lamb may be the same as for beef or mutton, namely, hot water and salt poured over it; it is also customary to serve it up with mint sauce in a small tureen.

To roast Pork.—Pork requires a longer time in roasting than any of the preceding meats. When stuffing is to be used, it must be composed of chopped sage and onion, pepper and salt. The pieces should be neatly and well scored in regular stripes on the outer skin, to enable the carver to cut slices easily. Before putting to the fire, rub the skin with salad oil, to prevent its blistering, and baste very frequently. The basting may be done by rubbing it with a piece of butter in a muslin bag, where there is not enough of dripping. The gravy for pork may be the same as for other joints, hot water and salt poured over it on the dish. It is considered an improvement to have apple-sauce served in a small tureen, as it assists in overcoming the richness or lusciousness of the meat, and imparts a slight acidulous flavour.

To roast Sucking-Pig.—The animal being properly prepared and cleaned by the butcher, the cook will proceed to cut off the feet, and fill the inside with a stuffing composed of chopped sage, crumbs of bread, butter, pepper, and salt. The quantities of these respective ingredients must be regulated by the judgment and taste of the individual. The principal ingredient is bread. The stuffing being mixed and filled in, sew up the slit. No skewering is required. In roasting, baste with butter, as directed for pork. The time for roasting will be from two to three hours, according to

the size. The skin should be crisp, and nicely browned. Before bringing to table, split down the back from head to tail, and lay it flat in the dish with the skin side uppermost. The head is cut off, and, being split in two, a half is laid at each end. The brains are taken out, and, with the liver, which has been previously boiled and finely chopped, is mixed either with beef or veal gravy in a small tureen. Apple-sauce is also used. This is the most approved mode of serving up sucking-pig.

To roast Bullocks' Heart.—Wash the heart well, freeing it completely from blood. Then fill all the openings at the top or broad end with a stuffing composed of crumbs of bread, chopped suet, parsley, pepper and salt, moistened with an egg and a little milk. Suspend with the pointed end downwards. An hour and a half or two hours, according to the degree of heat, will cook the dish. It should, however, be well done. Send to table with beef gravy.

To roast Pigeons.—Pick and draw them well, and truss, keeping on the feet. Make a stuffing of the liver chopped, crumbs of bread, minced parsley, pepper, salt, and a little butter; put this inside. Make a slit in one of the legs, and slip the other leg through it. Skewer and roast them for half an hour, basting them well with butter. Serve with brown gravy in a small tureen. Some serve roast pigeons, or game, with toast bread beneath them, and bread sauce.

To roast Fowls.—Pick, draw, and singe them. A fowl should be so cleanly or well drawn as to require no washing. Take care not to break the gall-bag in drawing; if the gall be spilled, it will communicate a bitter taste to every part it touches. Press down the breast-bone. Break the legs by the middle of the first joint, drawing out the sinews, and cutting of the parts at the break. It being proper that roast fowls should have a neat appearance at table, it is customary to truss them, that is, to fix their legs and wings in a particular position. This is done by fixing down the knees of the animal close to the tail by a skewer or piece of string, leaving the stumps of the legs projecting. The pinion ends of the wings are then turned round on the back, the liver being placed as an ornament in one wing and the gizzard in the other. Cut the head off close to the body, leaving a sufficiency of the skin to be tied or skewered on the back. Baste well with butter for some time after putting to the fire. Suspend neck downwards. The time of roasting will vary from half an hour to an hour, according to the size of the chicken or fowl. When fowls are large, they are frequently stuffed like turkey.

Serve roast fowls with melted butter or gravy sauce. Before sending to table, remove all skewers and strings which may have been used in trussing. This, which should be done in all cases of serving dishes to table, is too frequently neglected, and shows slovenliness in cookery. Fowls and all other feathered animals are served with the breast upwards.

To roast Turkey.—Pick, draw, and singe the turkey well. Press down the breast-bone, and follow all the directions given for trussing fowls. The breast should be stuffed with crumbs of bread, minced beef suet or marrow, minced parsley, a little nutmeg, pepper and salt; wet it with milk and egg; a little sausage meat may also be added. On finishing, sew up the orifice or neck. Before putting to the fire, cover the breast with a sheet of writing-paper well buttered, to preserve it from scorching, and which may be removed a short time before taking from the fire, to allow the breast to be browned. Baste well with butter. A turkey will take from an hour and a half to two hours. Serve with gravy sauce and bread sauce.

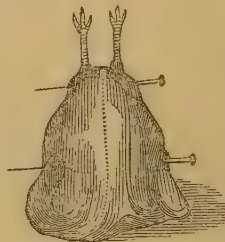

To roast Partridges.—Pick, draw, singe, and clean these birds the same as fowls. Leave the head on. Make a slit in the neck, and draw out the craw. Twist the neck round the wing, and bring the head round to

the side of the breast. The legs and wings may be trussed in much the same manner as fowls. The feet are left on, and crossed over one into the other, as seen in the annexed figure. Baste well with butter before a clear fire. When about half done, dust a little flour over them to be browned. A partridge will take from twenty minutes to half an hour, and a pheasant three quarters of an hour. Serve on toasted bread, with gravy and bread sauce; the toasted bread may be dipped in the gravy.

Grouse and blackcock should be dressed and served in the same manner; the head being trussed under the wing. Snipes and woodcocks are not drawn.

To roast Goose.—Pick, draw, and singe the goose well. Cut off its head and neck. Take off the legs and wings at the first joint. The portions of the legs and wings that are left are skewered to the sides. Stuff with chopped sage and onion, and crumbs of bread, with pepper and salt. The skin of the neck must be tied securely, to prevent the gravy from running out. Paper the breast for a short time. A goose does not require so much basting as fowl or turkey, for it is naturally greasy. It will require from two hours to two hours and a half in roasting. It ought to be thoroughly done. Serve with gravy sauce and apple sauce. The liver, gizzard, head, neck, feet, and the pinions of the goose, form what is termed the *giblets*, and compose a good stew or pie.

To roast Ducks.—Pick, draw, and singe them well. Take off the head. Dip the feet in boiling water to take off the outer yellow skin. Truss them neatly, turning the feet flat upon the back. Stuff as in the case of goose, and serve with the same sauces. A duck requires about an hour in roasting.

To roast Pheasants.—

Pick, singe, and draw them, the same as fowls. Truss them by twisting the head round one of the wings, and turning both wings on the back. The legs are fixed on each side, much in the same manner as in a roast fowl, the feet being left on, as here represented. Serve with beef gravy and bread sauce.

To roast Hare.—A hare will keep with the skin on it, and paunched, for about three weeks in cold weather. It is then fit for roasting. First cut off the feet, and commence drawing off the skin at the hind legs, proceeding along the body to the head. Be careful not to tear the ears in skinning them. Soak and wash well in several waters, and then wipe quite dry. Stuff with crumbs of bread, chopped parsley, a bit of beef or veal suet chopped finely, a little grated

lemon-peel and nutmeg, a piece of liver boiled and finely chopped or grated, and pepper and salt; the whole moistened with an egg, a little milk, and a spoonful of ketchup. The skin of the belly afterwards to be sewed. Commence trussing, by placing the hind and fore legs flat against the sides. To make the hind legs lie flat, the under sinews must be cut. Fix the head between the two shoulders, on the back, by running a skewer through it into the body. In roasting, suspend head downwards. It may be basted first with milk, afterwards with butter, flouring it lightly. It will require from an hour and a half to two hours. The hare is dished back upwards, as represented above, and served with a dish of rich beef gravy, and a dish of currant jelly.

BAKING MEAT.

Meat is prepared for baking in the same manner as for roasting. It should be placed in a deep dish for receiving the fat which flows from it; not laid, however, on the sole of the dish, but raised on a stand, to prevent the grease soaking into it. Small iron stands are made and sold for this purpose. Few dishes are so good when baked as when roasted, the meat being so liable to be shrivelled for lack of basting. Perhaps the only dishes which are better baked than roasted, are bullocks' heart and leg of pork, because in roasting they are liable to be scorched on the outside before they are thoroughly cooked in the inner parts. In baking a heart, place it in a stand in a dish with the point downwards; a piece of writing-paper, buttered, may be placed over it, to keep the stuffing from drying. The sauce used is beef gravy.

BROILING.

Broiling is the rapid cooking of any kind of animal food, by the influence of fire. The apparatus required in broiling is very simple, and consists only of a gridiron, which should have small bars, and be kept thoroughly clean, not only on the tops, but on the sides of the bars. Let it be heated on the fire for a few minutes before placing the meat on it. If the bars, when warm, be rubbed with a piece of brown paper, the meat will be prevented from sticking to them. The operation of broiling requires a clear strong fire, with no smoke. In almost all cases, the meat ought to be frequently turned, which may be best done by a pair of small tongs; a fork should on no account be used in turning, for it breaks the skin of the meat, and allows the gravy to run out. Broiling possesses the peculiarity of being applicable only to meat which is to be eaten immediately on being dressed. This is an advantage when expeditious cooking is required, but a disadvantage when there is any uncertainty as to the time at which the meat is to be eaten.

To broil Beef-Steak.—A beef-steak is the most suitable of all kinds of meat for broiling, and is a dish universally relished. There are several parts of beef used for steaks, but in every case it should not be too newly killed. The best steak is that cut from the rump (called in Scotland the *heuk-bone*), because it is the most juicy and well flavoured. Steaks should be cut in slices of from three quarters of an inch to an inch in thickness, and into pieces of a convenient size for turning. Some persons dust the steaks with pepper before putting them to the fire, by which means the flavour of the pepper is infused through the mass. When placed on the gridiron, turn them very frequently; it is said, indeed, that the steaks should never be at rest, but this is carrying matters to an extremity. It is impossible to state any exact length of time to be employed in cooking a steak, for much depends on the tenderness and thickness of the meat, and the strength of the fire. The taste of the individual who is to eat the steak must also regulate the length of time; because, while some prefer steaks in a half-raw state, others wish them to be well done. When cooked to the extent which is required, place the steak on a hot dish, and, after rubbing the steak with a little good fresh butter, sprinkle it with a little fine salt.

Beef-steaks should be carried to table immediately on being dressed, and eaten forthwith, in order to be in perfection. Every moment they stand, they lose a portion of their flavour and juice. When sauce is required, either mushroom or oyster sauce may be used.

To broil Mutton Chop.—Mutton chops should be cut from the middle of the hind loin, and about the same thickness as steaks. They are broiled in the same manner as steaks, and require equal attention. No butter is to be used on dishing, as the chop is sufficiently fat of itself. Sprinkle a little salt on it, and carry to the table immediately. Mushroom sauce may be used.

To broil Fowls and Pigeons.—Clean and prepare them as for roasting; then split them down the back, laying

them quite flat. Dust with pepper. They should be broiled more slowly than steaks or chops, being thicker, and requiring to be more thoroughly dressed. Rub occasionally with a little butter, to prevent the skin from cracking. In no case should the skin be taken off before broiling. On dishing, sprinkle with salt.

Various sauces are used—parsley and butter, melted butter, beef gravy, or mushroom sauce.

FRYING.

Frying is as expeditious a mode of cooking as broiling, requires less activity and care, and is more thrifty. The thriftiness of frying is a point of material consequence, and may be thus explained. It affords a ready means of dressing in a savoury manner many odd pieces of uncooked or cold meat, thereby saving that which might otherwise have been thrown away as useless. A skilful housewife, with the aid of a frying-pan and some unexpensive vegetables, such as onions and potatoes, along with a slight seasoning, will make a small portion of meat dine a large family.

A frying-pan should be of malleable, not of cast, iron. It should also be thick in the bottom, and of an oval form. It should always be kept clean, by being washed with boiling water, but not scoured. In all cases of using, a small piece of dripping, butter, or lard, must be put into it and melted, to prevent the meat from adhering. In frying all meats, excepting those which are sufficiently fat in themselves, it is necessary to use some kind of grease or fat. The best fat for this purpose is lard, which is more economical, and less likely to burn than butter. When lard is not employed, the best substitute for it is dripping.

To fry Beef-Steaks.—Cut the steaks as for broiling, and, on being put into the pan, shift and turn them frequently. Let them be done brown all over, and placed in a hot dish when finished. Gravy may be made by pouring a little hot water into the pan after the steaks are out, and the fat poured away, with a little pepper, salt, ketchup, and flour. The gravy so formed is to be poured into the dish with the steaks. Serve to table immediately.

If onions be required along with the dish, cut them in thin slices, and fry them till they are soft. They should be fried after the steaks, and merely with part of the fat in which the beef has been fried.

To fry Mutton Chops.—They require to be cut in the same manner as for broiling, and may be dressed according to the preceding directions for steaks. None of the grease which flows from the chops is to be used along with them, and the whole must be poured away before preparing the gravy.

To fry Veal Cutlets.—Veal cutlets form a delicate dish, and should be fried with butter. The best cutlets are from the fillet, because they are free from bone; the fore or hind loin—that is, the back-ribs or loin—may be used, but the bone must be cut away, which causes a waste. Cut them half an inch in thickness. They require to be dressed slowly and thoroughly, and should be of a light brown tinge when finished.

Another and more tasteful way of dressing cutlets, is first to dip them in a beat egg and then strew them with crumbs of bread, and parsley chopped very fine, along with pepper and salt, after which put them in the pan. They will require more lard or dripping this way than when fried plain.

Gravy may be made for cutlets the same as for fried steaks, but add a little juice of a lemon, and skim the gravy before pouring it over the cutlets.

To fry Lamb Chops.—Lamb chops may be either simply fried in the same manner as mutton chops, or dressed with egg and crumbs of bread (but with no parsley), as in the case of cutlets. Gravy made in the pan, as for fried steaks.

To fry Pork Chops.—Pork chops should be cut rather thin, and be thoroughly dressed. They may be either simply fried in the same manner as chops, or fried after being dipped in egg, and sprinkled with crumbs of bread, and sage and onion finely chopped. No gravy is ex-

pected with pork chops. If any sauce be used, it must be apple sauce.

To fry Beef or Pork Sausages.—All sausages are fried alike, and require to be dressed very slowly. Before being put into the pan, they should be pricked in several places with a fine fork, to prevent their bursting by the expansion of the air within.

It is common in England to bring fried sausages to table, neatly laid out on a flat dish of mashed potatoes. The sausages and potatoes are helped together. They may also be laid in links on toasted bread, and garnished with poached eggs round the dish.

Fried sausages are sometimes used for garnishing roast turkey.

To fry Tripe.—The tripe must be washed well, and boiled till tender. Take the thickest parts, and dry them well with a cloth. Make a thick batter of egg, flour, and milk, seasoned with salt, and for those who wish it, a little minced onion. Dip the tripe into the batter so formed, after which fry in lard or good fresh dripping, of which there must be a sufficiency in the pan almost to cover the tripe. Let it be done to a light brown. Garnish with fried parsley.

To fry Parsley.—Parsley is fried only for garnishing. It must be thoroughly dried, and fried in hot butter or dripping. After frying, lay it on a sieve before the fire for the fat to drain from it; after which, place it round the edge of the dish.

To fry Bacon, or Ham and Eggs.—The bacon should be cut very thinly in slices not more than a quarter of an inch in thickness. The best bacon is that which is alternately streaked with fat and lean. No butter or dripping is required in the pan in frying bacon, which does not need much dressing, and is soon prepared. When done, take the slices from the pan, and place them in a hot dish before the fire. Have the number of eggs required previously broken, each in a separate cup, and place them gently in the pan, so as to preserve them in a round flat shape. Let them remain in the pan till the white is set, and take them out carefully with a slice, and place them on the bacon. The tasteful appearance of this dish is spoiled, if the eggs be either broken or ragged, which is very apt to be the case if they are not previously put into cups.

To fry Collops.—The difference betwixt this dish and fried steaks, is, that the collops or pieces of meat are partially stewed, as well as fried. Cut the meat thinner than for broiling, and put the slices in a pan along with a large piece of butter and sliced onions. Cover it close, and when the meat is sufficiently dressed, add a little hot water and ketchup to the liquor already in the pan.

BOILING.

Boiling is the preparation of meat in water, and it is necessary that the vessel employed be large enough to allow the meat perfect freedom; if it be cramped, and have only a little water, it will be stewed, not boiled. In all cases of boiling, there must be a sufficiency of water to cover the meat. In boiling meat there is less waste than in roasting; and, in some cases, soup may be made of the liquor. It is a general direction for boiling, that all meat, poultry excepted, should be put into cold water, and not boiled too fast. In every case, let care be taken to remove the scum from the top of the water, just before it boils; this keeps both the meat and the water clean, and agreeable in appearance. As the water decreases from evaporation, replenish with hot or boiling water, so as to keep the meat always covered. It is usual to allow a quarter of an hour for every pound of the meat in boiling, reckoning from the time the water begins to boil; but this is a rule which will of course be departed from according as the meat is required to be over or under done. In some cases, slow simmering is the most advantageous mode of dressing, and it is always better to boil slowly than quickly. Rapid boiling hardens the meat. Perfectly fresh meat requires longer boiling than that which is tender or ripe. Good meat swells in boiling, whatever may be the loss of weight.

When meat of any kind is done, and has to be lifted from the pot, take care not to put a fork into any part where there are juices; if this be not attended to, a portion of the juices will escape, and the marks of the fork will produce an unsightly appearance in the meat. All parts of mutton and lamb may be roasted, but it is only the leg, neck, and head, that are boiled.

To boil a salted Round of Beef.—If large, cut out the bone, roll it up firmly, and bind it with a tape; then put it into the pot, and keep the lid close. Boil it slowly and equally, allowing, as above mentioned, a quarter of an hour for each pound of the beef.

The appropriate garnishing for this and other pieces of boiled salt beef, is carrot and small greens; some add turnips. Put a little of the liquor in which it has been boiled in the dish.

To boil a Leg of Mutton.—A leg of mutton should be kept four or five days before boiling. Before putting it into the pot, bend round the shank, cutting the tendon at the joint if necessary, so as to shorten the leg. Two hours of slow equal boiling will be sufficient for a good-sized leg of mutton. Some persons, to make the leg look white and tasteful, wrap it tightly in a cloth in boiling; but this spoils the liquor for broth. It is not safe to boil vegetables with a leg of mutton, as they are apt to flavour the meat. Dish the leg with a little of the liquor, placing the lower side uppermost, conveniently for carving. A good leg of mutton will soon yield sufficient gravy.

The sauce used is finely chopped capers in melted butter. Turnips mashed or whole form the appropriate vegetable to be eaten with this dish.

To boil a Leg of Lamb.—A leg of lamb, when well boiled, is a delicate and excellent dish. It requires about an hour and a half. When whiteness is desirable, it is wrapt in cloth, the same as mutton. When dishd, garnish with the loin cut into chops, and fried, to lay round it. The sauce used is plain melted butter, or parsley and butter.

To boil Veal.—Veal is seldom boiled, being too insipid by that mode of dressing. The only part boiled is the knuckle, which requires much boiling, in order to soften the sinews. It is eaten with boiled ham or bacon. The sauce used is parsley and butter. The liquor from boiled veal is the best of any for making soup.

To boil a Turkey.—Boiled turkey is one of the most delicate and excellent dishes which can be brought to table, and should be dressed with as much care as possible. Clean the turkey from all feathers, and singe the hair with burning paper, being careful not to blacken the skin. Clean it well inside by drawing and wiping. Cut off the legs at the first joints, and draw out the sinews; then pull down the skin and push the legs inside. Cut off the head close to the body, leaving the skin long, and draw out the craw. Make a stuffing of chopped suet, crumbs of bread, chopped parsley, pepper, salt, and a little nutmeg, which wet with an egg and milk. Put this stuffing into the breast, leaving room for the stuffing to swell; after which draw the skin of the breast over the opening, and sew it neatly across the back; by which means, when the turkey is brought to table with its breast uppermost, no sewing will be seen. Place the liver in one wing, and the gizzard in the other, turning the wing on the back, and fixing the wings to the sides with a skewer. The turkey being now ready for the pot, put it into a cloth and boil it for a length of time according to the size and age. A small young turkey will not require more than an hour and a half; an old and larger one perhaps two and a half or three hours. Let the water be warm in putting in, and of sufficient quantity to keep the turkey always covered.

When done, and placed in a hot dish, pour a little sauce over the breast, and put the remainder in a sauce tureen. The sauce used is various, as parsley and butter, celery, or oyster sauce. One of the most delicate and agreeable sauces, is that which is made of melted butter, boiled macaroni, and milk.

To boil a Fowl.—A fowl is to be prepared for boiling

in the same manner as a turkey, except that no stuffing is used. It may be boiled with or without a cloth. Small fowls will require from half an hour to three quarters of an hour; large fowls will require from an hour to an hour and a half. Sauce, parsley and butter.

To boil Rabbits whole.—Wash them well in warm water. They may be either stuffed or not stuffed, according to taste. When stuffing is required, make it of crumbs of bread, suet, parsley, and onions—all chopped—and pepper and salt; moisten with milk and egg. Sew this neatly into the belly. Truss in the same manner as roast hare, and boil slowly for an hour. The sauce to be made of boiled onions, milk, melted butter, and flour, with pepper and salt, which pour over the rabbits when dished. This is called *rabbits smothered in onions*.

When two rabbits are dished together, lay the head of one in a contrary direction to that of the other.

To boil a Ham.—If the ham has been cured long, it may require soaking in cold water to soften it, from twelve to twenty-four hours before dressing. Put it in a large boiling vessel, with plenty of cold water, and let it simmer slowly from two to four hours, according to the size. Skim it frequently, to remove the grease which is constantly rising to the top. When done, skin it, and strew bread raspings over the upper side; then place it before the fire to dry and brown. Garnish with greens or cabbage.

To boil Leg of Pork.—Pork requires to be particularly well boiled. Place it in the pot with the skin side uppermost, with a plate below it, for pork is very apt to stick to the bottom of the pot. Peas pudding is generally served separately with this dish.

To boil a Tongue.—If hard, soak the tongue in water all night before using. Boil it from two hours and a half to three hours. Skin it before dishing. Garnish with greens or cabbage.

To boil Tripe.—When tripe is purchased from the butcher in a raw state, it requires to be boiled a very long time, to be thoroughly soft and tender. The length of time will depend on the age of the animal from which it has been taken. Sometimes, for young tripe six or seven hours will be sufficient, while old tripe will perhaps take ten or twelve. In all cases, boil, or rather simmer it very slowly, for quick boiling hardens it. It should be cut into moderately sized pieces for helping at table. When to be served plain, carry to table in a hash dish, in some of the water with which it has been boiled, with boiled onions in it. A tasteful way of serving, is to take it from its liquor after boiling, and stew it for about ten minutes in a saucepan with milk, which thicken with a little arrowroot, or flour and butter, and season with pepper and salt. This makes a delicious and cheap dish.

To boil Cow-heel.—Cow-heel should be boiled for five or six hours, or till the bones will slip out. Serve with a sauce of chopped parsley and butter.

STEWES, HASHES, AND MADE DISHES.

Stewing is the preparing of meat by slow simmering or boiling, and by which all the liquor is to be used along with the meat at table. This is a much more savoury mode of cookery than boiling, because the substance of the meat is partly in the liquor, and is seasoned to have a high relish or flavour. Generally, much more can be made of meat by stewing, than by roasting, broiling, or frying, because nothing is lost in the process of dressing. It also possesses the decided advantage of being a way by which meat may be dressed for a person whose time of dining is uncertain. A stewed steak, for instance, will keep warm and in good condition for an hour, but a broiled or fried steak cannot keep a minute after dressing.

To stew a piece of Beef, or make Beef Bouilli.—Take a piece of beef—the brisket or rump, or any other piece that will become tender. Put a little butter in the bottom of the stew-pan, and then putting in the meat, partially fry or brown it all over. Then take it out, and lay two or three skewers in the bottom of the pan;

after which replace the meat, which will be prevented from sticking to the pan by means of the skewers. Next, put in as much water as will half cover the meat. Stew it slowly, with the pan closely covered, till done, with a few onions, if required. Two hours are considered enough for a piece of six or eight pounds. When ready, take out the meat, and thicken the gravy with a little butter and flour. Cut down into handsome shapes a boiled carrot and turnip, and add them to the liquor; season with pepper, salt, and a little ketchup. Boil all together for a few minutes, and serve in a hash dish.

To stew a Shoulder of Mutton.—Take a shoulder of mutton, and cut out the blade bone without injuring the form of the meat. Make a stuffing of crumbs of bread, chopped suet and parsley, a little green or dried sweet herbs, chopped onion, and pepper and salt, moistened with egg and milk. Lay this stuffing in the place from which the bone was cut out; then roll it up, and skewer or bind it firmly with tape. Rub the bottom of a stew-pan with suet or butter, and brown the mutton. When sufficiently brown, lay two skewers in the bottom of the pan; add a little stock or boiling water, and let it stew for an hour and a half; the gravy drawn from itself will be sufficiently rich for sauce, seasoned with pepper and salt. Skim it before serving, to remove the fat.

To stew Steaks and Chops.—Cut the beef in slices rather thinner than for broiling or frying. Put them in a stew-pan, with water sufficient to make gravy. Add grated carrot, turnip cut in small squares, and pepper and salt. Stew for an hour, or till tender. Skim if necessary. When done, thicken the gravy with a little arrowroot or flour, and flavour with ketchup. Some persons add a little macaroni or vermicelli, which requires from ten to twenty minutes' boiling along with the stew.

Mutton chops are stewed in the same manner, but require to be trimmed of the superfluous fat, and more carefully skimmed. This is called *haricot of mutton* when the chops have been previously browned. The same directions will serve for stewing slices or pieces of any other kind of meat.

To stew Veal.—The best parts of veal for stewing are the fillet, the breast, and the shoulder. The shoulder must be stuffed when the knuckle is cut out, which must be done neatly, without disfiguring the meat; the stuffing should consist of bread-crumbs, minced suet, chopped parsley, grated lemon-peel, white pepper and salt, moistened with egg and milk; fill the shoulder, and sew it up. Rub the bottom of a large stew-pan with butter, lay in the veal, and brown it on both sides. When sufficiently brown, put in a pint of cold water, and stew it slowly for two hours, or, if large, two hours and a half. Before it is to be dished, draw off the gravy, and if not thick enough, brown a little butter, and dust in a little flour; put it amongst the gravy, and season with Cayenne, salt, and the squeeze of a lemon (a glass of sherry will be an improvement); skim the sauce, and pour it over the meat before dishing.

To stew Kidneys.—Cut the kidneys into slices; wash them, and dry them with a clean cloth; dust them with flour, and fry them with butter until they are brown. Pour some hot water or beef gravy into the pan, a few minced onions, pepper and salt, according to taste; let them stew slowly for an hour, and add a spoonful or two of mushroom ketchup before dishing.

To stew Pigeons.—Pick and wash the pigeons well, trussing them as fowls for boiling. Put a piece of butter and some pepper inside; dust them with flour, and brown them in a covered stew-pan with a good piece of butter; put in a little flour; add some gravy or hot water. Season them highly, and let them stew slowly for twenty minutes or half an hour. Before dishing, add half a glass of port wine, if the flavour be approved.

To stew Rabbits.—Wash the rabbits well; cut them in pieces, and put them in to scald for a few minutes. Melt a piece of butter, in which fry or brown the rab-

bits for a short time. When slightly browned, dust in some flour; then add as much gravy or hot water as will make sufficient sauce. Put in onions, ketchup, pepper and salt, according to taste. Stew for an hour slowly. When required, flavour the gravy with a small quantity of curry powder.

To make Irish Stew.—Take a piece of loin or back-ribs of mutton, and cut it into chops. Put it in a stew-pan with pared raw potatoes, sliced onions, pepper, salt, and a little water. Put this on to stew slowly for an hour, covered very close; and shake it occasionally, to prevent it from sticking to the bottom.

To make English Stew.—English stew is the name given to the following excellent preparation of cold meat. Cut the meat in slices; pepper, salt, and flour them, and lay them in a dish. Take a few pickles of any kind, or a small quantity of pickled cabbage, and sprinkle them over the meat. Then take a tea-cup half full of water; add to it a small quantity of the vinegar belonging to the pickles, a small quantity of ketchup, if approved of, and any gravy that may be set by for use. Stir all together, and pour it over the meat. Set the meat before the fire with a tin behind it, or put it in a dispatch, or in the oven of the kitchen range, as may be most convenient, for about half an hour before dinner-time. This is a cheap and simple way of dressing cold meat, which is well deserving of attention.

To hash Cold Beef or Mutton.—Cold roast beef, or cold roast or boiled mutton, may be dressed as a hash in the following manner. Cut the meat from the bones into small pieces, and lay them aside. Then put the bones in a stew-pan, with a little water and sliced onion. After stewing for a short time, take out the bones and put in the meat. When the meat is perfectly hot, thicken with a little flour and butter, and season with pepper and salt, and a little ketchup. Dish the hash, and stick small triangular pieces of dry toasted bread round the inner edge of the dish.

To dress Cold Boiled Beef, or make Bubble and Squeak.—Cut the beef in slices of about the third of an inch in thickness. Fry the slices till lightly browned, and heated through. Then take them from the pan, and place them on a warm plate before the fire, to keep hot. Fry some cabbage which has been previously boiled and chopped; stir this about a short time in the pan, and season with pepper and salt. Spread the cabbage in a dish, and place the slices of meat upon it; or heap the cabbage in the dish, and place the meat around it.

To mince Cold Veal.—Cut the veal from the bones, and mince it in small square bits, and lay them aside. Then put the bones in a stew-pan with a little warm water, to make a gravy. After stewing for a short time, take out the bones and put in the bits of veal, with a small piece of lemon-peel, chopped very fine. When perfectly heated, thicken with a little flour and butter, and season with pepper and salt, and a little lemon-juice. Dish with small pieces of toasted bread, as in hashed mutton.

To dress a Lamb's Head and Pluck.—Lambs' heads are procured skinned. Take the head with the neck attached; split up the forehead, and take out the brains, which lay aside. Wash the head carefully, cleaning out the slime from the nose, by rubbing it with salt, and take out the eyes. The head being thus cleaned, put it on to boil, along with the heart, and the lungs or lights. Let the whole boil for an hour and a quarter; then take them out, and dry the head and neck with a cloth. Rub it over with an egg well beaten; strew crumbs of bread, pepper and salt, over it; also stick small pieces of butter over it, and lay it in a dish before a clear fire, to be browned lightly. Mince the lungs and heart, and part of the liver, with some onion, parsley, pepper, salt, a little flour, grated nutmeg, and a tablespoonful of ketchup; mix all together, and add some of the liquor in which the head was boiled to form a gravy; let it simmer by the side of the fire for half an hour. Take the brains and beat them well with two eggs, two tablespoonfuls of flour, and a sprig of fine chopped parsley, also a little pepper and salt,

and two or three tablespoonfuls of milk—the whole forming a batter. Have a frying-pan with a little lard or dripping, and fry the batter in small round cakes, which turn and brown lightly on both sides. Cut the remainder of the liver in slices, and dust it with flour, and fry it. Now, lay the head upon a dish; place the hash round it, and lay a slice of liver and a brain cake alternately on the hash all round.

This forms a handsome and a savoury dish, but requires great attention on the part of the cook, to have all the various parts hot and equally ready at the time of dishing.

To make Potted-Head.—This is a dish to be eaten cold as a jelly. Take the half of a bullock's head and clean it; soak it in warm water, with a cow-heel, for two or three hours. Then boil it with the heel till tender. When done, cut them in small pieces, and lay them aside; after which, strain the liquor in which they have been boiled, and let it stand till it is cold, so that the fat may be easily skimmed. Put the whole into a saucepan, and boil for half an hour, and season with pepper and salt according to taste. Pour it into basins, or tin or earthenware shapes, which stand in a cool place. When quite cold, it forms a jelly, and is ready for being turned out on a dish for use. If it do not come out easily, dip the basin or shape in hot water, and the heat will immediately loosen it. Garnish with sprigs of fresh parsley.

SOUPS AND BROTHS.

Soups are the substance of meat infused in water by boiling, and are of many different kinds, but may be divided into two classes, namely *brown* and *white*. The basis of brown soups is always beef, while the basis of white soups is generally veal. Broths are preparations of soup, but more simple in their nature, and usually containing some kind of vegetables or matter for thickening, as rice, barley, &c. Soups of every description should be made of sound fresh meat and soft water. It is a general rule to allow a quart of water for every pound of meat; also to boil quickly at first, to make the scum rise, which is assisted by adding a little salt; and after skimming, to simmer gently.

To make Brown or Gravy Soup.—Take a shin or piece of the rump of beef, and break it in several places. Cut the beef from the bones; take out part of the marrow, and lay it on the bottom of the pot. If there be no marrow, use butter. Then lay in the meat and bones to brown. Turn the whole, when browned, on one side, and take care that it does not burn. When it is thoroughly browned, add a pint of cold water to draw the juice from the meat, also a little salt; and in a quarter of an hour after, fill in the quantity of cold water which may be requisite. Now add the vegetables, as for instance, two carrots, a turnip, and three or four onions, all sliced; also a stalk of celery, some sweet herbs, with some whole black and Jamaica pepper. Let the soup boil slowly for from four to five hours, after which take it off, and let it stand a little to settle. Then skim off the fat, and put it through a hair sieve to clear it. The soup, if cleared, may now be either served or set aside for after use. It should have a clear bright look, with a brownish tinge. Frequently, it is made the day before using, in order that it may be effectually skimmed of fat. In such a case, it is heated again before serving. On some occasions, it is served with a separate dish of toasted bread cut in small squares.

The meat which has made the soup is supposed to be divested of nearly all its nourishing qualities; but where thriftiness is consulted, it may form an agreeable stew, with vegetables, a little ketchup, and pepper and salt.

Brown soup, made as above directed, forms what is called *stock*, that is, a foundation for every other soup of the brown kind, also a gravy for stews where richness is required. It likewise forms any kind of vegetable soup, by merely adding to it, when just finished boiling and clearing, the particular vegetable which may be required. Thus are formed *carrot soup*, the

carrots being cut into small stripes or straws; *leek soup*, by adding leeks cut into short pieces, and boiling an hour; *vermicelli soup*, by adding boiled vermicelli; and so on with other vegetables.

Kidney Soup.—Make a stock, or gravy soup, as above directed. Cut two beef kidneys in slices; wash them well, and stew them in water or soup for an hour. Take out the kidneys and strain the soup. Then return the kidneys to the soup so strained, and add as much stock or gravy soup as is required. Let the whole boil for a few minutes, and serve in a tureen.

Pigeon Soup.—Make a stock, or gravy soup, as above directed. Add to this the livers and gizzards of your pigeons, and boil for half an hour. Then truss the birds as for boiling, and season them inside with pepper and salt; dust them over with flour, and brown them with a little butter in a frying-pan. Mix a little butter and flour, and stir it into the soup to thicken it. Strain the soup, and put the pigeons into it. Let the soup with the pigeons boil very gently for half an hour, skimming when required, and serve in a tureen.

Ox-tail Soup.—Make a quantity of brown soup, as previously directed. Take two or three tails, and separate them at the joints into pieces. Put the whole in the soup, and boil till the meat is tender, but not till it comes from the bones. Add a little ketchup, and serve with the pieces of tail in the soup.

Hare Soup.—Take a fresh hare, and, when skinned, wipe it well with a cloth. Cut it open, and take out the entrails, taking great care not to lose any of the blood. Then cut the body into separate pieces, and put them in a pot with two or three quarts of water, along with any blood that may have run out. Put into the pot, also, two or three pounds of beef cut into pieces, likewise a sliced carrot, turnip, and onion, a few sprigs of thyme, a few Jamaica pepper-corns, and four tablespoonfuls of flour mixed with cold water. Keep stirring till it boil, and let it boil for an hour and a half. When this is done, take the best pieces of the hare, which are the back and upper joints of the hind legs. Lay these aside. Let the soup boil for other two hours. Then take out the remainder of the meat, and cut it off the bones, and pound it in a mortar, or otherwise mash it well. Put the meat thus pounded back into the soup, and strain the whole through a hair sieve. Put the soup so purified into the pot, along with the best pieces of the hare which were laid aside, also two tablespoonfuls of ketchup. Boil this for half an hour: then add pepper and salt, and serve with the pieces of hare in the tureen.

Jugged Hare.—After having skinned, drawn, and washed the hare, cut it into pieces, and put the pieces into a jar with an onion, a bunch of sweet herbs, and a little water. Cover the top of the jar so close that very little of the steam can escape from it; the cover may be tied down to the jar. Place it in a saucepan of water, the water not to cover the top of the jar. Keep the water constantly boiling. Boil between three and four hours. When done, skim off any fat, thicken the sauce with flour and butter, season with salt and pepper, and serve all together in a hash dish.

Mock-Turtle Soup.—This is made with a calf's head. It is best to get the head ready scraped and cleaned from the butcher, but with the skin on. If it be got in an uncleaned state, wash it, and put it into a pot with cold water, and boil it for a short time till the hair is loosened. Then scrape off the hair, split the head, clean it thoroughly, and take out the brains. The head is now supposed to be clean, and ready for making the soup. Put it into a pot with considerably more water than will cover it. Skim it frequently as it warms, and let it boil gently for an hour. Take out the head, and when it has cooled, cut the meat off into handsome pieces, of about an inch square. Scrape and cut the tongue in the same manner. Lay all these pieces aside. Then put into the water in which the head was boiled, about three or four pounds of hock of beef and a knuckle of veal, with the bones broken. Add to this four or five onions, a carrot and turnip sliced, a small

bunch of sweet herbs, and some black and Jamaica pepper, whole. Add also the brains, after you have boiled them separately in a cloth, and pounded them. With all these additions let the soup boil slowly for four or five hours, after which strain it, and when cool, take off the fat. Take a quarter of a pound of fresh butter, and melt it in a stew-pan; when melted, put in two handfuls of flour and let it brown, stirring it all the time; add a little of the soup, a sprig or two of sweet basil, and a few heads of parsley. Boil this for a quarter of an hour; strain it through a sieve; then put this, the pieces of meat, and the soup, all together, and boil it for an hour. Add two tablespoonfuls of ketchup, the juice of a lemon, Cayenne pepper, and salt, to taste. It is usual to put in at the same time four glasses of sherry wine. When dished in a tureen, put in two dozen of egg-balls.

Egg-Balls for mock-turtle soup are made as follows. Boil four or five eggs till they are quite hard. Take out the yolks, and beat them in a mortar, with salt and Cayenne pepper. Make this into a paste with the white of one or two raw eggs. Roll the paste into balls the size of small marbles. Roll them in a little flour, and either fry them in butter or brown them before the fire, being careful to keep them whole and separate. They are now ready for being put into the soup.

Peas Soup.—This is an excellent soup, if well made, and is one of the cheapest dishes that can be put on the table, for it may be formed of cold meat or marrow-bone, or, what is cheaper still, merely water, or the liquor in which any piece of mutton, lamb, or veal, has been boiled. We give the following two recipes for making it:—

Peas Soup with meat or bones.—Take a good marrow-bone, or the bones of cold roast beef; a slice or shank of ham may be added, if the flavour be liked. Break the bones, and put them in the pot with four quarts of cold water. According to the thickness and quantity required, take two or three pounds of the best split peas, and put them among the cold water and bones; add to this two carrots, two turnips, half a dozen small onions, a stalk of celery cut in pieces, a bunch of thyme, and some whole black and Jamaica pepper. Let all this boil for two hours, stirring frequently, as the soup is very apt to burn. When the peas are quite soft and broken down, take the soup off, and put it through a sieve, into another pot; rub it well through until the pulp be mixed with the soup. Add salt melted amongst a little water, and boil the soup again for a few minutes.

When to be served, cut a slice of toasted bread into small square pieces, and put in the tureen with the soup.

Peas Soup without meat or bones.—Put two pounds or pints of peas in five quarts of water. Boil for four hours; then add three or four large onions, two heads of celery, a carrot and a turnip, all cut up; and season with salt, to taste. Boil for two hours longer. If the soup become too thick, add a little water. The peas may be boiled the evening before being used, and the longer they boil, the smoother and more mellow the soup will be; but do not put in the vegetables until the day the soup is to be used. By this plan the soup does not require straining.

Mutton Broth.—This is a broth of a mild nature, being intended chiefly for invalids. Take a scrag or thick end of a loin of mutton, and put it into a pot with cold water; the proportion being a quart of water to a pound of meat, which will allow for loss in boiling. Turnip and onion may be added when not considered injurious. Let this boil slowly for three hours, and skim off all the fat before serving. The meat is supposed to be useless.

Beef Tea.—Take a pound of lean beef, which cut in pieces, and put into a saucepan with a quart of cold water. Place it on a slow fire, and skim it carefully as it heats. Let it simmer gently for about an hour, and before serving, strain it through a hair sieve. Season with a little salt.

Another method.—Take a pound of good lean juicy beef, and cut it into very thin slices, which place in a

basin. Then pour a pint and a half of boiling water on the meat, moving it frequently with a fork or spoon, to cause the water to act upon all sides of the meat, and so extract its juices. Let it remain in the water about a quarter of an hour, after which pour the water into a saucepan, and boil it for about ten minutes. Skim, and season with salt. This is the most delicate way of making beef tea.

SCOTCH DISHES.

Sheep's Haggis.—There are different ways of making a haggis, as far as the exact composition of the materials is concerned. Some put minced tripe in it, others put no tripe. The following is the more common, and, we believe, the best manner of making it: Procure the large stomach bag of a sheep, also one of the smaller bags called the king's hood, together with the pluck, which is the lights, the liver, and the heart. The bags must be well washed first in cold water, then plunged in boiling water, and scraped. Great care must be taken of the large bag; let it lie and soak in cold water, with a little salt, all night. Wash also the pluck. You will now boil the small bag along with the pluck; in boiling, leave the windpipe attached, and let the end of it hang over the edge of the pot, so that impurities may pass freely out. Boil for an hour and a half, and take the whole from the pot. When cold, cut away the windpipe, and any bits of skin or gristle that seem improper. Grate the quarter of the liver (not using the remainder for the haggis), and mince the heart, lights, and small bag very small, along with half a pound of beef suet. Mix all this mince with two small tea-cupfuls of oatmeal, previously dried before the fire, black and Jamaica pepper, and salt; also add half a pint of the liquor in which the pluck was boiled, or beef gravy. Stir all together into a consistency. Then take the large bag, which has been thoroughly cleansed, and put the mince into it. Fill it only a little more than half full, in order to leave room for the meal and meat to expand. If crammed too full, it will burst in boiling. Sew up the bag with a needle and thread. The haggis is now complete. Put it in a pot with boiling water, and prick it occasionally with a large needle, as it swells, to allow the air to escape. If the bag appears thin, tie a cloth outside the skin. There should be a plate placed beneath it, to prevent its sticking to the bottom of the pot. Boil it for three hours. It is served on a dish without garnish, and requires no gravy, as it is sufficiently rich in itself. This is a genuine Scotch haggis.

Lamb's Haggis.—This is a much more delicate dish, and less frequently made than a sheep's haggis. Procure the large bag, pluck, and fry of a lamb. The fry is composed of the small bowels, sweetbreads, and kernels. Prepare the bag, as in a sheep's haggis. Clean thoroughly the small bowels and other parts; parboil them, and chop them finely along with a quarter of a pound of suet. Mix with dried oatmeal, salt, and pepper, and sew the mixture in the bag. Boil it, and attend to it in the same manner as a sheep's haggis.

Broth or "Kail."—Broth is made of beef or mutton, but mutton is preferable, and is generally employed. The best broth is made as follows:—Put into a pot three quarts of cold water, along with a cupful of pearl barley, and let it boil. As soon as it boils, put in two pounds of the best part of the neck or back ribs of mutton. Allow it to boil gently for an hour, skimming occasionally, and watching to prevent boiling over. Then add one carrot grated, two small turnips cut in squares, a few small onions shred; also two or three pieces of carrot and turnip uncut. Instead of part of these vegetables, according to taste put in the half of a small cabbage chopped in moderately sized pieces, or if cabbage cannot be procured, a similar quantity of greens. Leeks are also used instead of onions. Boil the whole for an hour longer, adding if necessary a small quantity of hot water to compensate the loss in boiling. The broth is now supposed to be done. Season with salt only, and serve in a tureen.

The meat, which is not expected to be over-boiled, is served in a separate dish, garnished with the uncut pieces of turnip and carrot. By this preparation, both the broth and meat are used, so that a small quantity of meat produces food for a large number.

Hotch-Potch.—This is a dish only to be obtained in perfection in summer, when green peas are in season. Put on two quarts of water, and when it boils, put in three pounds of the back ribs of mutton or lamb, paring off the fat if there be too much. Put in with the meat two or three carrots cut into squares, and two grated, also three or four sweet young turnips in squares, a cauliflower and a lettuce cut down, a few young onions shred, a little parsley, and about a pint of sweet young peas. Boil this for an hour and a half, then take out the meat and cut it in chops, laying it aside. Add another pint of young peas, seasoning with pepper and salt; and when these peas are done, put in the chops. In a few minutes afterwards, serve up the whole in a tureen.

Sheep's Head.—Procure as good a sheep's head as possible. The first thing done is to singe it with a hot iron, so as to free it completely from every particle of wool. This process is always performed in Scotland by a blacksmith, or some other person who makes a business of singeing heads. The horns should have been previously sawed off by the butcher. When singed and ready for the cook, soak the head for some time in warm water, and then scrape it till it is perfectly clean, and as nearly white as possible. The head must now be split, and the brains removed. Take out the eyes, and scrape and clean out the nose; after which wash the head again, and let it lie in warm water for a short time. It is usual to procure the trotters along with the head, and to subject them to a similar treatment, as regards singeing, cleaning, and washing. The head and trotters being now ready for the pot, put them in with a sufficiency of water, and let them boil till the skin is soft and tender, which may be in three hours. When ready, serve with the trotters round the dish, and garnish with boiled carrot and turnip. Some persons serve with parsley and butter.

Mince'd Collops.—Take a pound of good juicy beef, and a proportionate quantity of suet. Mince the whole very fine, as if for sausages, taking away any bits of gristle or skin. Melt a piece of butter in a frying-pan, and then put in the collops. Stir them well, adding a little flour, a little hot water or gravy, and season with pepper and salt, and a little ketchup. Onion may be chopped and put in along with the meat, if required. Ten minutes will dress a pound, which will form a dish for four or five persons. Serve in a hash dish.

Potato Soup.—Take any bones of cold roast meat, or a marrow-bone, or, failing these, a piece of dripping, which put into a pot with cold water, according to the quantity required. Let it boil a short time; then put in a quantity of potatoes well peeled or scraped, which have been previously soaked in boiling water to extract any disagreeable flavour from them. Add also one or two onions cut in pieces, a little pepper and salt, and let all boil for half an hour.

SAUCES AND FLAVOURS.

Sauces are liquid preparations to be used in giving a flavour or relish to dishes, and are of various kinds. A number are formed of melted butter, with an infusion of some other ingredients; others are in the form of gravies drawn from fresh juicy meat; and a third kind are composed partly of water, and some preserves, condiments, or spices. There is little merit in making a good sauce when a person has good and proper materials to make it with. The chief merit consists in furnishing a fine flavour from inadequate materials; as, for instance, giving a rich flavour of meat to a mass of potatoes, or some other plain dish, when no meat has been employed. This can only be done by knowing the qualities of various vegetable products, and how these, by means of cookery, may be made to resemble the juices of animal food. The vegetable products of

which by far the most can be made by a skilful cook, are onions, mushrooms, and carrots. Onions and mushrooms, alone, furnish the most effectual substitutes for animal juices, and may be dressed so exquisitely as hardly to be distinguished from the gravy of beef.

Onion Flavour.—Onion flavour is made by stewing. Take several large onions, and remove the thin outer film from them. Put them in a saucepan with a little salt and flour, and a small piece of butter or dripping, to prevent their burning. Cover them quite close, and set by the fire to brown and stew gently. Two hours will dress them, and at the end of this time they will be quite soft, and, with the addition of a little water, they will yield a rich gravy. This may be used to fry potatoes with, or to flavour any other dish.

Mushroom Sauce.—Pick out the stems, and skin the mushrooms and the stems. Cut them in small pieces, and wash them. Then put them in a saucepan, with rather more water than will cover them. Let them stew gently for about half an hour, or till they are soft. They will now have yielded a fine rich sauce. Stir in a little flour and butter kneaded together, and season with pepper and salt. This preparation may be eaten with potatoes, the same as meat; it also forms an excellent sauce to many dishes.

Melted Butter.—This must be made of fresh butter. Cut down the butter into small pieces, and put them into a small saucepan with cold water, in the proportion of an ounce of butter to a tablespoonful of water. Throw in flour from a dredger with the one hand, while with the other you turn the saucepan rapidly round, so as to cause the flour to mix without lumping. A small quantity of flour is sufficient. You now for the first time take the saucepan to the fire, and continue turning or shaking it till the butter is thoroughly melted. When it boils, it is ready; it should then have the consistency of rich cream. If it should oil in making, it may be partially recovered by putting a little cold water into it, and pouring it several times into and out of a basin.

This sauce is the foundation of a number of other sauces, various additions being made to it for the sake of variety.

Onion Sauce.—Skin the onions, and boil them in plenty of water. When they are soft, take them from the water, and chop them very fine. Melt butter as above, and stir them in, seasoning with a little pepper and salt.

Egg Sauce.—Boil three or four eggs till they are quite hard. Peel and chop them down, and then stir them into melted butter. Season with a little pepper and salt.

Cauld Sauce for plum-pudding.—Melt butter, as above directed, and stir into it a glass of sherry, half a glass of brandy or rum, a little sugar, grated lemon-peel, and nutmeg. Do not let it boil after the spirits are added.

Lobster and Crab Sauce.—Melt the butter, as above directed. Pick out the meat of a boiled lobster or crab; chop it down very fine, and put it amongst the butter. Season with Cayenne pepper, and salt. If the lobster be procured raw, with berries or spawn on the outside, these should be taken off previous to boiling, and being mashed in a little cold water, may be added to the sauce after the lobster is put in. By boiling a little, the whole will become a bright red. This forms an improvement on common lobster sauce.

Bread Sauce.—Grate down crumbs of bread. Put it in a saucepan on the fire, with as much sweet milk as will allow it to be thick. Add a piece of sliced onion, and stir it till the bread is soaked and the sauce is quite smooth. Season with pepper and salt.

Mint Sauce.—Take the leaves of fresh green mint. Wash them, and after drying them, chop them very fine. Mix them with vinegar, and add a little sugar.

Beef Gravy.—A pound and a half of beef will make a pint of good gravy. Cut the beef in slices, or score it very deeply. Place it in a saucepan, with a bit of butter to prevent it from sticking, and a sliced onion.

Brown the meat gently, being careful not to let it burn. Cover it closely, and let it stand beside the fire for about half an hour, to allow the gravy to run from the meat. Then put in about a pint of hot water, and let it boil slowly for an hour and a half, with some whole pepper. Some persons put in to boil along with it, a piece of bread toasted hard and brown, which thickens the gravy a little and adds to its richness. Season with salt, and strain it through a hair sieve.

FISH.

Fish are dressed in a variety of ways, according to the taste of individuals. They are boiled, broiled, baked, stewed, and fried; but the most common modes of preparation are boiling and frying—boiling when required to be done in a plain way, and frying when a high relish or flavour is to be given to them. In all modes of preparing fish, much care is required to prevent them from being broken or disfigured.

To boil Salmon.—Clean out, scale, and rinse the fish in water. Then put it in a good roomy fish-kettle, with plenty of cold water, and a handful of salt. The usual time allowed for boiling salmon is twelve minutes to each pound, but this must in a great measure depend on the thickness of the fish. The way to ascertain when it is ready, is to raise one end from the water, and try if a knife will pass easily betwixt the fish and the bone. If it pass easily, it is dressed sufficiently. When done, lift it immediately from the water, and place the fish drainer across the kettle, to allow the water to drip from the fish. Serve on a dish with a fish plate and white napkin under it, the napkin being next it. Garnish with green parsley. Sauce—plain melted butter, parsley sauce, or lobster sauce in a tureen.

To broil Salmon, or Salmon Steaks.—Cut slices from the thick part of the fish, and having cleaned and scaled them, dry them, and dust them with flour. Broil them on a gridiron over a clear fire. When ready, rub them over with butter, and serve hot, with any of the sauces used for boiled salmon. Slices of hung or kippered salmon are broiled in the same manner.

To fry Trouts, or similar Fish.—Trouts of a moderate size are dressed whole, and frying is the best mode of preparation. Take the trouts, and clean out and scale them. Dust them with flour, and put them in a frying-pan with hot dripping or lard. Turn them, so as to brown them on both sides. Lift them out and serve them on a dish; they will be improved by laying a napkin under them to absorb the grease.

In the country parts of Scotland, trouts are rubbed with oatmeal instead of flour, and some reckon that this improves the flavour.

To boil Turbot.—Select a thick fish of a white creamy colour. After cleaning, but not cutting any part except in gutting it, lay it in salt and water, with the addition of a little vinegar, and let it soak a short time before boiling. Put it with the white side or belly upwards in a fish-kettle on the fire, with plenty of cold water, a handful of salt, and a cupful of vinegar. Let it heat slowly, and boil for half an hour after it has come to the boil. When done, serve with belly upwards, and garnish with any small fish fried, or with parsley and scraped horse-radish. Sauce—lobster, oyster, or plain butter.

To bake Turbot.—Cut a small turbot into slices, which clean and free from bones. Dip the slices in beat egg, and roll them in a mixture of crumbs of bread, minced parsley, pepper and salt. Place them in a dish well buttered all round, and bake them in an oven not very hot, or in a bachelor's or Dutch oven before the fire. They must be basted frequently with butter. When done, lay the pieces in a dish, and pour round them lobster or oyster sauce, highly seasoned with Cayenne pepper, salt, and ketchup. Instead of being baked, slices of turbot may be fried after being prepared as above, and served with plain butter sauce.

To boil Cod.—Wash and clean it, and boil as directed for turbot. Serve it on a napkin, garnished with parsley and scraped horse-radish. Sauce—oyster sauce.

To dress a Cod's Head and Shoulders.—Take a cod's head and shoulders in one piece, which clean, and let lie among salt all night. When you are going to dress it, skin it, and bind it with tape to keep it firm. Put it in a fish-kettle, back upwards, with plenty of cold water, a handful of salt, and a little vinegar. Let it heat slowly, and boil for about half an hour. Then let it lie on the drainer across the top of the kettle, for the water to drip from it. After this, place it, back upwards, on the dish in which it is to be carried to table, cutting and drawing away the tapes very carefully. Brush it over with beat egg, strew crumbs of bread, pepper, and salt, over it, and stick pieces of butter thickly over the top. Set it before a clear fire to brown. A rich oyster sauce, made with beef gravy instead of water, and highly seasoned with Cayenne pepper, salt, and ketchup, is poured in the dish around the fish. Do not pour any on the top of the fish.

To dress a Middle Cut of Cod.—Clean the piece of cod, and make a stuffing of bread crumbs, parsley and onions chopped small, pepper and salt, a bit of butter, moistened with egg. Put this stuffing into the open part of the fish, and fix it in with skewers. Then rub the fish over with beat egg, and strew crumbs of bread, pepper and salt, over it. Stick also some bits of butter on it. Set it in a bachelor's or Dutch oven before the fire to bake. Serve with melted butter or oyster sauce.

To boil Haddocks.—This is the simplest of all operations. Select haddocks of a middle size. Clean them well, and wash them, and boil with a little salt in the water. Twenty minutes or half an hour's boiling will be sufficient. Serve with oyster sauce.

To dress Haddocks.—This is a most delicious dish when well prepared. Take pretty large haddocks, which clean and wash well. They will be firmer and better if they lie for a night in salt. When to be dressed, wash them and dry them. Cut off the head, tail, and fins; then skin them, being careful not to tear the flesh. Cut the flesh neatly from the bone, and divide each side into two pieces. Dust them with flour, dip them into beat egg, and strew bread crumbs over them. Fry them in a frying-pan, with a sufficiency of hot dripping or lard to cover them. Be careful that the dripping is not hot enough to scorch the fish. The way to ascertain the proper degree of heat of the fat, is to dip a thin slice of bread into it, and when it makes the bread of a light brown tinge, put in the fish. If the fat be too hot, it will make the bread of a deep brown. Turn the pieces carefully, so as to brown both sides, and when done, lay them before the fire on a drainer for a few minutes. Serve in a dish, garnished with parsley. Sauce—oyster sauce, or plain melted butter.

The fat in which haddocks are fried will answer the same purpose again, if put through a hair sieve, and poured in a jar, and kept in a cool place.

To fry Skate, Soles, Flounders, Whitings, and Eels, and any other white fish.—Skate and soles are skinned and dressed in the same manner as haddocks, but soles are fried whole, not cut in pieces. Flounders are likewise fried in the same manner, whole, but do not require to be skinned. Eels must be skinned and cut in pieces.

To bake Haddocks.—Take two or three haddocks, gut and clean them, and lay them all night among salt. When to be used, skin them, and cut off the heads, tails, and fins. Make a stuffing of bread crumbs, chopped onions and parsley, and a little bit of butter. Sew this into the bellies of the fish. Rub them over with butter, strew bread crumbs over them, and bake them in an oven or before the fire.

Fish and Sauce.—Take two or three haddocks, gut and clean them, and lay them all night among salt. When to be used, skin them, cut off the heads, tails, and fins. Boil these trimmings for three quarters of an hour in a little water. Brown a little flour and butter in a stew-pan, and then strain the liquor and put it to the butter; add sliced onion, chopped parsley, salt, a little Cayenne pepper, and a spoonful of ketchup.

When all this has been boiled for a few minutes, cut the fish in several pieces, and let it boil gently till dressed.

To scallop Oysters.—Scald the oysters in their own liquor. Pick them out of the liquor, and lay them in a dish, or scallop shells, or tins, strewing crumbs of bread mixed with pepper and salt over each layer, and finishing with crumbs. Moisten the whole with a small quantity of the liquor in which the oysters were scalded, and stick pieces of butter thickly over the top. Place the dish before the fire to bake. From ten to twenty minutes will be required, according to the quantity.

DRESSING VEGETABLES.

All vegetables ought to be cooked fresh from being gathered, or as nearly so as possible. Excepting peas and spinach, each kind of vegetable should be boiled in a large quantity of water, to carry off any rankness of flavour. They should also be served as soon as dressed, and not permitted to lie a moment in the water after they are ready for dishing. All kinds of cabbage and greens are the better for being boiled with a little carbonate of soda in the water, which will preserve their green appearance. The carbonate of soda is a material resembling flour in appearance, and may be obtained from any druggist. Cauliflower and broccoli require great care in boiling, for the flower easily breaks, and their appearance is spoiled. The time for boiling vegetables depends so much on their age, freshness, and size, that no directions can be given on that point. The best way to ascertain when they are ready, is to pass a fork through the stem.

To boil Green Peas.—Peas should not be shelled till just before they are to be used. After shelling, put them into boiling water, just enough to cover them, with a little salt; and when they are not very young, put a little sugar in the water. They will require about twenty minutes to boil. When done, strain them through a cullinder, and put them into a vegetable dish with a few bits of butter; stir them gently till the butter is mixed with them.

To boil Carrots and Parsnips.—Carrots require to be scraped, and to boil till they are soft. The length of time for them boiling depends on their age and size. Small carrots are served whole, but large ones should be cut in four pieces lengthwise. Parsnips require to be scraped and prepared in the same manner.

To boil Turnips.—Old turnips require to be pared much deeper than young ones. When they are very small, peel off the skins, but do not pare them; and after boiling, serve them whole, with a little melted butter in the dish. Large turnips are cut in pieces before being put in the pot, and they are either served in these pieces, or mashed with a little butter, pepper, and salt.

To boil French Beans and Scarlet Runners.—Cut off the tops and tails, and strip the strings from the backs of the pods. Then cut the pods in pieces slantingly across, or split them from one end to the other, and then cut them across. Lay them in cold water for a few minutes; and after straining them, put them into boiling water with a little salt and carbonate of soda. Boil till they are soft; strain them with a cullinder, and serve them with melted butter in a separate dish. Scarlet runners are prepared in the same manner, but usually require to be split into three or four pieces.

Potatoes.—These useful vegetables, as every one knows, may be dressed in a variety of ways. When to be presented plain at table, they may be either boiled in water or steamed. Some potatoes are best when boiled, while steaming is more suitable for other kinds. There is therefore no exact rule upon the subject. In general, they are better when they are boiled, and when put into just enough of cold water to cover them. A little salt should be put into the water to impart a flavour, and they should boil very slowly. Fast boiling will break their skins before they are soft in the inside. In most instances, they are spoiled by over-quick boiling. When sufficiently done, pour the water from them, and set

them by the side of the fire with the lid off, to allow the steam to escape, or fold a napkin and place over them to absorb the moisture. Before serving, peel them, and place them in a dish with a napkin over them. Plain potatoes should never be sent to table without a napkin, for it keeps them warm, and, at the same time, allows the moisture to escape. When potatoes are to be mashed, they are pared either before or immediately after boiling, and mashed so as to be completely free from lumps. Some milk and butter, and a little salt, are stirred in before serving.

Salads.—Salad is a general name for certain vegetables prepared so as to be served and eaten raw. Salads are composed chiefly of lettuce, endive, radishes, green mustard, land and water cresses, celery, and young onions. All or any of them should be washed, and placed ornamentally in a salad bowl; the lettuce is generally cut in pieces lengthwise, and stuck round the dish; the celery, also divided, is placed in the centre; and the small salads, such as cresses and radishes, are placed between. This is the mode of serving a salad plain.

A dressed Salad.—When a dressed salad is to be served, the whole is cut in small pieces, and mixed in the bowl with a dressing. The dressing is made in the following manner:—For a moderate quantity of salad, boil one egg quite hard; when cold, take out the yolk and bruise it with the back of a spoon on a plate; then pour on it about a teaspoonful of cold water, and about a teaspoonful of salt. Rub all this together till the egg has become quite smooth like a thick paste. Add a teaspoonful of made mustard, and continue mixing. Next, add and mix a tablespoonful of salad oil or cold melted butter. After this, add and mix a tablespoonful or more of vinegar. The dressing is now made, and may be either mixed with the salad, or put into a glass vessel called an *incorporator*, which is sent to table along with the salad. The top of the salad may be ornamented with small bits of the white of the egg, and pieces of pickled beetroot.

PIES AND TARTS.

Pies are of two distinct kinds—meat pies and fruit pies or tarts. Both are composed partly of paste, and therefore a knowledge of making pastry is indispensable in the economical housewife and cook. For this operation, the hands should be washed very clean, and care taken to have the board for working upon smooth, clean, and dry. A marble slab is better than a board, but few can command this convenience, and a board is usually kept for the purpose. Should the board or table be any way rough, lay a sheet of stout white paper upon it. Before commencing to roll or knead the paste, dredge a little flour upon it. In all cases of making paste, the butter, whether fresh or salt, should be perfectly free of taint, or any rankness of flavour. It is very necessary to give this direction, for many persons seem to imagine that butter of any kind, however bad, is good enough for paste. Dripping, when well prepared and kept, or lard, will answer as a substitute for butter, and make the paste equally agreeable to the taste. At one time, raised pies—that is, pies covered all over with paste—were common, but these are now rarely seen of a large size for families. Pies are now made in earthenware dishes, and merely covered with paste. The way to make paste for raised and covered pies is as follows.

Paste for covering Meat Pies.—A good common paste for covering dishes or meat pies, and which paste is intended to be eaten, is made as follows: Three ounces of butter, and one pound of flour, will be sufficient for one dish. Rub the butter well amongst the flour, so as to incorporate them thoroughly. If the butter be fresh, add a little salt. Mix up the flour and butter with as much cold water as will make a thick paste. Knead it quickly on a board, and roll it out flat with a rolling pin. Turn the dish upside down upon the flattened paste, and cut or shape out the piece required for the cover. Roll out the parings, and cut them into

strips. Wet the edges of the dish, and place these strips neatly round on the edges, as a foundation for the cover. Then, after putting in the meat, lay the cover on the dish, pressing down the edges closely to keep all tight. If any paste remain, cut or stamp it in ornaments, such as leaves, and place these as a decoration on the cover.

On taking pies from the oven, and while quite hot, the crust may be glazed with white of egg and water beat together, or sugar and water, laid on with a brush.

Beef-Steak Pie.—Take some slices of tender beef mixed with fat; those from the rump are the best. Season them with pepper and salt, and roll each slice up in a small bundle, or lay them flat in the dish. Put in a little gravy or cold water, and a little flour for thickening. Cover as above directed, and bake in an oven for about an hour.

Veal Pie.—Take chops from the back ribs or loin, and take out the bones. Lay the chops flat in the dish, and strew over each layer a mixture of minced parsley, flour, pepper, and salt. Add a little gravy, which may be made from the bones. Cover as above directed, and bake for rather more than an hour, for veal requires to be well dressed.

Pigeon Pie.—Pick and clean the birds well. Cut off the heads, and truss them by turning the wings on the back, cutting off the feet, and drawing the skin of the belly over the legs. Put a bit of butter, and a little pepper and salt, inside each bird. Place a single layer of beef or veal in the bottom of the dish. Lay the birds on the meat, with breasts upwards, and with the gizzards and livers round them. Some add a few whole hard-boiled eggs. Add a little gravy or water. Cover as above directed, and bake for an hour.

Icing for Tarts.—After tarts are baked, they are sometimes iced on the top, to improve their appearance. The icing is done in the following manner:—Take the white of an egg, and beat it till it is a froth. Spread some of this with a brush or feather on the top or cover of the tart, and then dredge white sifted sugar upon it. Return the tart to the oven for about ten minutes.

Apple Pie.—Pare and take out the cores of the apples, cutting each apple into four or eight pieces, according to their size. Lay them neatly in a baking dish, seasoning with brown sugar, and any spice, such as pounded cloves and cinnamon, or grated lemon-peel. A little quince marmalade gives a fine flavour to the pie. Add a little water, and cover with puff paste, as above directed. Bake for an hour.

Gooseberry Pie.—Pick the heads and stems from unripe or hard gooseberries, and rub them with a towel to clean them. Fill the dish with them, and add a considerable quantity of brown sugar, with a very little water. Cover as above directed, and bake for upwards of an hour. Some persons stew the gooseberries in sugar before putting them in the dish, in which case they require less baking.

Rhubarb Pie.—Take stalks of fresh-pulled rhubarb. Cut off all the leaf, and strip off the skins. Cut the stalks into pieces of an inch long. Fill the dish, adding plenty of sugar. Cover as above directed, and bake for half an hour. Some persons stew the rhubarb before baking; the advantage of this is, that more can be put into the dish, for it shrinks considerably in dressing.

Cranberry, Raspberry, and other Tarts.—Cranberries, raspberries, and other small fruits, may be made into pies in the same manner as gooseberries. All require to be picked and wiped, and to have sufficient sugar to sweeten them. The dish should also be well filled, and raised higher in the middle than the edges, for the fruits diminish considerably in bulk in baking.

Mince Pie.—Mince pie is a composition of meat, fruit, various spices and seasonings, and also spirits. The following is a properly proportioned mixture:—Take and mince a pound of beef suet, and a pound of roast beef, or dressed fresh bullock's tongue; also a pound of apples pared and cored, minced separately from the suet and meat; a pound of currants washed and picked,

a pound of stoned and chopped raisins, an ounce of ground cinnamon, half an ounce of ground ginger, an ounce of orange and an ounce of lemon peel, and a little salt; half a pound of raw sugar, one nutmeg grated, two glasses of brandy and two of sherry. Mix all these ingredients together, and lay the bottom of your dish or small tin pans with paste; fill these with the mince, and then cover them with puff paste. Put in the oven, and bake for half an hour. If the whole of the mixture be not used, what remains over will keep for a long time, if placed in a close jar. Some persons do not put any meat in their mince pies.

Open Tarts.—These are tarts without covers, made in flat dishes. Cover the bottom of the dish with a common paste; then cut a strip of puff paste and lay round the edge of the dish. Fill in the centre with any jam or preserved fruit. Decorate the top of the jam with narrow bars of paste crossed all over, or stamped leaves. Bake for half an hour.

PUDDINGS AND DUMPLINGS.

Care should be taken in making puddings to have the suet and the eggs which are put into them perfectly fresh. If there be any doubt of the freshness of the eggs, break each individually in a tea-cup, for one bad egg will spoil all the eggs in the dish. The cloths used for puddings should be of tolerably fine linen. Let them be carefully washed after using, and laid aside in a dry state, ready for the next occasion. Before putting the pudding into the cloth, dip the cloth in boiling water, and after the water has run from it, spread it over a basin, and dredge it with flour. Every pudding should be boiled in plenty of water, so as to allow it room to move freely; and it must be kept constantly boiling. It is a general saying among cooks, that a pudding *cannot be too well boiled*, and it is certain that there is much more danger of boiling it too short than too long a time. When you take the pudding from the pot, plunge it for a few seconds into a jar of cold water. This will chill the outside, and allow the cloth to be taken away without injuring the surface. The best way to dish a pudding, is to place it with the cloth in a basin, then open the cloth, and lay the face of the dish upon the pudding; turn the whole upside down, lift off the basin, and remove the cloth.

Plum Pudding.—A plum pudding may be made either rich or plain, according to the quantity of fruit and spices put into it. The following is the direction for making what would be considered in England a *good Christmas pudding*:—Take a pound of good raisins and stone them; a pound of currants, which wash, pick, and dry; a pound of rich beef suet minced, and a pound of stale bread crumbs, and half a pound of flour. Mix the bread, flour, and suet in a pan. Beat six eggs in a basin, and add to them about half a pint of sweet milk. Pour this egg and milk into the pan with the suet and flour, and beat it well with a flat wooden spoon for some time. Then stir in the currants and raisins, mixing well as you proceed; mix in also a quarter of a pound of candied orange and lemon peel, cut in thin small pieces, an ounce of powdered cinnamon, half an ounce of powdered ginger, a nutmeg grated, and a little salt. Next add a glass of rum or brandy. The pudding is now made, and ready to be either baked or boiled, according to taste. If to be baked, butter your tin or basin, and put the pudding into it, and bake in an oven for an hour and a half, or nearly two hours. If to be boiled, pour it into a cloth; tie the cloth, allowing a little room to swell if made of bread, and boil for six hours. Serve with candle sauce.

Currant Pudding.—An excellent family pudding may be made of the following ingredients:—A pound of minced suet, a pound of bread crumbs or flour, three quarters of a pound of currants, washed and picked, a little powdered cinnamon and grated nutmeg, and a very little salt. Beat two eggs, and add as much milk to them as will wet the whole. Mix all together, tie in a cloth as previously directed, and boil for three hours. Serve with candle, or any simple sweet sauce.

Hard Dumpling.—This is the plainest of all puddings, and is sometimes served with boiled salt beef. It is also sometimes cut in slices and placed in the dripping pan below roasting meat, for about half an hour before the meat is dished. Take a quarter of a pound of suet minced very fine; mix it with a pound of flour; add a little salt, and wet it with water to the consistency of dough. Divide it into small dumplings, and put them into boiling water, and boil for an hour and a half, taking care that they do not stick to the bottom of the pot. No cloth is used.

Bread Pudding.—Boil as much milk as will be sufficient for the pudding you want. When it begins to boil or rise in the pan, pour it upon crumbled down stale bread in a basin. The quantity of bread should be as much as will thicken the milk to a stiff consistency. Cover it up for ten or fifteen minutes, to allow the bread to swell. Then beat or mash it up to make a fine pulp, stirring in a small piece of butter. Beat three or four eggs, a teaspoonful of ground cinnamon, a little grated lemon-peel, and sugar according to taste. Stir this among the pudding. A little brandy or rum may be added; also a few currants, if required. The pudding may be either boiled or baked. If to be boiled, put it in a well-buttered pudding shape or basin, with a buttered paper over it, and also a cloth over all: boil for an hour. If to be baked, put it into a buttered baking dish, and bake in an oven for half an hour.

Rice Pudding.—Take a pretty large cupful of rice, pick it, and wash it well in cold water. Boil it in water for about five minutes. Drain the water off, and put it on again with as much milk as you require. Let it boil till the rice is quite soft, stirring it frequently to prevent it from burning. When done, put it into a basin, and stir in a piece of butter, or some suet minced very fine. When cold, add to it four eggs beaten, with a little ground cinnamon, grated nutmeg and lemon, and sweeten with sugar. All is to be mixed well together. It may be either boiled or baked, as directed for bread pudding. The above composition may be enriched by using more eggs and less rice, also by adding currants, spirits, and candied orange and lemon peel.

Custard Pudding.—Take four eggs, and beat them well with two tablespoonfuls of flour and a little cold milk. Season this with sugar, ground cinnamon, grated lemon-peel, and pour on a pint of boiling milk, stirring all the time. It may be either baked or boiled. By using more eggs, the flour may be omitted.

Bread and Butter Pudding.—Cut several slices of bread rather thin; butter them on one side; put a layer of them in a pudding pan or dish, and a layer of currants above; then another layer of bread, and so on till the dish is full. Beat four eggs, with a little ground cinnamon and nutmeg, also some sugar. Add milk to this, till there is sufficient to fill up the dish. Then pour it over the bread, and allow it to stand for a time to soak. It will now be ready for either baking or boiling, as directed for bread puddings.

Tapioca Pudding.—*Sago Pudding.*—Take a quart of milk, and put in it six tablespoonfuls of tapioca. Place it on the fire till it boil; then sweeten to taste, and let it simmer for a quarter of an hour. Stir it frequently, and be careful that it does not burn. Then pour it into a basin, and stir into it a little fresh butter and three eggs well beaten; you may now pour it into a buttered pudding dish, and bake for about an hour; or, after adding another egg, boil it in a basin or mould for an hour and a half. Sago pudding may be made in the same manner.

Batter or Yorkshire Pudding.—Take a quart of sweet milk, and mix in it a large cupful of flour, making the mixture very smooth. Beat four eggs, and strain them into the batter. Add a little salt, and mix all well together. Butter your dish or tin, and pour the batter into it. Place the dish either before the fire under roasting meat, or under meat sent to the oven. The pudding, when done, easily shakes out of the dish into another dish to be carried to table. It should have a

nically browned appearance. When dressed before the fire, either turn the pudding, or place the dish a short time on the fire to brown the under side.

Peas Pudding.—Pick a quart of split peas, that is, remove all impurities, or discoloured peas, or shells. Tie them loosely in a cloth, leaving plenty of room for the peas to swell. Boil till they are soft, which may be in from two to three hours. Take the pudding from the water and put it into a basin. Open the cloth, and bruise or mash the peas well. Mix in a piece of butter, with pepper and salt. Then tie it up tightly, and put it into the pot again, and boil for about half an hour. When ready, turn it out of the cloth into a vegetable dish. If properly managed, it will turn out whole.

Fruit Puddings.—Fruit puddings consist of fruit enclosed in a paste, and boiled. They may be made of apples pared and cut in pieces, green unripe gooseberries, currants, raspberries, cherries, and other fruits. They are all made in the same manner. The best paste for them is made of beef suet chopped very fine, and flour, in the proportion of four ounces of suet to a pound of flour. Mix it into a dough with water and a little salt; then knead it and roll it out; place the fruit in it, gather up the edges, and tie it in a cloth, or place it in a basin, as directed for other puddings.

A Roll Pudding.—Make a paste of flour and dripping, or suet, as previously directed for plain paste. Roll it out flat, to about half an inch thick. Then spread gooseberry jam, or any other preserved fruit, over the paste, but not quite to the edges. After this, roll it up, and cause the outer edge to adhere. Next, roll it in a cloth, and tie the ends tightly. Boil it for an hour or an hour and a half, according to the size. When done, take the cloth off, cut the pudding in slices, and serve with any sweet sauce over it.

Meat Puddings.—Meat puddings are made in the same manner as fruit puddings, the only difference being, that pieces of beef, mutton, lamb, or veal, are placed inside of the paste instead of fruit. The meat should be seasoned with salt and pepper. One of the commonest of this kind of puddings is a beef-steak pudding. If it contain two pounds of meat, it will require about two hours and a half to boil, and if larger it will take a longer time.

LIGHT DISHES AND CONFECTIONS.

Under this head is included those various light and elegant dishes which are generally put upon the table in the last course, along with puddings and pies; also those preserves which are occasionally served at tea and supper parties. In making all articles of this description, very considerable care and cleanliness are required. The tin shapes or moulds for jellies should be kept particularly clean; if they are used with any particles of dirt inside, the jellies will in all likelihood not turn out neatly. It has been already mentioned, that the turning out may be facilitated by dipping the mould for an instant or two in hot water. It is a common belief that fruits, such as gooseberries and currants, cannot, without spoiling, be dressed for preserving, except in a brass, copper, or silver pan. This is an error. They may be dressed equally well in a tinned iron saucepan. Every kind of berries for preserving should be gathered in sunny weather, when the fruit is as free of moisture as possible.

In the following directions, no exact definition can be given of the quantity of small seasonings and spices to be used; that is left to the taste of the cook.

Custards.—Boil a quart of sweet milk, with stick cinnamon, the rind of a lemon, and a few laurel leaves or bitter almonds, and sugar. Beat the yolks of eight eggs along with the whites of four of them; add a little milk, and strain the egg into another dish. When the quart of milk boils, take it off the fire, and strain it; then stir the egg into it. Return the whole to the saucepan, and set it on the fire again, stirring constantly. Let it come to the boiling point; then take it off the fire, pour it into a large jug, and continue stirring it till it is nearly cold. It should now have the consistency of

thick cream, and is ready for being poured into custard glasses. When the glasses are filled, grate a little nutmeg over them.

Calf's-foot Jelly.—Take two calf's feet well cleaned; break them in several pieces, and put them in a saucepan with three quarts of cold water. Boil it slowly till it is reduced to about a quart and a half. Strain it, and let it stand till cold. Take off the fat carefully when cold. Put the jelly into a saucepan, keeping back the sediment; put in along with it the juice and the yellow rind of three lemons, two stalks of cinnamon, half a bottle of sherry wine, the whites of eight eggs well beaten, with the shells broken, and white sugar according to taste. Mix this all together, and put it on to boil for twenty minutes. Take it off, and let it settle with a cloth over it for a few minutes. Then pour it through a clean jelly-bag made of thick flannel. It will take some time to run; therefore hang the bag near the fire, cover it, and let the liquid run slowly from it into a jar. If not perfectly clear, run it through the bag again; but if as clear as is required, it is now ready, and may be poured into the shapes.

Plain calf's-foot jelly may be made with ale instead of wine, and vinegar instead of lemons.

Blamange.—Blamange, or Blanc-Mange—so called from its white appearance—is a jelly made of isinglass and milk. Take a quart of sweet milk, or cream; and put in it two ounces of the best isinglass. Put it in a saucepan, with the rind of a lemon, a blade of mace, and white sugar to taste. Let it boil a quarter of an hour. Take the skins off six bitter almonds and twenty-four sweet ones, and pound them to a paste with a little water. Mix this with the boiling milk, and strain it through a muslin sieve. Let it settle for a short time, and then pour it into the shape, keeping back the sediment. Turn out when cold, as already directed.

Arrowroot Blamange.—This is a jelly closely resembling the above, and is made with much less trouble. Take a quart of sweet milk, and put it all in a saucepan, excepting about half a pint. Sweeten it with white sugar. Mix about three tablespoonfuls of arrowroot with the half pint of milk, taking care to bray it all well down. When the milk on the fire boils, pour in the arrowroot, stirring quickly to prevent lumping or burning. It will become thick immediately. Let it boil for two or three minutes. Wet the shape with cold milk, and pour the arrowroot into it. Let it stand till cold, and turn out as already directed. Some persons flavour the milk in the pan with essence of lemon.

Moss Blamange.—There is a moss of a peculiar kind, found on the sea-shores of Iceland, Ireland, and other places, which is of a glutinous quality, like isinglass, and which, when boiled in milk, forms a fine smooth white jelly. The discovery of the properties of this plant is recent, and is yet not very generally known. We shall, therefore, be particular in our directions. The moss is called Iceland or Irish moss; it is sold by druggists, and when bought resembles dried sea-weed of a yellowish colour. Take one ounce (which will probably cost twopence), and pick from it all gritty or sandy particles. Soak it in cold water for about twelve hours. Take it from the water, place it in a cullinder, and drain it. Being drained, place it in a saucepan on the fire with a pint and a half of sweet milk. Let it boil for half an hour, and keep stirring it all the time, to prevent it from burning. During the boiling, sweeten it with sugar, and flavour it with cinnamon, or any other spice you please. At the end of the half-hour's boiling, the moss will be almost entirely dissolved, leaving nothing but a few thready fibres. You now strain it through a sieve, into a shape or mould. When cold, it will turn out easily, and have all the appearance of a firm blamange. This forms one of the cheapest blamanges that can be served to table; it is also agreeable to the palate, and very nutritious. In cases of a hurry in cooking, six hours' soaking of the moss will do, but this causes a waste.

Gooseberry Fool.—This is the simplest way of pre-

paring gooseberries, and very wholesome for children. Take a quart of full-grown unripe gooseberries. Pick them, and put them into a saucepan with a cupful of water. Cover them, and let them heat very slowly. When the gooseberries are soft and dressed, but not so much heated as to burst, strain the water from them, and put the gooseberries in a dish. Bruise them to a fine pulp, with sufficient sugar to sweeten them. Let them stand till cool, and then mix milk or cream with them. Serve in a hash dish, or large bowl.

MISCELLANEOUS PREPARATIONS.

To Boil Eggs.—The boiling of eggs is a very simple operation, but is frequently ill performed. The following is the best mode:—Put the egg into a pan of hot water, just off the fire. When you put in the egg, lift the pan from the fire and hold it in your hand for an instant or two. This will allow the air to escape from the shell, and so the egg will not be cracked in boiling. Set the pan on the fire again, and boil for three minutes or more, if the egg be quite fresh, or two minutes and a half, if the egg has been kept any time.

To Poach Eggs.—Take a shallow saucepan or frying-pan, and fill it about half full of water. Let the water be perfectly clean, not a particle of dust or dirt upon it. Put some salt into the water. Break each egg into a separate tea-cup, and slip it gently from the cup into the water. There is a knack in doing this, without causing the egg to spread or become ragged. A good way consists in allowing a little water to enter the cup and get below the egg, which sets the egg to a certain extent, before it is allowed to lie freely in the water. If the water be about boiling point, one minute is sufficient to dress the egg; but the eye is the best guide: the yolk must retain its liquid state, lying in the centre of the white. Have buttered toasted bread prepared on a dish, and cut in pieces rather larger than the egg; then take up the eggs carefully with a small slice, pare off any ragged parts from the edges, and lay them on the bread. They may be laid on slices of fried bacon, when preferred.

Buttered Eggs.—Put a piece of butter in a saucepan, and melt it, adding a little milk. Break the eggs into a basin, and pour them into the saucepan. Season with salt and pepper, and continue stirring the eggs till they are sufficiently dressed. Serve on pieces of toasted bread.

Omelettes.—Omelettes are composed of eggs and any thing that the fancy may direct to flavour and enrich them. For a common omelette, take six eggs, and beat them well with a fork in a basin; add a little salt. Next, take a little finely chopped parsley, finely chopped eschalot or onion, and two ounces of butter cut into small pieces, and mix all this with the egg. Set a frying-pan on the fire with a piece of butter in it; as soon as the butter is melted, pour in the omelette, and continue to stir it till it assume the appearance of a firm cake. When dressed on one side, turn it carefully, and dress it on the other. It will be dressed sufficiently when it is lightly browned. Serve it on a dish. The flavour may be varied, by leaving out the parsley and onion, and putting in finely chopped tongue or ham, oysters, shrimps, grated cheese, or other ingredients.

Pancakes.—Pancakes are made of eggs, flour, and milk, in the proportion of a tablespoonful of flour to each egg. To make two small pancakes, take two eggs, and beat them well, and add to them a little milk. Then take two tablespoonfuls of flour, and work it into a batter with the egg and milk; add a little salt. Set a clean frying-pan on the fire, and put a piece of butter or lard into it. When the butter is quite hot, pour in the batter. Shake it frequently, to prevent it from sticking. When the under side is of a light brown, turn it. Serve the pancakes folded, with sugar strewn between the folds. This is the way of dressing the common pancake; when required to be lighter, use more egg and less flour; and grated nutmeg may be added.

Fritters.—Make a batter of eggs, flour, and milk, as for pancakes, but with a little more flour. Apple fritters are made by cutting large pared apples in slices, dipping

the slices in the batter, and frying them separately. They are done when lightly browned on both sides. Another, and perhaps more common way, is to cut the apples in small pieces, and mix them with the batter, frying them, a spoonful in each fritter. Fritters may be made with currants in the same manner. Serve all fritters with sugar sprinkled over them.

Barley Water.—This is a drink used by invalids, and is made from pearl barley. To make a quart, wash a tea-cupful of pearl barley in cold water, after which throw away the water. Put the washed barley into a saucepan with a little boiling water; after boiling a few minutes, throw this water away also. Then fill up the saucepan with two quarts of boiling water, and continue boiling until there is only one quart left. It may be flavoured with lemon or jelly.

Gruel.—Gruel for invalids is made either from grits or from oatmeal. A pint may be made as follows:—If from grits (called in London Embden grits) or groats, put on about two tablespoonfuls in rather more than a pint of water; let it boil for at least two hours. When boiled, strain it through a hair sieve. If from fine oatmeal, such as is sold in England, take about a tablespoonful and a half, and mix with it gradually about a pint of cold water, braying it as you mix, and boil it for half an hour. It is now done, and requires no straining. If the oatmeal be coarse, such as is used in Scotland, take a tea-cupful and put it into a basin. Mix it well with a small quantity of water. Pour this water off, then take another water from it: in this manner about a quart should be taken, the coarser particles of the meal being rejected. Put all the waters into a saucepan, and boil for twenty minutes, stirring the whole time. It is now ready, and, like other kinds of gruel, may be seasoned according to taste.

Lemonade.—Take a quart of boiling water, and add to it five ounces of lump sugar, the yellow rind of a lemon rubbed off with a bit of sugar, and the juice of three lemons. Stir all together, and let it stand till cool. Two ounces of cream of tartar may be used instead of the lemons, boiling water being poured upon it.

To boil Rice for Curry.—It is customary to serve boiled rice along with dishes which have been seasoned or stewed with curry. When rice is required for this purpose, it should not be soft or pulpy as in boiling for puddings; each grain should retain its perfect individual form, though swelled to nearly its fullest size. After picking and washing the rice, put it into boiling water, and let it boil smartly for about twelve minutes. Just before taking it out, put in a tablespoonful of salt. Drain the rice in a cullinder; then shake it gently out upon a doubled cloth, and lay it before the fire for a few minutes, with a fold of cloth over it. By this process the water will be absorbed from it, and it will be ready for dishing. Pour it lightly into the dish.

To make a Stuffing.—Roast veal, fowls, turkey, and some other things, require a stuffing. These stuffings have been alluded to in various recipes in the preceding pages, and may here be expressly defined. Take a quarter of a pound of the crumbs of stale white bread, a quarter of a pound of chopped beef suet or marrow, as much chopped parsley as will lie on a tablespoon, about half a spoonful of chopped sweet marjoram, and a little grated lemon peel, pepper, and salt. Mix all these thoroughly together, with one beat egg and a little sweet milk. This forms a species of dough in sufficient quantity for a small turkey or large fowl.

Force-meat Balls.—These are balls formed of stuffing, used as a garnish for roast veal or veal cutlets. Make a stuffing like the above, but instead of being wet with one egg and milk, wet the mixture with two eggs. Roll the dough into small balls, about the size of nutmegs. Roll them in flour, and fry them with a little lard, butter, or dripping. When required to be more savoury, the composition may be enriched with a little chopped ham, tongue, or sausage meat.

PROVERBS AND OLD SAYINGS.

SCRIPTURAL PROVERBS.

A FALSE balance is an abomination to the Lord ; but a just weight is his delight.
A fool uttereth all his mind ; but a wise man keepeth it till afterwards.
A fool's wrath is presently known ; but a prudent man covereth shame.
A good name is rather to be chosen than great riches, and loving favour rather than silver and gold.
A man that has friends must show himself friendly ; and there is a friend that sticketh closer than a brother.
A man of understanding holdeth his peace.
A man's pride shall bring him low ; but honour shall uphold the humble in spirit.
A merry heart doeth good like a medicine ; but a broken spirit drieth the bones.
A righteous man regardeth the life of his beast ; but the tender mercies of the wicked are cruel.
A soft answer turneth away wrath ; but grievous words stir up anger.
A virtuous woman is a crown to her husband ; but she that maketh ashamed is as rottenness in his bones.
A wise son maketh a glad father ; but a foolish son is the heaviness of his mother.
A word fitly spoken is like apples of gold in pictures of silver.
As a bird that wandereth from her nest, so is a man that wandereth from his place.
As a dog returneth to his vomit, so a fool returneth to his folly.
As a jewel of gold on a swine's snout, so is a fair woman who is without discretion.
As a madman who casteth firebrands, arrows, and death, so is the man that deceiveth his neighbour, and saith, Am not I in sport ?
As the crackling of thorns under a pot, so is the laughter of the fool.
As the whirlwind passeth, so is the wicked no more ; but the righteous is an everlasting foundation.
As vinegar to the teeth, and as smoke to the eyes, so is the sluggard to them that send him.

Be thou diligent to know the state of thy flocks, and look well to thy herds : for riches are not for ever.
Before honour is humility.
Better is a dry morsel and quietness therewith, than a house full of sacrifices with strife.
Better is a dinner of herbs where love is, than a stalled ox and hatred therewith.
Better is a little with righteousness, than great revenues without right.
Blessings are upon the head of the just ; but violence covereth the mouth of the wicked.

Boast not thyself of to-morrow ; for thou knowest not what a day may bring forth.

By much slothfulness the building decayeth ; and through idleness of the hands, the house droppeth through.

By pride cometh contention.

Cast thy bread upon the waters, for thou shalt find it after many days.

Even a fool, when he holdeth his peace, is counted wise ; and he that shutteth his lips is esteemed a man of understanding.

Faithful are the wounds of a friend ; but the kisses of an enemy are deceitful.

Favour is deceitful, and beauty is vain ; but a woman that feareth the Lord, she shall be praised.

Fear God, and keep his commandments : for this is the whole duty of man.

For men to search their own glory* is not glory.

Go from the presence of a foolish man, when thou perceivest not in him the lips of knowledge.

Go to the ant, thou sluggard ; consider her ways and be wise.

God hath made man upright, but they have sought out many inventions.

He becometh poor that dealeth with a slack hand ; but the hand of the diligent maketh rich.

He that observeth the wind shall not sow, and he that regardeth the clouds shall not reap.

He that passeth by, and meddleth with strife belonging not to him, is like one that taketh a dog by the ears.

He that is slow to anger is better than the mighty, and he that ruleth his spirit than he that taketh a city.

He that loveth pleasure shall be a poor man : he that loveth wine and oil shall not be rich.

He that is greedy of gain troubleth his own house ; but he that hateth gifts shall live.

He that is of a merry heart hath a continual feast.

He that is first in his own cause seemeth just ; but his neighbour cometh and searcheth him.

He that hath pity upon the poor lendeth unto the Lord ; and that which he hath given will he pay him again.

He that hideth hatred with lying lips, and he that uttereth a slander, is a fool.

He that spareth the rod hateth his son ; but he that loveth him chasteneth betimes.

He that gathereth in summer is a wise son ; but he

* To talk of their own doings.

that sleepeth in harvest is a son that causeth shame.
 He that walketh uprightly walketh surely; but he that perverteth his ways shall be known.
 He that is surety for a stranger, shall smart for it; and he that hateth suretyship is sure.
 He that keepeth [silent] his mouth, keepeth his life; but he that openeth wide his lips shall have destruction.
 He that troubleth his own house shall inherit the wind; and the fool shall be servant of the wise of heart.
 Heaviness in the heart of a man maketh it stoop; but a good word maketh it glad.
 Hell and destruction are never full; so the eyes of man are never satisfied.
 His own iniquities shall take the wicked himself, and he shall be holden with the cords of his own sins.
 Hope deferred maketh the heart sick.

If sinners entice thee, consent thou not.
 If the iron be blunt, and he do not whet the edge, then must he put to more strength; but wisdom is profitable to direct.*
 If thine enemy be hungry, give him bread to eat; and if he be thirsty, give him water to drink: for thou shalt heap coals of fire upon his head, and the Lord shall reward thee.
 If thou faint in the day of adversity, thy strength is small.
 If ye cast pearls before swine, they will turn again and rend ye.
 In all labour there is profit; but the talk of the lips tendeth only to penury.
 Iron sharpeneth iron; so a man sharpeneth the countenance of his friend.
 It is nought, it is nought, saith the buyer; but when he is gone his way, then he boasteth.
 It is better to dwell in a corner of the house-top, than with a brawling woman in a wide house.

Let another man praise thee, and not thine own mouth; a stranger, and not thine own lips.
 Love not sleep, lest thou come to poverty: open thine eyes, and thou shalt be satisfied with bread.

Much food is in the tillage of the poor: but there is that is destroyed for want of judgment.

Of making many books there is no end; and much study is a weariness of the flesh.

Pride goeth before destruction, and an haughty spirit before a fall.

Remove not the old landmark; and enter not into the fields of the fatherless.

Reprove not a scorner lest he hate thee; rebuke a wise man and he will love thee.

Righteousness exalteth a nation; but sin is a reproach to any people.

Say not unto thy neighbour, Go, and come again, and to-morrow I will give, when thou hast it by thee.

Seest thou a man diligent in his business: he shall stand before kings; he shall not stand before mean men.†

Seest thou a man that is hasty in his words: there is more hope of a fool than of him.

Strive not with a man without cause, if he have done thee no harm.

The blessing of the Lord, it maketh rich, and he addeth no sorrow with it.

The curse causeless shall not come.
 The drunkard and the glutton shall come to poverty; and drowsiness shall clothe a man with rags.
 The hand of the diligent shall bear rule; but the slothful shall be under tribute.
 The labour of the righteous tendeth to life, the fruit of the wicked to sin.
 The memory of the just is blessed; but the name of the wicked shall rot.
 The race is not to the swift, nor the battle to the strong.
 The rich man is wise in his own conceit; but the poor that hath understanding searcheth him out.
 The rich man's wealth is his strong city; the destruction of the poor is their poverty.
 The rich ruleth over the poor; and the borrower is servant to the lender.
 The simple believeth every word; but the prudent man looketh well to his going.
 The sleep of a labouring man is sweet, whether he eat little or much; but the abundance of the rich will not suffer him to sleep.
 The sluggard will not plough by reason of the cold; therefore shall he beg in harvest, and have nothing.
 The slothful man saith, There is a lion without; I shall be slain in the streets.
 The poor is hated even of his neighbour; but the rich hath many friends.
 The profit of the earth is for all: the king himself is served by the field.
 The upright shall dwell in the land, and the perfect shall remain in it. But the wicked shall be cut off from the earth, and the transgressors shall be rooted out of it.
 The wicked flee when no man pursueth;* but the righteous are bold as a lion.
 The wise shall inherit glory; but shame shall be the promotion of fools.
 There is that maketh himself rich, yet hath nothing; there is that maketh himself poor, yet hath great riches.
 There is that scattereth, and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty.
 To all the living there is hope: a living dog is better than a dead lion.
 Train up a child in the way he should go, and when he is old he will not depart from it.
 Treasures of wickedness profit nothing; but righteousness delivereth from death.
 Wealth maketh many friends; but the poor is separated from his neighbour.
 Whatsoever thy hand findeth to do, do it with thy might; for there is no work, nor device, nor knowledge, nor wisdom in the grave, whither thou goest.
 When goods increase, they are increased that eat them; and what good is there to the owners thereof, saving the beholding of them with their eyes.
 Where no counsel is, the people fail; but in the multitude of counsellors there is safety.
 Where no wood is, then the fire goeth out; so where there is no tale-bearer, the strife ceaseth.
 When pride cometh, then cometh shame; but with the lowly is wisdom.
 Who can find a virtuous woman? for her price is far above rubies.
 Whoso findeth a wife findeth a good thing, and obtaineth favour of the Lord.
 Wine is a mocker, strong drink is raging; and whosoever is deceived thereby is not wise.
 Withdraw thy foot from thy neighbour's house, lest he be weary of thee, and so hate thee.
 Withhold not good from them to whom it is due, when it is in the power of thine hand to do it.

Yet a little sleep, a little slumber, a little folding of the hands to sleep: so shall thy poverty come as one that travelleth, and thy want as an armed man.

* Conscience makes cowards of us all.—Shakespeare.

* Knowledge is power.—Bacon.

† Anciently, in the east, it was an honour to be permitted to stand in the presence of kings, as it is to sit before them in our own country.

ENGLISH PROVERBS.

A bad workman quarrels with his tools.
 A bird in the hand is worth two in the bush.
 A happy heart makes a blooming visage.
 Absence cools moderate passions, and inflames violent ones.
 A burden which one chooses is not felt.
 A cat may look at a king.
 Aching teeth are ill tenants.
 A chip of the old block.
 A clear conscience fears no accusation.
 A contented mind is a continual feast.
 A creaking door hangs long on the hinges.
 A day after the feast.
 A drowning man will catch at a straw.
 Adversity flattereth no man.
 A fat kitchen makes a lean will.
 A fault confessed is half redressed.
 A fool and his money are soon parted.
 A fool can make money; it requires a wise man to spend it.
 A fool may give a wise man counsel.
 A fool's bolt is soon shot.
 After death, the doctor.
 After dinner sit a while, after supper walk a mile.
 After meat, mustard.
 A friend in need is a friend indeed.
 A full purse never lacks friends.
 A gentleman without a living is like a pudding without suet.
 A good layer-up is a good layer-out.
 A good maxim is never out of season.
 A good name keeps its lustre in the dark.
 A good servant makes a good master.
 A good word is as soon said as an ill one.
 A goose cannot graze after him.
 A great dowry is a bed full of troubles.
 Agues come on horseback, but go away on foot.
 A guilty conscience needs no accuser.
 A hair of the dog that bit him.
 A handful of good life is better than a bushel of learning.
 A hungry man's an angry man.
 A king's favour is no inheritance.
 A libertine's life is not a life of liberty.
 A lie has no legs, but scandal has wings.
 A light-heeled mother makes a heavy-heeled daughter.
 A light purse is a heavy curse.
 A little body doth often harbour a great soul.
 A little leak will sink a great ship.
 A little pot is soon hot.
 All are not friends that speak us fair.
 All are not hunters that blow the horn.
 All are not thieves that dogs bark at.
 All feet tread not in one shoe.
 All gone to sixes and sevens [confusion and ruin].
 All is fish that comes to the net.
 All is not gain that is got into the purse.
 All is not gold that glitters.
 All lay load on the willing horse.
 All the honesty is in the parting.
 All the fat's in the fire.
 All things are soon prepared in a well-ordered house.
 All work and no play, makes Jack a dull boy.
 Almost and very nigh, save many a lie.
 Always put the saddle on the right horse.
 A man forewarned is forearmed.
 A man may buy gold too dear.
 A man may cause his own dog to bite him.
 A man may hold his tongue in an ill time.
 A man may lose his goods for want of demanding them.
 A man must ask his wife leave to thrive.
 A man never surfeits of too much honesty.
 A man without reason is a beast in season.
 A miss is as good as a will.
 An apple, an egg, and a nut, you may eat after a slut.
 An empty purse fills the face with wrinkles.
 An evil lesson is soon learned.
 Anger dieth quickly with a good man.
 An honest man's word is as good as his bond.
 An hour in the morning is worth two in the afternoon.
 A nice wife and a backdoor often make a rich man poor.
 An idle brain is the devil's workshop.
 An oak is not felled with one blow.
 An obedient wife commands her husband.
 A nod from a lord is a breakfast for a fool.
 An old knave is no babe.
 An old sack asketh much patching.
 An ounce of mother-wit is worth a pound of clergy.
 Antiquity is not always a mark of verity.
 An unlawful oath is better broke than kept.
 Any thing for a quiet life.
 A penny saved is a penny earned.
 A pin a-day is a groat a-year.
 A pitcher goes often to the well, but is broken at last.
 A quiet conscience sleeps in thunder.
 A quiet tongue shows a wise head.
 A rolling stone gathers no moss.
 A rotten apple injures its companions.
 A rotten sheep infects the whole flock.
 A single fact is worth a ship-load of argument.
 A small pack becomes a small pedlar.
 A small spark makes a great fire.
 A smart reproof is better than smooth deceit.
 A spur in the head is worth two in the heel.
 As the bell is, so is the clapper.
 As the crow is, the egg will be.
 As the fool thinks, the bell clinks.
 As the old cock crows, the young cock learns.
 A stitch in time saves nine.
 As welcome as flowers in May.
 As you make your bed, so must you lie on it.
 As you sow, so you shall reap.
 A tree is known by its fruit.
 A wager is a fool's argument.
 A wilful man will have his way.
 A willing mind makes a light foot.
 A word before is worth two behind.
 Aye be as merry as you can.
 Bachelors' wives and maids' children are always well taught.
 Beauty is a blossom.
 Beauty is no inheritance.
 Before thou marry, be sure of a house wherein to tarry.
 Beggars have no right to be choosers.
 Be it for better, or be it for worse, be ruled by him that beareth the purse.
 Be not too hasty to outbid another.
 Be slow to promise, and quick to perform.
 Better do it than wish it done.
 Better go about than fall into the ditch.
 Better known than trusted.
 Better late than never.
 Better ride on an ass that carries me, than a horse that throws me.
 Better to be alone than in bad company.
 Better to be beaten than to be in bad company.
 Better to bend than to break.
 Better to go to bed supperless than to rise in debt.
 Between two stools we come to the ground.
 Birds of a feather flock together.
 Birth is much, but breeding is more.
 Borrowed garments never fit well.
 Brag is a good dog, but Holdfast is better.
 Bread at pleasure, drink by measure.
 Brevity is the soul of wit.
 Building and marrying of children are great wasters.
 Burning the candle at both ends.
 Business is the salt of life.
 Buy at a market, but sell at home.
 By others' faults wise men correct their own.
 "Can do" is easily carried.

Care killed a cat.
 Carrying coals to Newcastle.
 Catch not at the shadow, and lose the substance.
 Catch the bear before you sell his skin.
 Change of fortune is the lot of life.
 Charity begins at home, but does not end there.
 Cheating play never thrives.
 Children and chickens must be always picking.
 Children are uncertain comforts.
 Children suck the mother when they are young, and the father when they are old.
 Climb not too high, lest the fall be the greater.
 Confession of a fault makes half amends for it.
 Confine your tongue, lest it confine you.
 Conscience is never dilatory in her warnings.
 Conscience is the chamber of justice.
 Constant occupation prevents temptation.
 Content is the true philosophers' stone.
 Contentment to the mind is as light to the eye.
 Conviviality should ever be free from intemperance.
 Courtesy on one side never lasts long.
 Covet not that which belongs to others.
 Craft bringeth nothing home.
 Custom is a second nature.
 Cut and come again.
 Cut your coat according to your cloth.

Daub yourself with honey, and you will have plenty of flies.
 Death is deaf, and hears no denial.
 Death keeps no calendar.
 Debt is the worst kind of poverty.
 Deeds are fruits, words are but leaves.
 Deep rivers move with silent majesty, shallow brooks are noisy.
 Defer not till the evening what the morning may accomplish.
 Delays are dangerous.
 Deliberate slowly, execute promptly.
 Depend not on fortune, but on conduct.
 Dependence is a poor trade to follow.
 Deride not any man's infirmities.
 Desires are nourished by delays.
 Deserve success, and you shall command it.
 Despise none, despair of none.
 Diligence is the mistress of success.
 Diseases are the interests paid for pleasures.
 Do as the most do, and fewest will speak evil of you.*
 Do as you would be done by.
 Dogs wag their tails not so much in love to you as to your bread.
 Doing nothing is doing ill.
 Do not burn daylight upon it.
 Do not halloo till you are out of the wood.
 Do not make fish of one and flesh of another.
 Do not rip up old sores.
 Do not spur a free horse.
 Do not throw your opinions in every body's teeth.
 Don't be all your days trotting on a cabbage leaf.
 Don't buy a pig in a poke.
 Don't measure other people's corn by your bushel.
 Don't neglect to feather your nest.
 Don't run away with more than you can carry.
 Don't value a gem by what it is set in.
 Do what thou oughtest, and come what can.
 Down with the dust [pay the money].
 Drunkenness is a pair of spectacles to see the devil and all his works.
 Drunkenness reduces a man below the standard of a brute.

Eagles fly alone, but sheep flock together.
 Early to bed, and early to rise,
 Makes a man healthy, wealthy, and wise.
 Eat what you like, but pocket nothing.
 Empty vessels make the greatest sound.
 Enough is as good as a feast.

Entertain honour with humility, and poverty with patience.
 Evening oats are good morning's fodder.
 Ever drunk ever dry.
 Ever spare and ever have.
 Every bean hath its black.
 Every body's business is nobody's business.
 Every couple is not a pair.
 Every dog has his day.
 Every herring must hang by its own head.
 Every Jack has his Gill.
 Every man is the architect of his own fortune.
 Every one for himself, and God for us all.
 Every one puts his fault on the times.
 Every one to their liking, as the old woman said when she kissed her cow.
 Every path hath a puddle.
 Every shoe fits not every foot.
 Every thing hath an end, and a pudding hath two.
 Every thing is good in its season.
 Every thing is the worse for wearing.
 Example teaches more than precept.
 Experience is the mother of science.
 Experience teaches fools.
 Evil communications corrupt good manners.
 Evil gotten evil spent.

Faint heart never won fair lady.
 Fair and softly go far in a day.
 Fair words make fools fain.
 Fall not out with a friend for a trifle.
 False friends are worse than open enemies.
 Fancy may bolt bran and think it flour.
 Far-fetched and dear-bought is good for ladies.
 Fat paunches make lean pates.
 Fat sorrow is better than lean sorrow.
 Few take care to live well, but many to live long.
 Fiddler's fare—meat, drink, and money.
 Fine feathers make fine birds.
 Fine words butter no parsnips.
 Fire and water are good servants, but bad masters.
 Fire is not to be quenched with tow.
 First deserve and then desire.
 Fly pleasure, and it will follow thee.
 Fools make feasts, and wise men eat them.
 Fools should never see half-done work.
 Fools tie knots, and wise men loose them.
 Fools will be meddling.
 Forbearance is no acquittance.
 Forgive and forget.
 Forgive any sooner than thyself.
 Fortune favours the brave.
 Fortune has no power over discretion.
 Fortune knocks once at least at every man's gate.
 For want of company, welcome trumpery.
 From fame to infamy is a beaten road.

Gather thistles, expect prickles.
 Gentry sent to market will not buy one bushel of corn.
 Get thy spindle and distaff ready, and God will send flax.
 Give a dog an ill name and hang him.
 Give a rogue rope enough, and he will hang himself.
 Give it plenty of elbow grease [hard rubbing].
 Give the devil his due.
 God help the rich, the poor can beg.
 God helps those who help themselves.
 God send you more wit, and me more money.
 God tempers the wind to the shorn lamb.
 Go farther and fare worse.
 Good counsel is above all price.
 Good harvests make men prodigal, bad ones provident.
 Good to be merry at meat.
 Good ware makes quick markets.
 Good wine needs no bush.
 Good words cost nothing, but are worth much.
 Goods are not theirs who enjoy them.
 Gossiping and lying go hand in hand.

* In most cases this would be a bad advice.

PROVERBS AND OLD SAYINGS.

Grasp all, lose all.
Great barkers are no biters.
Great cry and little wool.
Great gain and little pain make a man soon weary.

Half a loaf is better than no bread.
Handsomeness is that handsomeness does.
Happy is he whose friends were born before him.
Happy is he who knows his follies in his youth.
Happy is the wooing that is not long in doing.
Harm watch, harm catch.
Hasty resolutions seldom speed well.
Have not thy cloak to make when it begins to rain.
Hear twice before you speak once.
He dances well to whom fortune pipes.
He doubles his gift who gives in time.
He fights with his own shadow.
He giveth twice that gives in a trice.
He has a bee in his bonnet.
He has brought his noble to ninepence.
He has had a bite upon his bridle.
He is a wise man who speaks little.
He is proper that hath proper conditions.
He knows not a B from a bull's foot.
He knows not a hawk from a hand-saw.
He lacks most that longs most.
Hell is paved with good intentions.
Help the lame dog over the stile.
He liveth long that liveth well.
He'll find some hole to creep out at.
He loses nothing for the asking.
He loseth his thanks who promiseth and delayeth.
He loseth nothing that keeps God for his friend.
He loves roast meat well that licks the spit.
He may well be contented who needs neither borrow nor flatter.
He must needs run whom the devil drives.
He must stoop that hath a low door.
He plays well that wins.
He's a Jack in office.
He's gone upon a sleeveless errand.
He that always complains is never pitied.
He that blows in the dust fills his eyes.
He that falls in an evil cause, falls in the devil's frying-pan.
He that goes a-borrowing goes a-sorrowing.
He that has no shame has no conscience.
He that has no silver in his purse should have silver on his tongue.
He that hath a good harvest may be content with some thistles.
He that is angry is seldom at ease.
He that is warm thinks all are so.
He that lendeth loseth double. [Loses both his money and his friend.]
He that licks honey from thorns pays too dear for it.
He that lies down with dogs, must expect to rise with fleas.
He that lives not well one year sorrows for it seven.
He that liveth wickedly can hardly die honestly.
He that reckons without his host must reckon again.
He that runs fast will not run long.
He that runs in the night stumbles.
He that sows not corn plants thistles.
He that stays in the valley will never get over the hill.
He that will not be saved needs no preacher.
He that will not be counselled cannot be helped.
He that will steal an egg will steal an ox.
He that would thrive must rise at five, he that has thriven may lie till seven.
He was born with a silver spoon in his mouth.
He who is hasty fishes in an empty pond.
He who knows himself best esteems himself least.
He who lies long in bed his estate feels it.
He who marrieth for wealth doth sell his liberty.
He who rises late never does a good day's work.
He who runs after a shadow has a wearisome race.
He who sows brambles must not go barefoot.

He who spends all he gets is in the highroad to beggary.
He who swims in sin will sink in sorrow.
He who would catch fish must not mind getting wet.
He who would reap well must sow well.
Hiders are good finders.
His bread is buttered on both sides.
His eye is bigger than his belly.
His tongue's no slander.
Home is home though it be ever so homely.
Hope is a good breakfast, but a bad supper.
Hot love is soon cold.
Hot sup, hot swallow.
Humility is the foundation of all virtue.
Hunger is the best sauce.
Hungry dogs eat dirty puddings.

I can see as far into a millstone as the picker.
Idle folks have the most labour.
Idle folks have the least leisure.
Idleness is the greatest prodigality.
Idleness is the parent of want and shame.
Idleness is the root of all evil.
Idleness is the sepulchre of a living man.
If every one would mend one, all would be amended.
If the brain sows not corn, it plants thistles.
If the cap fit, wear it.
If the mountain will not come to Mahomet, Mahomet must go to the mountain.
If things were to be done twice, all would be wise.
If we subdue not our passions, they will subdue us.
If wishes were horses, beggars would ride.
If you give an inch, he will take an ell.
If you have too many irons in the fire, some of them will burn.
If you would enjoy the fruit, pluck not the flower.
Ignorance is the parent of many injuries.
I have a crow to pluck with him.
I have lived too near a wood to be frightened by owls.
I have other fish to fry.
I'll trust him no farther than I can fling him.
Ill examples are like contagious diseases.
Ill-gotten goods seldom prosper.
Ill news travels apace.
Ill wedding and ill wintering tame both man and beast.
Ill weeds grow apace.
In a calm sea every man is a pilot.
In at one ear and out at the other.
In vain he craves advice that will not follow it.
Inconstancy is the attendant of a weak mind.
It costs more to revenge injuries than to bear them.
It cuts both ways, like a two-edged sword.
It is a bad horse that refuses to carry his provender.
It is a long road that has no turning.
It is an ill wind that blows nobody good.
It is better to do well, than to say well.
It is good to begin well, but better to end well.
It is less painful to learn in youth than to be ignorant in age.
It is never too late to learn.
It is no small conquest to overcome yourself.
It is not the cowl that maketh the friar.
It's a bad cause that none dare speak in.
It's a bad sack will abide no clouting.
It's a good horse that never stumbles.
It's a poor sport that's not worth the candle.
It's a sad heart that never rejoices.
It's a wise child that knows its own father.
It's an ill procession where the devil holds the candle.
It's easy to bowl down hill.
It's ill healing an old sore.
It's ill shaving against the wool.
It's merry in the hall when beards wag all.
It's more painful to do nothing than something.
It's not the gay coat makes the gentleman.
It's possible for a ram to kill a butcher.
It's wit to pick a lock and steal a horse, but wisdom to let them alone.

Jack Nokes and Tom Stiles.
 Jack of all trades and master of none.
 Jestings lies bring serious sorrows.
 Judge not of a ship as he lies on the stocks.
 Judge not of men or things at first sight.

Keep a thing seven years, and you will find a use for it.
 Keep counsel thyself first.
 Keep good men company, and you shall be of the number.
 Keep no more cats than will catch mice.
 Keep the bowels open, the head cool, and the feet warm, and a fig for physicians.
 Keep thy shop, and thy shop will keep thee.
 Keep your tongue within your teeth.
 Kill two birds with one stone.
 Kindness is lost upon an ungrateful man.
 Kindnesses, like grain, increase by sowing.
 Kissing goes by favour.
 Knavery may serve a turn, but honesty is best in the end.

Land was never lost for want of an heir.
 Lazy folks take the most pains.
 Least said is soonest mended.
 Lend thy horse, and thou mayest have back his skin.
 Let every pedlar carry his own burden.
 Let every tub stand on its own bottom.
 Let not your tongue cut your throat.
 Let sleeping dogs lie.
 Let the cobbler stick to his last.
 Let them laugh that win.
 Life is half spent before we know what it is.
 Life without a friend is death without a witness.
 Light come, light go.
 Lips however rosy must be fed.
 Little and often fills the purse.
 Little boats must keep near shore.
 Little pitchers have great ears.
 Little sticks kindle the fire, but great ones put it out.
 Live and let live.
 Live not to eat, but eat to live.
 Lowly set, richly worn.
 Lock the stable door when the steed is stolen.
 Long looked-for comes at last.
 Look before you leap.
 Look to the main chance.
 Look twice ere you determine once.
 Lookers-on see more than players.
 Losers are always in the wrong.
 Love asks faith, and faith asks firmness.
 Love me, love my dog.
 Lovers live by love as larks by leeks. [Ironical.]
 Lucky men need little counsel.

Make a virtue of necessity.
 Make hay while the sun shines.
 Make not your sail too large for your ship.
 Make the best of a bad bargain.
 Making a toil of a pleasure.
 Man doth what he can, and God what he will.
 Man proposes, God disposes.
 Manners often make fortunes.
 Many a slip betwixt the cup and the lip.
 Many a true word is spoken in jest.
 Many can pack the cards that cannot play.
 Many go out for wool and come home shorn.
 Many hands make light work.
 Many words will not fill the bushel.
 Marry in haste, repent at leisure.
 Marry your sons when you will, your daughters when you can.
 Mills and wives are ever wanting.
 Mischiefs come by the pound, and go away by the ounce.
 Misfortunes seldom come alone.
 Misreckoning is no payment.
 Modesty is the handmaid of virtue.
 Money makes the mare to go.

Money will do more than my lord's letter.
 More afraid than hurt.
 Much is expected where much is given.
 Much water goes by the mill the miller knows not of.
 Much would have more and lost all.
 Muffled cats are bad mousers.
 Murder will out.
 My son is my son till he gets him a wife,
 But my daughter's my daughter all the days of her life.
 Necessity is the mother of invention.
 Neither praise nor dispraise thyself; thine actions serve the turn.
 Never carry two faces under one hood.
 Never fall out with your bread and butter.
 Never find any thing before it is lost.
 Never fish in troubled waters.
 Never light your candle at both ends.
 Never look a gift horse in the mouth.
 Never make a mountain of a mole-hill.
 Never quit certainty for hope.
 Never ride a free horse to death.
 Never sound the trumpet of your own praise.
 Never split against the grain.
 Never tread on a sore toe.
 Never trust to a broken staff.
 Never venture out of your depth till you can swim.
 Never wade in unknown waters.
 New brooms sweep clean.
 New lights often come through cracks in the tiling.
 New lords, new laws.
 Next to love, quietness.
 No alchemy is equal to saving.
 No man can serve two masters.
 No man should live like a toad under a harrow.
 No mill, no meal.
 None are so deaf as those that will not hear.
 None knows the weight of another's burden.
 None so blind as those who will not see.
 No pot is so ugly as not to find a cover.
 No receiver, no thief.
 No rose without a thorn.
 Nothing comes out of the sack but what was in it.
 Nothing dries sooner than tears.
 Nothing down, nothing up.
 Nothing is impossible to a willing mind.
 Nothing venture, nothing win.

Of all studies, study your present condition.
 Of all the crafts, to be an honest man is the master craft.
 Of all prodigality, that of time is the worst.
 Of two evils choose the least.
 Old bees yield no honey.
 Old birds are not to be caught with chaff.
 Old friends and old wine are best.
 Old friends to meet, old wine to drink, and old wood to burn.
 Old reckonings breed new disputes.
 One bad example spoils many good precepts.
 One barber shaves not so close but another finds work.
 One eye-witness is better than ten hearsays.
 One flower makes no garland.
 One good turn deserves another.
 One half the world knows not how the other half lives.
 One hour's sleep before midnight is worth two after.
 One is not so soon healed as hurt.
 One man may steal a horse, when another may not look over the hedge.
 One man's meat is another's poison.
 One nail drives out another.
 One never loses by doing a good turn.
 One ounce of discretion is worth a pound of wit.
 One scabbied sheep will mar a flock.
 One swallow makes not a spring, nor one woodcock a winter.
 One tale is good till another is told.
 Open rebuke is better than secret hatred.

PROVERBS AND OLD SAYINGS.

Opportunity makes the thief.
 Opportunities neglected are irrecoverable.
 Our own opinion is never wrong.
 Out of debt, out of danger.
 Out of sight, out of mind.
 Out of the frying-pan into the fire.

Passion is a fever that leaves us weaker than it finds us.

Passion is ever the enemy of truth.
 Patience and time run through the longest day.
 Patience is a flower that grows not in everyone's garden.
 Patience is a plaster for all sores.
 Pay as you go.
 Penny wise and pound foolish.
 People who live in glass houses should never throw stones.

Perfection is the point at which all should aim.
 Pettulant contentions engender malice.
 Plain dealing's a jewel.
 Positive men are most often in error.
 Possession is nine points of the law.
 Poverty makes a man acquainted with strange bedfellows.

Poverty parts friends.
 Praise a fair day at night.
 Praise the sea, but keep on land.
 Prevention is better than cure.
 Prettiness dies quickly.
 Pride of heart foreruns destruction.
 Pride will have a fall.
 Procrastination is the thief of time.
 Promise little and do much.
 Promises are too much like pie-crust.
 Provide for the worst, the best will save itself.
 Pry not into the affairs of others.
 Pull hair and hair, and you'll make the carle bald.
 Put no faith in tale-bearers.

Quick at meat, quick at work.
 Quick resentments are often fatal.
 Quick returns make rich merchants.
 Quit not certainty for hope.

Raise no more spirits than you can conjure down.
 Ratify promises by performances.
 Ready money will away.
 Reckless youth makes rueful age.
 Remove an old tree and it will wither.
 Rome was not built in a day.
 Rule the appetite and temper the tongue.

Safe bind, safe find.
 Sauce for the goose is sauce for the gander.
 Saving at the spigot and spending at the bung.
 Say no ill of the year till it be past.
 Saying and doing are two things.
 Search others for their virtues, thyself for their faults.
 See a beggar and catch a louse.
 Seeing is believing.
 Seek till you find, and you'll not lose your labour.
 Seldom seen, soon forgotten.
 Self-preservation is the first law of nature.
 Set a thief to take a thief.
 Shameless craving must have shameless way.
 Sharp stomachs make short graces.
 She shows many more airs than graces.
 Show me a liar, and I will show you a thief.
 Short reckonings make long friends.
 Silence doth seldom any harm.
 Silks and satins put out the fire in the kitchen.
 Sit in your place and none will make you rise.
 Sleep without supper and wake without owing.
 Sloth is the mother of poverty.
 Soldiers in peace are like chimneys in summer.
 Soon ripe, soon rotten.
 Soon well, long ill.
 Sooner said than done.
 Sorrow will pay no debt.

Sour grapes, as the fox said when he could not reach them.

Spare well and spend well.
 Spare when you are young and spend when you are old.
 Speak the truth and shame the devil.
 Speech is the gift of all, but thought of few.
 Stars are not seen by sunshine.
 Stick your opinions on no person's sleeve.
 Stretch your legs according to your coverlet.
 Strike while the iron is hot.
 Study to be worthy of your parents.
 Such a welcome, such a farewell.
 Such as the tree is, such is the fruit.

Take care of the pence, and the pounds will take care of themselves.

Take heed of an ox before, an ass behind, and a knave on all sides.

Take heed will surely speed.

Take the will for the deed.

Take time by the forelock.

Talk of the devil and he'll appear.

Talking pays no toll.

Tell me the company you keep, and I'll tell you what you are.

Temperance is the best physic.

That is well spoken that is well taken.

That penny is well spent that saves a groat.

That's placing the cart before the horse.

That was laid on with a trowel.

The absent party is still faulty.

The ass that brays most eats least.

The best physicians are Dr Diet, Dr Quiet, and Dr Merryman.

The better day the better deed.

The blind man's wife needs no painting.

The cobbler's wife is the worst shod.

The comforter's head never aches.

The covetous man is his own tormentor.

The crow thinks her own bird the fairest.

The devil is not as black as he is painted.

The devil was sick, the devil a monk would be;

The devil grew well, the devil a monk was he.

The end of a feast is better than the beginning of a fray.

The eye of the master does more work than both his hands.

The farthest way about is often the nearest way home.

The faulty stands on his guard.

The foremost dog catches the hare.

The galled jade will wince.

The goodness of a pudding is known in the eating.

The grey mare is the better horse.

The greatest burdens are not the gainfullest.

The greatest strokes make not the best music.

The greatest wealth is contentment with little.

The groat is ill saved that shames the master.

The guilty mind needs no accuser.

The handsomest flower is not the sweetest.

The hasty hand catches frogs for fish.

The hastiest man that is must wait while his drink is drawing.

The highway is never about.

The highest branch is not the safest roost.

The hotter war the sooner peace.

The last drop makes the cup run over.

The last suitor wins the maid.

The lion's skin is never cheap.

The longest day must have an end.

The market is the best garden.

The married man must turn his staff into a stake.

The mill cannot grind with the water that is past.

The mob has many heads but no brains.

The more noble the more humble.

The more the merrier, the fewer the better cheer.

The more you heap, the worse you cheap.

The nearer the church the farther from God.

The offender never pardons.

The path of virtue is the path of peace.

The rat which has but one hole is soon caught.
 The receiver is as bad as the thief.
 The still sow sucks the most wash.
 The sweetest wine makes the sharpest vinegar.
 There is a tide in the affairs of men, which taken at
 the flood leads on to fortune.
 There is luck in leisure.
 There is reason in roasting eggs.
 There's a salve for every sore.
 There's no compassion like the penny.
 There's no fool like an old fool.
 There's no general rule without an exception.
 There's no joy without alloy.
 The table robs more than the thief.
 The truest jests sound worst in guilty ears.
 The truth may be blamed but not shamed.
 The weakest must go to the wall.
 The wearer best knows where the shoe pinches him.
 There would be no ill language if it were not ill
 taken.
 There would not be great ones if there were no little.
 They love too much that die for love.
 They must hunger in frost, that will not work in
 heat.
 They need much whom nothing will content.
 Think of ease, but work on.
 Those who live longest will see most.
 Those who play with edge tools must expect to be cut.
 Threatened folks live long.
 Time and tide stay for no man.
 Time is a file that wears and makes no noise.
 Timely blossom, timely fruit.
 'Tis the second blow that makes the fray.
 To a child all weather is cold.
 To a crazy ship all winds are contrary.
 To be hail fellow well met with one. [In good fellow-
 ship].
 To be in a merry pin.
 To dine with Duke Humphry. [To go without dinner].
 To err is human, to forgive divine.
 To find a mare's nest. [To discover something already
 well known].
 To give and keep there is need of wit.
 To go through thick and thin. [Stick at nothing.]
 To go to pot.
 To have nothing but one's labour for one's pains.
 To have the law in one's own hand.
 To have two strings to one's bow.
 To kill two birds with one stone.
 To laugh in one's sleeve.
 To leave a morsel for the Duke of Rutland. [That is—
 to leave it for the sake of *manners*, *Manners* being
 the family surname of the Duke of Rutland.]
 Too many cooks spoil the broth.
 Too much familiarity breeds contempt.
 To play the dog in the manger. [Not to eat yourself
 nor let any body else.]
 To put one's nose out of joint.
 To rob Peter to pay Paul.
 To seek a needle in a bundle of hay.
 To send one away with a flea in his ear [in a state of
 trepidation and astonishment.]
 To set up one's staff of rest [to propose to abide in a
 place.]
 To stand in one's own light.
 To starve in a cook-shop.
 To strain at a gnat and swallow a camel.
 To take a wrong sow by the ear.
 To tell tales out of school.
 To throw the helve after the hatchet [giving up a
 thing in despair.]
 To twist a rope of sand.
 Trade is the mother of money.
 Tread on a worm and it will turn.
 Trim-tram—like master, like man.
 True praise takes root and spreads.
 Truth hath always a fast bottom.
 Two heads are better than one.
 Two of a trade seldom agree.

Two swallows do not make a summer.

Unknown, unmissed.

Unminded, unmoved.

Use the means, and God will give the blessing.

Valour is worth little without discretion.

Valour that parleys is near yielding.

Venture a small fish to catch a great one.

Venture not all in one bottom.

War is death's feast.

Waste not, want not.

Wealth makes worship.

Welcome is the best cheer.

We must eat a peck of salt with a man before we
 know him.

We never know the worth of water till the well is dry.
 What cannot be cured must be endured.

What is bred in the bone will not come out of the
 flesh.

What is got over the devil's back is spent under his
 belly.

What the eye sees not the heart rues not.

What the goodwife spares, the cat eats.

When a dog is drowning, every one offers him water.

When all is consumed, repentance comes too late.

When fortune smiles on thee, take the advantage.

When many strike on an anvil, they strike by measure.

When poverty comes in at the door, love flies out at
 the window.

When rogues fall out, honest men get their own.

When sorrow is asleep, wake it not.

When the cat's away, the mice play.

When the Goodman's from home, the goodwife's table
 is soon spread.

When wine's in wit's out.

When two Sundays meet. [Never.]

When you are at Rome, do as they do at Rome.

When we have gold we are in fear, when we have
 none we are in danger.

When drink enters, wisdom departs.

Where much smoke is, there must be some fire.

Where the carcass is, there the ravens will collect
 together.

Where the king is, there is the court.

Where the will is ready the feet are light.

Where there is a will there is always a way.

Write injuries in dust, but kindnesses in marble.

While the grass grows the cow starves.

While there's life there's hope.

Who dainties love shall beggars prove.

Who loathes his due getteth no thanks.

Who perisheth in needless danger is the devil's martyr.

Who spends more than he should, shall not have to
 spend when he would.

Who spits against the wind spits in his own face.

Wide will wear, but narrow will tear.

Wilful waste makes woful want.

Wise men care not for what they cannot have.

Wisely and slow: they stumble who run fast.

Wool sellers know wool buyers.

Words may pass, but blows fall heavy.

Wranglers never want words.

York—every man pay his share.

You are busy as a hen with one chick.

You come like a godfather after the christening.

You can look at teeth and not be bitten.

You can't see green cheese but your teeth must water.

You cannot catch old birds with chaff.

You cannot eat your cake and have it also.

You cannot have blood out of a stone.

You cannot hide an eel in a sack.

You cannot kill a dog with a bone.

You cannot make a silk purse out of a sow's ear.

You cannot wash the blackamore white.

You need not grease a fat sow.

You taste the broth soon as the meat is put in.

SCOTS PROVERBS.

A begun turn is half ended.
 A bit is often better gi'en than eaten.
 A blate cat maks a proud mouse.
 A black hen lays a white egg.
 A borrowed len' should gae laughing hame.
 A fidging mare should be weel girded.
 Affront your friend in daffin', and time him in earnest.
 A fou man and a hungry horse aye mak haste hame.
 A friend's dinner's soon dished.
 Aft ettie, whiles hit.
 After a storm comes a calm.
 A gi'en horse shouldna be looked i' the mouth.
 A gi'en piece is soon eaten.
 A greedy e'e ne'er gat a gude pennyworth.
 A green Yule maks a fat kirk-yard.
 A gude cause maks a strong arm.
 A handfu' o' trade is worth a gowpen o' gowd.
 A hantle cry murder, yet are aye uppermost.
 A hasty man never wanted wae.
 A hunger and a burst.
 A kiss and a drink o' water mak but a poor breakfast.
 A man's weel or wae as he thinks himsel sae.
 Ane cannot wive and thrive baith in ae year.
 Ane may lo'e a haggis, that wadna hae the bag thrown in his teeth.
 Ane ne'er tines by doing gude.
 An ilka-day braw makes a sabbath-day daw.
 An ill shearer never got a gude heuk.
 An ill wife and a new-kindled candle should hae their heads hadden down.
 An inch o' gude fortune is worth a fathom o' forecast.
 An inch o' a miss is as gude as a span.
 A nod o' honest men is enugh.
 A pund o' care winna pay an ounce o' debt.
 A rough bane makes a fou wame.
 As dark as a Yule midnight.
 As gude fish in the sea as e'er came out o't.
 As gude may haud the stirrup as he that loup on.
 A Scotch mist will wet an Englishman to the skin.
 A sillerless man gangs fast through the market.
 A sorrowfu' heart is aye dry.
 A' Stewarts are no sib to the king.
 A tale never tines in the telling.
 A tarrowing hen was never fat.
 A tocherless dame sits lang at hame.
 At open doors dogs gae ben.
 A wee mouse can creep under a great corn stack.
 A wee thing puts your beard in a bleeze.
 A wight man ne'er wanted a weapon.
 A wilfu' man should be unco wise.
 Auld men are twice bairns.
 Auld sparrows are ill to tame.
 Auld springs gie nae price.

Bairns speak in the field what they hear in the ha'.
 Bargain is bargain.
 Be a friend to yoursel, and others will.
 Bear and forbear is gude philosophy.
 Bear wealth weel, poortith will bear itsel.
 Be aye the same thing you would be ca'd.
 Be lang sick that ye may be soon hale.
 Best to be off with the old love before we be on with the new.
 Be thou weel, be thou wae, thou wilt not be aye sae.
 Better a bit in the morning than fast a' day.
 Better a finger off than aye wagging.
 Better a tocher in her than on her.
 Better a toom house than an ill tenant.
 Better a wee bush than nae bield.
 Better a wee fire to warm you than a big fire to burn you.
 Better be blithe wi' little than sad wi' naething.
 Better buy than borrow.
 Better lang something than soon naething.
 Better skaith saved than mends made.
 Better sma' fish than nane.

Better to haud than draw.
 Better wear shoon than wear sheets.
 Blind men shouldna judge o' colours.
 Bode for a silk gown and ye'll get a sleeve o't.
 Broken bread makes hale bairns.
 Burning a halfpenny candle seeking a farthing.
 Burnt bairns dread the fire.
 By chance a cripple may catch a hare.

Cadgers have aye mind of lade saddles.
 Canny stretch, soon reach.
 Carrying saut to Dysart.
 Cast a bane in a deil's teeth.
 Cast not a clout till May be out.
 Castna out the dowed water till ye get the fresh.
 Cauld cools the love that kindles ower het.
 Change your friend ere you hae need.
 Cheatey kythes.
 Cleanliness is nae pride, dirt's nae honesty.
 Come unca'd sits unserved.
 Come wi' the wind and gang wi' the water.
 Confess and be hanged.
 Confess debt and crave days.
 Corn him weel, he'll work the better.
 Count again is not forbidden.
 Count siller after a' your kin.
 Courtesy is cumbersome to him that kens it na.
 Covetousness brings naething hame.
 Craft maun hae claes, but truth gaes naked.
 Credit is better than ill luck.
 Credit is better than ill-won gear.
 Credit keeps the crown o' the causey.
 Credit lost is like a broken glass.

Daffin and want o' wit maks auld wives donart.
 Dame, deem warily, ye watna wha wytes yoursel.
 Daming and laving is good sure fishing.
 Daughters and dead fish are nae keeping ware.
 Dawted bairns dow bear little.
 Daylight will peep through a sma' hole.
 Deal sma' an' serve a'.
 Death and marriage break term-day.
 Death at ae door and hardship at the other.
 Deil be in the house that ye're beguiled in.
 Deil stick pride, for my dog died o't.
 Ding down the nest, and the rooks will flee away.
 Dinna cast awa' the cog when the cow flings.
 Dirt bodes luck.
 Dinna gut your fish till ye get them.
 Do as the lasses do, say-Na, an' tak it.
 Dogs bark as they are bred.
 Dogs an' bairns are aye fond o' fools.
 Do not meddle wi' the deil an' the laird's bairns.
 Do not touch him on the sair heel.
 Dool an' ill life soon mak an auld wife.
 Double drinks are aye guid for drowth.
 Do weel an' doubt nae man, do ill an' doubt a' men.
 Do weel an' hae weel.
 Dows an' dominies leave aye a foul house.
 Do your turn weel, an' nane will speer what time ye took.
 Draff he sought, but drink was his errand.
 Dree out the inch when ye hae thoged the span.
 Drink an' drowth come nae aye thegither.
 Drink little that ye may drink lang.
 Drive a cow to the ha', she'll run to the byre.

Early birds catch the worms.
 Early master, soon knave.
 East or west, hame is best.
 Easy learned, soon forgotten.
 Easy learning the cat the road to the kirn.
 Easy to that thy ain heart wills.
 Easily working when will's at hame.
 Eat in measure, an' defy the doctor.
 Eat peas wi' a prince, an' cherries wi' a chapman.
 Eat-weel's Drink-weel's brither.
 Eating an' cleaning only require a beginning.
 Eating an' drinking puts awa the stomach.

Ell and tell is gude merchandise.
 Envy is the rack of the soul and torture of the body.
 Envy ne'er does a gude turn but when it means an ill
 ane.
 Even as you won it say may you wear't.
 Ever busy ever bare.
 Every ane loup the dike where it's laigest.
 Every ane to his trade, quoth the browster to the
 bishop.
 Every bird thinks its ain nest best.
 Every cock craws crousest on his ain midden head.
 Every day's no Yule-day—cast the cat a castock.
 Every fault has its fore.
 Every flow has its ebb.
 Every inch of joy has an ell of annoy.
 Every man bows to the bush he gets bield frae.
 Every man buckles his belt his ain gate.
 Every man can guide an ill wife weel but him that has
 her.
 Every man can tout best on his ain horn.
 Every man has his ain draff pock.
 Every man's tale's gude till anither's be tauld.
 Every May be hath a May not be.
 Every miller wad weise the water to his ain mill.
 Every play maun be played, an' some maun be the
 players.
 Fair words break nae banes, foul words mony.
 Fancy flees before the wind.
 Far-awa fowls hae fair feathers.
 Farther east the shorter west.
 Fause folk should hae mony witnesses.
 Faushood makes ne'er a fair hinder-end.
 Favour unused is favour abused.
 Fill fu' an' haud fu', that makes a man stark.
 Flaes an' a girning wife are waukrife bed-fellows.
 Flee ne'er so fast, your fortune will be at your tail.
 Fleeing a bird is no the way to grip it.
 Fling-at-the-goad was ne'er a gude ox.
 Flitting o' farms mak mailens dear.
 Fools are aye fond o' flittin'.
 Fools are aye seeing ferlies.
 Fool's haste is nae speed.
 Fools laugh at their ain sport.
 Fools set far trysts.
 Fools shouldna hae chappin'-sticks.
 For fashion's sake, as dogs gang to the market.
 For want o' a steek a shoe may be tint.
 Forbid a fool a thing, an' that he will do.
 Frae saving comes having.
 Fresh fish an' poor friends grow soon ill-faured.
 Friends are like fiddle-strings, they maunna be screwed
 ower tight.
 Friends gree best at a distance.
 Friendship canna stand aye on ae side.
 Fry stanes wi' butter, an' the broe will be gude.
 Gathering gear is a pleasant pain.
 Gaily wad be better.
 Gear is easier gotten than guided.
 Gentle partans hae lang taes.
 Gentle servants are poor men's tinsel.
 Get weel, keep weel.
 Gie a bairn its will an' a whelp its fill, and neither will
 do weel.
 Gie your tongue mair holidays than your head.
 Giff-gaff maks gude friends.
 Glasses an' lasses are brittle ware.
 Glowering's nae gainsaying.
 God ne'er sent the mouth, but he sent the meat wi't.
 God send water to that well that folk think will ne'er
 rin dry.
 God shapes the back for the burden.
 Good wine makes a bad head and a lang story.
 Gratitude is a heavy burden.
 Great comfort is like ready gold in need.
 Greedy folks hae lang arms.
 Griening wives are aye greedy.
 Guessed wark's best if weel done.

Gude advice is ne'er out o' season.
 Gude ale needs nae wisp.
 Gude bairns are eith to lear.
 Gude breeding and siller mak our sons gentlemen.
 Gude claes open a' doors.
 Gude company on a journey is worth a coach.
 Gude gear's not to be gapped.
 Gude fishing in drumly water.
 Gude folk are scarce, tak care o' ane.
 Gude forecast farthers the wark.
 Gude health is better than wealth.
 Gude kail is half meat.
 Gude watch prevents harm.
 Gude will ne'er wants time to show itsel.
 Gude will should be ta'en in part payment.
 Gudely cow, gawsy calf.
 Hae, gars a deaf man hear.
 Hand-in-use is father o' lear.
 Hang a thief when he's young, an' he'll no steal when
 he's auld.
 Hang hunger an' drown drouth.
 Hanking an' hingin-on is a poor trade.
 Happy the wife that's married to a motherless son.
 He can hide his meat and seek mair.
 He can say Jo, and think it no.
 He can see an inch before his nose.
 He cares na wha's bairns greet if his laugh.
 He comes oftener wi' the rake than the shool.
 He complains early that complains o' his kail.
 He doesna ken what end o' him's uppermost.
 He doesna aye ride when he saddles.
 He doesna like his wark that says *now* when its done.
 He eats the calf i' the cow's wame.
 He gangs awa in an ill time that ne'er comes again.
 He gangs lang barefoot that wears dead men's shoon.
 He girns like a sheep-head in a pair o' tangs.
 He has a caup for a' corn.
 He has a gude judgment that doesna lippen to his
 ain.
 He has a hearty hand for gieing a hungry mealtith.
 He has a slid grip that has an eel by the tail.
 He has been rowed in his mither's sark tail.
 He has brought his pock to a braw market.
 He has come to gude by misguiding.
 He has coosten his cloak on his ither shoulder.
 He has coupit the meikle pot into the little.
 He has faut o' a wife that marries mam's pet.
 He has feathered his nest, he may flee when he likes.
 He has gotten the whip hand of him.
 He has lain on his wrang side.
 He has licked the butter aff my bread.
 He has mair wit in his little finger than ye hae in a'
 your bouk.
 He has muckle prayer but little devotion.
 He has some wit, but a fool has the grinding o't.
 He has the best end of the string.
 He has wit at will that wi' an angry heart can sit
 still.
 He has't o' kind, he coft it not.
 He hears wi' his heel, as geese do in harvest.
 He kens his ain groats amang ither folk's kail.
 He kens whilk side his cake is buttered on.
 He'll gie you the whistle o' your groat.
 He'll have enugh some day, when his mouth's fu' o'
 mools.
 He'll mak an ill runner that canna gang.
 He'll mend when he grows better, like sour ale in
 summer.
 He'll neither dance nor haud the candle.
 He'll no gie an inch o' his will for a span o' his thrift.
 He'll no let grass grow at his heels.
 He'll no sell his hen on a rainy day.
 He'll soon be a beggar that canna say no.
 He'll tell it to nae mair than he meets.
 He lo'ed mutton weel that licked where the ewe lay.
 He lo'es me for little that hates me for nought.
 He looks like the far end of a French fiddle.
 He maun be soon up that cheats the tod.

PROVERBS AND OLD SAYINGS.

He maun hae leave to speak that canna haud his tongue.
 He may find fault that canna mend.
 He needs a lang spoon that sups wi' the deil.
 He ne'er did a gude darg that gaed grumbling about it.
 He reads his sin in his punishment.
 He rides sicker that never fa's.
 He's a fool that forgets himsel.
 He's a fool that marries at Yule; for when the bairn's to bear, the corn's to shear.
 He's a hawk of a right nest.
 He's a man of a wise mind, that of a foe can mak a friend.
 He's a proud cook that maunna lick his ain fingers.
 He's a proud fox that winna scrape his ain hole.
 He's a silly chiel that can neither do nor say.
 He's a worthless guidman that's no miss'd.
 He's as welcome as water in a riven ship.
 He's horn deaf on that side o' the head.
 He should sit close that has riven breeks.
 He sleeps as dogs do when wives sift meal.
 He's like a flae in a blanket.
 He's like the singet cat, better than he's likely.
 He's no the best wright that casts maist spails.
 He's no sae daft as he lets on.
 He's ower soon up that's hanged e'er noon.
 He's poor enough that's ill lo'd.
 He's sairest dung that's paid wi' his ain wand.
 He starts at straes, and lets windlins gae.
 He's the gear that winna traik.
 He's unco fu' in his ain house that canna pick a bane in his neighbour's.
 He's weel worthy o' sorrow that buys it.
 He's weel boden there ben, that will neither borrow nor len'.
 He's wise that's timely wary.
 He's worth nae weel that can bide nae wae.
 He that blows best let him beat the horn.
 He that buys nuts buys shells, but he that buys gude ale buys naething else.
 He that canna mak sport should mar nane.
 He that cheats me ance, shame fa' him; if he cheat me twice, shame fa' me.
 He that counts a' costs will ne'er put plough i' the grund.
 He that deals in dirt has aye foul fingers.
 He that does you an ill turn will ne'er forgie you.
 He that forecasts a' perils will win nae worship.
 He that fa's in a gutter, the langer he lies the dirtier he is.
 He that fishes before the net, fishes lang or he fish get.
 He that gets forgets, but he that wants thinks on.
 He that gets gear before he gets wit, will die e'er he thrive.
 He that has a mickle nose thinks ilk ane speaks o't.
 He that has but ae e'e maun tent that weel.
 He that has mickle wad aye hae mair.
 He that has nae gear to time may hae shins to pine.
 He that has twa hoards will get a third.
 He that keeks through a hole may see what will vex him.
 He that lends his pot may seethe his kail in his loof.
 He that looks to freets, freets will follow him.
 He that rides or he be ready, wants aye some o' his graith.
 He that's aught the cow gangs nearest the tail.
 He that's ill to himsel will be gude to naeboddy.
 He that seeks motes gets motes.
 He that shows his purse bribes the thief.
 He that speers all opinions comes ill speed.
 He that steals can hide too.
 He that tholes overcomes.
 He that will cheat in play winna be honest in earnest.
 He that will not thole maun flit mony a hole.
 He that will to Cupar maun to Cupar.
 He that winna when he may, shanna when he wad.
 He that would eat the kirkel maun crack the nut.
 He wad gang a mile to flit a sow.

He wad gar you trow that the moon's made o' green cheese.
 He wad tine his lugs if they were not tacked to him.
 He was mair fleyed than hurt.
 He was scant o' news that tauld his father was hanged.
 He was the bee that made the honey.
 He winna send you awa' wi' a sair hairt.
 Highlanders—shoulder to shoulder.
 I canna sell the cow an' sup the milk.
 I hae mair to do than a dish to wash.
 I ken by my cog my cow's milked.
 If ae sheep loup the dyke, a' the rest will follow.
 If the deil be laird, ye'll be tenant.
 If the deil find you idle, he'll set you to wark.
 If the lift fa', the laverocks will be smooed.
 If you win at that, you'll lose at naething.
 If ye sell your purse to your wife, gie her your breeks to the bargain.
 Ill bairns are aye best heard at hame.
 Ill bairns aye get broken brows.
 Ill beef ne'er made gude broe.
 Ill comes upon waur's back.
 Ill counsel will gar a man stick his ain mare.
 Ill doers are aye ill dreaders.
 Ill getting het water frae 'neath cauld ice.
 Ill hearing maks wrang rehearsing.
 Ill herds mak fat foxes.
 Ill laying up maks mony thieves.
 Ill payers are aye gude cravers.
 Ill will ne'er spak weel.
 Ill-won gear winna enrich the third heir.
 Ill workers are aye gude onlookers.
 I'll ne'er brew drink to treat drunkards.
 I'll ne'er keep a cow when I can get milk sae cheap.
 I'll ne'er keep a dog and bark mysel.
 I'll ne'er lout sae laigh and lift sae little.
 I'll ne'er put the rogue aboon the gentleman.
 I'll rather strive wi' the lang rigg than the ill neighbour.
 I'll serve ye when ye hae least to do.
 I'll tak the best first, as the priest did o' the plums.
 I might bring a better speaker frae hame than you.
 I'm no every man's dog that whistles on me.
 I'm no obliged to summer an' winter it wi' you.
 I'm no sae blind as I'm bleer-eyed.
 I'm no sae scant o' clean pipes as to blaw wi' a brunt cutty.
 I'm o'er auld a cat to draw a strae before.
 I'm speaking o' hay and you o' horse corn.
 I ne'er sat on your coat-tail.
 I think mair o' your kindness than its a' worth.
 It maun be true what a' folk says.
 It's a far cry to Lochaw.
 It's a hard task to be poor and leal.
 It's a mean mouse that has but ae hole.
 It's a nasty bird that files its ain nest.
 It's a silly hen that canna scrape for ae bird.
 It's an ill pack that's no worth the custom.
 It's better to sup wi' a cutty than want a spoon.
 It's by the head that the cow gies milk.
 It's far to seek an' ill to find.
 It's gude baking beside the meal.
 It's gude sleeping in a hale skin.
 It's gude to be sib to siller.
 It's gude gear that pleases the merchant.
 It's gude to be in your time, ye kenna how lang it may last.
 It's gude to dread the warst, the best will be the welcomer.
 It's hard both to have and want.
 It's hard for a greedy e'e to hae a leal heart.
 It's hard to sit in Rome an' strive wi' the pope.
 It's ill bringing butt what's no ben.
 It's ill speaking between a fu' man and a fasting.
 It's ill wared that wasters want.
 It's kittle for the cheeks when the hurlbarrow gae's o'er the brig o' the nose.

It's kittle shooting at corbies and clergy.
 It's kittle to waken sleeping dogs.
 It's lang before the deil be found dead at the dyke-side.
 It's lang ere the deil dee.
 It's nae laughing to girn in a widdy.
 It's nae play when ane laughs and anither greets.
 It's needless to pour water on a drowned mouse.
 It's no lost what a friend gets.
 It's not what is she but what has she.
 Its ower far between the kitchen an' the ha'.
 It's ower late to spare when the back's bare.
 It's past jouking when the head's aff.
 It's stinking praise comes out o' ane's ain mouth.
 It's the best spoke in your wheel.
 It's well that our faults are not written in our face.
 It was never for naething that the gleg whistled.
 It will be feathered out o' your wing.
 It will be lang ere ye wear to the knee lids.
 I wad be scant o' claith to sole my hose wi' dockens.
 I would rather see't than hear tell o't.
 I wadna be deaved wi' ye're keeking for a' your eggs.
 I wadna ca' the king my cousin.
 I wish you readier meat than a rinnin hare.

Joke at leisure, you kenna wha may jibe yoursel.
 Jouk and let the jaw gang by.

Keep out o' his company that cracks o' his cheatery.
 Keep something for a sore foot.
 Keep the feast till the feast day.
 Keep the staff in your ain hand.
 Keep your ain fish guts to your ain sea-maws.
 Keep your breath to cool your own porridge.
 Keep your mouth shut and your e'en open.
 Ken when to spend and when to spare, and ye needna be busy, and ye'll ne'er be bare.
 Ken yoursel, and your neighbour winna misken you.
 Kend folk's nae company.
 Kings and bears aft worry their keepers.
 Kings' chaff's worth other folk's corn.
 Kings' cheese gaes half away in parings.
 Kings hae lang hands.
 Kindle a candle at baith ends, it will soon be done.
 Kindness comes o' will, it canna be coft.
 Kindness will creep where it canna gang.
 Kiss a carle and clap a carle, that's the way to tine a carle.
 Kythe in your ain colours, that folk may ken you.

Laith to bed and laith to rise.
 Lang fasting gathers wind.
 Lang fasting hains nae meat.
 Lang standing and little offering maks a poor priest.
 Lang straes are nae notes.
 Laugh at leisure, ye may greet ere night.
 Law's costly, tak a pint and gree.
 Law makers shouldna be law breakers.
 Lay the head o' the sow to the tail o' the grice.
 Lay your wame to your winning.
 Leal heart never lied.
 Learn the cat the road to the kirn, and she'll aye be lickin.
 Learn you to an ill habit, and ye'll ca't custom.
 Learn young, learn fair.
 Let a' trades live, quoth the wife, when she brunt her besom.
 Let alane, maks mony a loon.
 Let byganes be byganes.
 Let him cool in the skin he het in.
 Let him tak a spring on his ain fiddle.
 Let his ain wand ding him.
 Let ilka ane soop before their ain door.
 Let ilka sheep hang by its ain shank.
 Let na the plough stand to kill a mouse.
 Let the horns gang wi' the hide.
 Let the mickle horse get the mickle windlin.
 Let the tow gang wi' the bucket.
 Let them care that come behind.

Let your meat dit your mouth.
 Light burdens break nae banes.
 Like a cow on an unco loan.
 Like a sow playing on a trumpe.
 Like butter in the black dog's house.
 Like hens, ye rin aye to the heap.
 Like the bairns o' Falkirk, ye mind naething but mischief.
 Like the cat, fain fish wad ye eat, but ye are laith to weet your feet.
 Like the wife that aye took what she had, and never wanted.
 Like the wife that ne'er cries for the ladle till the pot rins o'er.
 Like the wife wi' the mony daughters, the best comes hindmost.
 Like's an ill mark.
 Lippen to me, but look to yoursel.
 List to meat's gude kitchen.*
 Little dogs hae lang tails.
 Little folk are soon angry.
 Little Jock gets the little dish, and that hauds him lang little.
 Little kenne'd, the less cared for.
 Little meddling maks fair parting.
 Little wats the ill-willy wife what a dinner may haud in.
 Little wit in the head maks mickle travel to the feet.
 Little mense to the cheeks to bite aff the nose.
 Living at heck and manger.
 Lock your door, that you may keep your neighbours honest.
 Lo'e me little, an' lo'e me lang.
 Love and lairdships like nae marrows [equals.]
 Love is as warm among cottars as courtiers.
 Love owerlooks mony faults.
 Maidens should be mild and meek, quick to hear and slow to speak.
 Mair by luck than gude guiding.
 Mair haste the waur speed, quoth the tailor to the lang thread.
 Mair than enough is ower mickle.
 Mak a kirk an' a mill o't.
 Mak nae toom ruse.
 Malice is aye mindfu'.
 Marriage and hanging go by destiny.
 Marry a beggar, and get a louse for your tocher.
 Marry aboon your match, and get a master.
 Marry for love, and work for siller.
 Master's will is gude wark.
 Mastery maws the meadows down.
 Maun-do is a fell fallow.
 May-be's are no aye honey-bees.
 Measure twice, cut but ance.
 Meat feeds, claith cleads, but manners mak the man.
 Mickle musing mars the memory.
 Mickle power maks mony faes.
 Mickle about ane, quoth the deil to the collier.
 Mickle gifts mak beggars bauld.
 Mickle head, little wit.
 Mickle maun a gude heart thole.
 Mickle meat, mony maladies.
 Mess and meat ne'er hinder'd wark.
 Mettle's dangerous in a blind mare.
 Money is like the muck midden, it does nae gude till it be spread.
 Money is welcome any way.
 Money maks a man free ilka where.
 Mony an honest man needs help that hasna the face to seek it.
 Mony ane kisses the bairn for love o' the nurse.
 Mony ane lacks what they would fain hae in their pack.
 Mony ane serves a thankless master.
 Mony ane speers the gate they ken fu' weel.
 Mony ane's gear is mony ane's death.
 Mony gude-nights is laith away.

* Hunger is the best sauce.

PROVERBS AND OLD SAYINGS.

Mony kinsfolk, but few friends.
 Mony littles mak a mickle.
 Mony purses haud friends lang thegither.
 Mony ways to kill a dog, though ye dinna hang him.
 Mony wyte their wife for their ain thriftless life.

Nae fleeing without wings.
 Nae man can live langer in peace than his neighbours like.

Nae man can mak his ain hap.
 Nae man has a tack o' his life.
 Nae wonder to see wasters want.
 Naething but fill and fetch mair.
 Naething is a man's truly but what he comes by duly.
 Naething is got without pains but dirt and lang nails.
 Naething is sae difficult but we may owercome by perseverance.

Naething sae bauld as a blind mare.
 Naething to be done in haste but gripping flaes.
 Naething to do but draw in your stool and sit down.
 Nane are sae weel but they hope to be better.
 Nane can play the fool sae weel as a wise man.
 Need maks greed.
 Need will gar an auld wife trot, and a naked man rin.
 Ne'er draw your dirk when a dunt will do.
 Ne'er fash your thoom.
 Ne'er let on, but laugh in your ain sleeve.
 Ne'er lippen owre mickle to a new friend or an auld enemy.

Ne'er marry a widow unless her first man was hanged.
 Ne'er owre auld to learn.
 Ne'er put a sword in a madman's hand.
 Ne'er put the plough before the owsen.
 Ne'er put your hand farther out than your sleeve will reach.

Ne'er rax aboon your reach.
 Ne'er sca'd your lips in ither folk's kail.
 Ne'er seek a wife till ye ken what to do wi' her.
 Ne'er shaw me the meat but the man.
 Ne'er shaw your teeth unless ye can bite.
 Ne'er speak ill o' them whase bread ye eat.
 Ne'er strive against the stream.
 Ne'er tak a forehammer to break an egg.
 Ne'er tell your fae when your foot sleeps.
 Neither to haud nor to bind.
 Neither sae sinfu' as to sink nor sae haly as to swim.
 Next to nae wife, a gude wife is the best.
 Nobility without ability is like a pudding without suet.

O' a' sorrow, a fu' sorrow's the best.
 Owre braw a purse to put a plack in.
 Owre reckless may repent.
 Owre sicker, owre loose.
 Owre strong meat for your weak stamach.
 Of a' flatterers, self-love is the greatest.
 Of ae ill comes mony.
 Of ill debtors men get aiths.
 Ony thing for you about an honest man's house but a day's wark.
 Open confession is gude for the soul.
 Our sins and debts are aften mair than we think.
 Out o' the peat pot into the gutter.
 Owre mony grieves only hinder the wark.

Pay him in his ain coin.
 Placks and bawbees grow pounds.
 Play's good while it's play.
 Please your kimmer, and you'll easily guide your gos-sip.
 Plenty maks dainty.
 Poor folk's friends soon misken them.
 Poverty is the mother o' a' arts.
 Pride and grace ne'er dwell in ae place.
 Pride finds nae cauld.
 Pride ne'er leaves its master till he get a fa'.
 Pride that dines wi' vanity sups wi' contempt.
 Provision in season makes a bein house.
 Put a coward to his metal and he'll fight the deil.
 Put on your spurs and be at your speed.

Put twa pennies in a purse and they'll creep thegither.
 Put your finger in the fire, and say it was your fortune.
 Put your hand twice to your bonnet for ance to your pouch.

Quality without quantity is little thought of.
 Quey calves are dear veal.
 Quick, for you'll ne'er be cleanly.
 Quietness is best.

Rather spoil your joke than tane your friend.
 Raw dads mak fat lads.
 Raw leather raxes weel.
 Reckon up your winning at your bed-stock.
 Red wood maks good spindles.
 Reputation is aften got without merit and lost without crime.
 Rich folk hae routh o' friends.
 Rich mixture maks gude mortar.
 Riches are got wi' pain, kept wi' care, and tint wi' grief.
 Ride fair, and jap nane.
 Right wrangs nae man.
 Rob Gib's contract—stark love and kindness.
 Roose the fair day at e'en.
 Rue and thyme grow baith in ae garden.
 Rule youth weel, for eild will rule itsel.

Saut, quoth the souter, when he had eaten a cow a' but the tail.
 Saw thin, shear thin.
 Say still No, and ye'll ne'er be married.
 Scanty cheeks mak a lang nose.
 Scart-the-cog wad sup mair.
 Send your gentile bluid to the market, and see what it will buy.
 Serve yoursel till your bairns come of age.
 Set a stout heart to a stey brae.
 Shame fa' them that think shame to do themselves a gude turn.
 She brak her elbow at the kirk door.
 She hauds up her head like a hen drinking water.
 She looks as if butter wadna melt in her mouth.
 She looks like a lady in a landward kirk.
 She that gangs to the well wi' an ill will, either the pig breaks or the water will spill.
 She'll keep her ain side o' the house, and gang up and down yours.
 She'll wear like a horse-shoe, aye the langer the clearer.

She's better than she's bonny.
 Show me the man, and I'll show you the law.
 Sic as ye gie, sic will ye get.
 Silence grips the mouse.
 Slander leaves a sair behind.
 Smooth waters run deep.
 Soon enough if weel enough.
 Soon enough to cry Chuck, when it's out o' the shell.
 Sorrow and ill weather come unsent for.
 Sorrow is soon enough when it comes.
 Speak good of pipers, your father was a fiddler.
 Spilt ale is waur than water.
 Stay nae langer in a friend's house than you're welcome.
 Stuffing hauds out storming.

Tak a man by his word and a cow by her horn.
 Tak the bit and the buffet wi't.
 Tak time ere time be tint.
 Tak wit i' your anger.
 Tak your ain will, and ye'll no die o' the pet.
 Tak your thanks to feed your cat.
 Tak your venture, as mony a gude ship has done.
 That's Halkerston's cow.*
 The black ox ne'er trod on his foot.†

* A story told the reverse of the real occurrences.

† Death never gave him sorrow.

The book o' maybes is very braid.
 The cost owergangs the profit.
 The deil aye drives his hogs to an ill market.
 The deil doesna aye show his cloven cloots.
 The deil gaes awa when he finds the door steekit
 against him.
 The deil's bairns have aye their daddy's luck.
 The deil's aye gude to his ain.
 The deil's gane ower Jock Wabster.*
 The deil will tak little ere he want a'.
 The deil's aye busy wi' his ain.
 The first fuf o' a fat haggis is the bauldest.
 The foot at the cradle and the hand at the reel, is a
 sign that a woman means to do weel.
 The grace o' a grey bannock's in the baking o't.
 The head for the washing.
 The higher the hill the laigher the grass.
 The hurt man writes wi' steel on marble stane.
 The king may come in the cadger's gate.
 The kirk's mickle, but you may say mass in the end
 o't.
 The laird may be laird, and yet need his hind's help.
 The master's foot's the best measure.
 The o'ercome only fashes folk to keep.
 There is an act in the Laird o' Grant's court, that no
 aboon eleven speak at ance.
 There was a wife that kept her supper for her break-
 fast, and she was dead ere day.
 There was ne'er a gude town but there was a dub at
 the end o't.
 There was never a silly Jocky but there was as silly
 a Jenny.
 There was ne'er a thrifty wife wi' a sheet about her
 head.
 There's a dub before every door.
 There's a tough sinew in an auld wife's heel.
 There's a whaup i' the raip.†
 There's aye some water where the stirkie drowns.
 There's beild aneath an auld man's beard.
 There's steel in the needle point, though little o't.
 There's the end o' an auld sang.
 The simple man's the beggar's brither.
 The smith's mare and the souter's wife are aye the
 warst shod.
 The tod ne'er sped better than when he gaed his ain
 errand.
 The thing that lies na in your gate breaks na your
 shins.
 The thrift o' you and the woo o' a dog wad mak a
 brow web.
 The worth o' a thing is best kenned by the want o't.
 The wife's aye welcome that comes wi' a crooked
 oxters.‡
 They'll gree better when they gang in by different
 kirk doors.
 They that board wi' cats maun count upon scarts.
 They that burn you for a witch lose a' their coals.
 They that gie you hinder you to buy.
 They that lie down for love should rise up for hunger.
 They that love maist speak least.
 They were scant o' bairns that brought you up.
 They are sad rents that come in wi' tears.
 They hae need o' a canny cook that hae but ae egg to
 their dinner.
 They may ken by your beard what has been on your
 board.
 They ne'er saw great dainties that think a haggis a
 feast.
 They should kiss the guidwife that wad win the guid-
 man.
 They speak o' my drinking, but ne'er think o' my drouth.
 They that get a word o' soon rising may lie a' day.
 They that see you a' day winna break the house for
 you at night.
 Three can keep a secret when twa are away.

Thrift is a gude revenue.
 Time tint is ne'er to be found.
 Time and thinking tame the strongest grief.
 Time tries a'.
 Time heart and a's gane.
 Time thimble, time thrift.
 Tit for tat's fair play.
 To him that wills, ways are seldom wanting.
 Toom stalls mak biting horses.
 Truth will aye stand without a prop.
 Try your friend ere you need him.
 Twa words maun gang to that bargain.
 Virtue ne'er grows auld.
 Waes the wife that wants the tongue, but weel's the
 man that gets her.
 Want o' wit is waur than want o' wealth.
 War maks thieves, and peace hangs them.
 We are aye to learn as lang as we live.
 We are bound to be honest and no to be rich.
 Wealth has made mair men covetous than covetousness
 has made men wealthy.
 Wealth maks wit waver.
 Weans maun creep ere they gang.
 We canna baith sup and blaw.
 Wedding and ill wintering tame baith man and beast.
 Weel kens the mouse when the cat's out o' the
 house.
 Weel is that weel does.
 We'll never ken the worth o' water till the well gae
 dry.
 We maun live by the living and no by the dead.
 Wha can haud what will be away.
 Wha can help misluck.
 Wha can help sickness, quoth the wife, when she lay in
 the gutter.
 Wha comes oftener and brings you less.
 Wha daur bell the cat.
 Wha invited you to the feast.
 Wha wad misca' a Gordon on the raws of Strath-
 bogie.
 What better's the house when the daw rises soon.
 What may be done at any time will be done at nae
 time.
 What put that i' your head, that didna put the sturdy
 wi't.
 What's my case the day may be yours the morn.
 What's waur than ill luck.
 What we first learn we best ken.
 What winna do by might do by flight.
 What ye do when your drunk ye may pay for when
 your dry.
 What ye want up and down ye hae hither and yont.
 When a' men speak, nae man hears.
 When ae door steeks, anither ane opens.
 When friends meet, hearts warm.
 When he dies of age ye may quake for fear.
 When ilka ane gets his ain, the thief will get the
 widdy.
 When my head's down my house is theiked.
 When petticoats woo, breeks come speed.
 When the barn's fu' ye may thresh before the door.
 When the cap's fu', carry't even.
 When the cow's in the clout she soon runs out.
 When the guidman drinks to the guidwife, a' wad be
 weel.
 When the guidwife drinks to the guidman a's weel.
 When the heart's fu' o' lust, the mouth's fu' o'
 leasing.
 When the tod preaches, tak tent o' the lambs.
 When the tod wins to the wood, he caresna how mony
 keek at his tail.
 When the wame's fu', the banes wad be at rest.
 When the well's fu' it will rin owre.
 When wine sinks, words swim.
 When ye're gaun an' comin' the gate's no toom.
 When ye are weel, haud yoursel sae.
 When ye win at that, ye may lick aff a het girdle.

* All things are gone wrong.

† Something amiss.

‡ Bringing something under her arm.

When you're served, a' the geese are watered.
Where drums beat, laws are dumb.
Where the buck's bound there he maun bleet.
Wrang has nae warrant.

Ye're like auld maidens, ye look sae high.
Ye're like gude maut, ye're lang o' coming.
Ye're like Macfarlane's geese, ye hae mair mind o' your play than your meat.
Ye're like the chapman, ye're aye to handsel.
Ye're like the miller's dog, ye lick your lips ere the pock be opened.
Ye're like the cow's tail, ye grow backward.
Ye're like the tod, ye grow grey before ye grow gude.
Ye fand it where the Highlandman fand the tangs.
Ye hae fasted lang and worried on a midge.
Ye hae gotten the chapman's drowth.*
Ye hae gotten a ravelled hesp o't.
Ye hae ower foul feet to come sae far ben.
Ye hae put a toom spoon in my mouth.
Ye hae stayed lang and brought little wi' ye.
Ye hae taen the measure o' his foot.
Ye hae tint the tongue o' the trump.
Ye'll get nae mair o' the cat but the skin.
Ye'll hae baith your meat and your mense.†
Ye'll sit till ye sweat, and work till ye freeze.
Ye'll worry i' the hand, like M'Ewan's calf.
Ye look as sharp as a Lochaber axe new come frae the grindstane.
Ye look like Let-me-be.
Yelping curs will raise mastiffs.
Ye maun have it simmered and wintered.
Ye're a gude seeker, but an ill finder.
Ye're best when ye're sleeping.
Ye're bonny enough to them that lo'e ye, and ower bonny to them that lo'e ye and canna get ye.
Ye're busy seeking the thing that's no tint.
Ye're come o' bluid, and sae's a pudding.
Yer een's yer merchant.
Ye're feared for the day ye never saw.
Ye're gear will ne'er overgang ye.
Ye're never pleased, fu' nor fasting.
Ye're of sae mony minds, ye'll never be married.
Ye're sair fashed hauding naething thegither.
Ye're teeth's langer than yer beard.
Ye shape shoon by your ain shachled feet.
Ye wad be a gude piper's dog, for smelling out bridals.
Ye wad be gude to fetch the deil a drink.
Ye watna where a blessing may light.
Ye are a sweet nut, if ye were weel cracked.
Young folk may die, and auld folk maun die.
Your head will never fill your father's bonnet.
Your purse was steekit when that was paid for.
Your tongue rins aye before your wit.

LATIN PROVERBS AND PHRASES.

Ab initio. From the beginning.
Ab uno disce omnes. From a single instance you may infer the whole.
Ad captandum vulgus. To catch the rabble.
Ad finem esto fidelis. Be faithful to the end.

Anno Domini (A. D.) In the year of our Lord.

* Hungry.

† Offer a person a thing, and as he will not take it, you will at least have the credit of having made the offer.

Anno Mundi (A. M.) In the year of the world.
A posteriori. From the effect to the cause.
A priori. From the cause to the effect.
Arbiter elegantiarum. Master of the ceremonies.
Argumentum ad hominem. An argument to the man.
Ars est celare artem. The perfection of art is to conceal art.
Audi alteram partem. Hear the other party.
Auditio multa, sed loquere pauca. Hear much, but say little.
Auri sacra fames. The accursed appetite for gold.
Aut Cæsar aut nullus. He will either be Cæsar or nobody.
Basis virtutis constantia. Constancy is the foundation of virtue.
Beatus ille qui procul negotiis. Blessed are they who retire from toil.
Bona fide. In good faith; in reality.
Brutum fulmen. A harmless thunderbolt.
Cacoethes. An evil custom. Thus, cacoethes loquendi—scribendi. A rage for talking—scribbling.
Causus belli. The cause or reason for war.
Caput mortuum. The worthless remains.
Cede Deo. Submit to God.
Cede magnis. Give way to the powerful.
Cedant arma togæ. Let arms yield to eloquence.
Certum pete finem. Aim at a sure end.
Communia proprie dicere. To express common things with propriety.
Compos mentis. In a state of sane mind.
Concordia res parvæ crescunt. Small things increase by union.
Confide recte agens. Fear not while acting justly.
Contra bonos mores. Against good morals.
Corpus delicti. The body of the crime.
Credat Judæus apella. Let the circumcised Jew believe that.
Cui bono? To what good?
Currente calamo. With a running pen.
Data. Things given or granted.
De facto—de jure. From the fact—from the law.
Delectando pariterque monendo. By imparting at once pleasure and instruction.
Delenda est Carthago. Carthage must be destroyed. (The words of Cato.)
De mortuis nil nisi bonum. Let nothing be said of the dead but what is favourable.
Deo favente—juvante—volente. With God's favour—help—will.
Desideratum. A thing desired.
Desipere in loco. To play the fool at the right time.
Desunt cætera. The remainder is wanting.
Deum cole, regem serva. Worship God, serve the king.
Deus protector noster. God is our protector.
Dilige amicos. Love your friends.
Divide et impera. Divide and govern.
Dulce et decorum est pro patria mori. It is sweet and glorious to die for one's country.
Dum vivimus vivamus. Let us live while we live.
Est modus in rebus. There is a medium in all things.
Esto perpetua. Be thou perpetual.
Esto quod videris. Be what you seem to be.
Ex cathedra. From the chair; authoritatively.
Exempli gratia (E. g. and Ex. gr.) By way of example.
Ex nihilo nihil fit. Nothing produces nothing.
Ex officio. By virtue of his office.
Ex parte. On one part.
Ex pede Herculeum. Judge of the size of the statue of Hercules by the foot.
Experto crede. Believe an experienced man.
Extempore. Without premeditation.
Fac simile. Do the like: an engraved resemblance of handwriting.
Fama semper viret. A good name will shine for ever.
Familias firmat pietas. Devotion strengthens families.
Fas est et ab hoste doceri. It is allowable to derive instruction even from an enemy.

Felo de se. A suicide.
 Fiat justitia, ruat cælum. Let justice be done, though the heavens should fall.
 Fortuna favet fortibus. Fortune favours the bold.
 Fruges consumere nati. Men born only to consume food.
 Haud passibus æquis. With unequal steps.
 Hinc illæ lachrymæ. Hence proceed these tears.
 Id est (i. e.) That is.
 Id genus omne. All persons of that description.
 Imprimatur. Let it be printed.
 Impromptu. Without study.
 In forma pauperis. In the form of a poor man.
 In propria persona. In person.
 In re. In the matter of.
 In terrorem. In terror.
 In transitu. In passing.
 Ipse dixit. He himself said it: dogmatism.
 Judex damnatur cum nocens absolvitur. Guilt attaches to a judge when the guilty are suffered to escape.
 Jure divino—humano. By divine—by human law.
 Labor omnia vincit. Labour conquers every thing.
 Lapsus lingue. A slip of the tongue.
 Lex talionis. The law of retaliation.
 Locum tenens. A deputy or substitute.
 Magna est veritas, et prævalebit. The truth is powerful, and will ultimately prevail.
 Materiem superabat opus. The workmanship surpassed the materials.
 Medio tutissimus ibis. A medium course will be the safest.
 Memento mori. Remember death.
 Mens sibi conscia recti. A mind conscious of rectitude.
 Mirabile dictu. Wonderful to tell.
 Multum in parvo. Much in little.
 Mutatis mutandis. After making the necessary changes.
 Necessitas non habet leges. Necessity has no law.
 Nem. con. An abbreviation of *nemine contradicente*. Without dissent or opposition.
 Ne plus ultra. Nothing beyond—the utmost point.
 Ne quid nimis. Too much of one thing is good for nothing.
 Ne sutor ultra crepidam. Let not the shoemaker go beyond his last.
 Nisi Dominus frustra. Unless the Lord assist you, all your efforts are in vain.
 Noscitur ex sociis. He is known by his companions.
 Nota Bene (N. B.) Mark well.
 Obiter dictum. A thing said by the way, or in passing.
 Onus probandi. The weight of proof; the burden of proving.
 O si sic omnia! Oh that he had always done, or spoken thus!
 O tempora, O mores! Oh the times, oh the manners!
 Otium cum dignitate. Ease with dignity.
 Palmam qui meruit ferat. Let him who has won bear the palm.
 Pari passu. By a similar gradation.
 Par nobile fratrum. A noble pair of brothers.
 Particeps criminis. An accomplice.

Passim. Every where.
 Per fas et nefas. Through right and wrong.
 Per se. By itself.
 Poeta nascitur non fit. Nature, not study, must form a poet.
 Prima facie. On the first view, or appearance.
 Primæ viæ. The first passages: the upper part of the intestinal canal.
 Primum mobile. The main spring; the first impulse.
 Principiis obsta. Oppose the first appearance of evil.
 Pro aris et focis. For our altars and firesides.
 Pro bono publico. For the public good.
 Pro et con. For and against.
 Pro re nata. For a special business.
 Pro tempore. For the time.
 Quid nunc? What now?—Applied to a news-hunter.
 Quid pro quo. What for what; tit for tat.
 Quoad hoc. To this extent.
 Quod erat demonstrandum. Which was meant to be shown.
 Rara avis in terris, nigroque simillima cygno. A rare bird in the earth—very like a black swan.
 Reductio ad absurdum. A reducing to an absurdity.
 Re infecta. Without attaining his end.
 Requiescat in pace. May he rest in peace.
 Res angusta domi. Narrow circumstances at home.
 Respice finem. Look to the end.
 Seriatim. In order.
 Sic itur ad astra. Such is the way to immortality.
 Sic passim. So every where.
 Sic transit gloria mundi. Thus the glory of the world passes away.
 Sine die. To an indefinite time.
 Sine qua non. An indispensable condition.
 Status quo ante bellum. The state in which both parties were before the war.
 Suaviter in modo, fortiter in re. Gentle in the manner, but vigorous in the deed.
 Sub silentio. In silence.
 Summum bonum. The chief good.
 Suum cuique. Let every man have his own.
 Tabula rasa. A smoothed tablet.
 Tempora mutantur, et nos mutamur in illis. The times change, and we change with them.
 Toties quoties. As often as.
 Ubi supra. Where above mentioned.
 Vade mecum. Go with me: a constant companion. (Usually applied to a pocket-book).
 Veluti in speculum. As if in a mirror.
 Veni, vidi, vici. I came, I saw, I conquered.
 Vis inertie. Force or property of inanimate matter.
 Versus (v.) Against.
 Vice versa. The terms or cases being changed.
 Vi et armis. By main force.
 Viva voce. By or with the living or loud voice.
 Viz. (videlicet.) Namely.
 Vox et præterea nihil. A voice and nothing more.
 Vox populi, vox Dei. The voice of the people is the voice of God.
